THE award to Dr Georg von Békésy of the 1961 Nobel Prize for Physiology gives recognition to a remarkable achievement in the field of experimental biophysics Dr Békésy has had an unusual career Born in 1899 in Budapest and educated at the Universities of Bonn and Budapest, he has, since 1949, been senior research fellow in psychophysics at Harvard He has displayed outstanding skill as an experimenter, devising at all stages of his work new technical equipment, mechanical, optical and electrical, of great ingenuity His first remarkable contribution was a penetrating analysis of the vibrational responses to pure tones of the basilar membrane of the human cochlea A later outstanding achievement was his use of vibrating electrodes to explore and reconstruct the patterns of amplitude and direction of vibration induced in individual cell elements within the cochlea in response to pure tones of varying frequency and intensity His papers, written in clear, concise and graphic language, have exercised a profound effect on our concepts of the peripheral mechanism of hearing An edited selection of his earlier German papers has recently been translated into English by Prof E G. Wever, one of his American colleagues, and republished together with others in book form, *Experiments in Hearing* This is a substantial volume of 750 pages and incorporates a representative bibliography of the author's papers In 1961 Dr von Békésy was awarded the Gold Medal of the Acoustical Society of America

The Education Bill in Great Britain

THE Education Bill, which received its second reading in the House of Commons on November 13, has two purposes The first is to provide statutory authority for the reforms in the system of grants to students which were announced following the report of the Anderson Committee, the second is to reduce to two the number of school-leaving dates in the year, as recommended by the Central Advisory Council for England and Wales in the Crowther Report In moving the second reading of the Bill, the Minister of Education, Sir David Eccles, said that the local authorities, with which he had fully discussed the provisions of the Bill, readily accepted that the time had come to make the awards automatic when the student had both the qualifications and a place at a university, and Clause 1 laid this duty on the authorities as from September 1962, and gave the Minister power to define the extent of the duty. Sir David said that he had accepted the Anderson Committee's recommendation that the qualifications for an award should be two A-level passes in the General Certificate of Education, but it is necessary to provide for further qualifications which students may gain as they advance in technical colleges Clause 2 ensured that local authorities had full discretion to make awards for further education courses below the standard comparable with first-degree courses

The second fundamental principle of the new system is uniformity of treatment Sir David said that local education authorities now generally accept for the student's own maintenance during term the standard figures reviewed at intervals by their representatives and the Ministry In future there would be nationally prescribed rates and conditions of grant binding on all authorities for all items of a student's grant which could be dealt with in this way It was proposed to retain the means test in a relaxed way which would relieve about 10,000 more families from all contributions and those in the middle range of incomes would pay substantially less Grants for students in teacher-training colleges would be calculated in the same way as for university students, and those for students in technical colleges taking full-time courses comparable with degree courses would be similarly calculated The standard vacation grant had been revised and now applies throughout the income range of parents, while conditions for dependants' grants have been revised and broadened Students may keep up to £100 of private income, including income from scholarships and prizes, without deduction from their grant, and the Minister said he had appointed a Standing Advisory Committee with Sir Francis Hill as chairman to advise on matters relating to the size of the grant and the definition of 'comparable courses' The Committee had been asked to recommend revised rates of grant early in the New Year

Sir David said that under our present policies, the cost of education in Britain is rising at about 5 per cent a year, and awards to students now cost £35 million a year What is proposed under the Bill would add a further £10 million To abolish the means test altogether would add another £10 million, and Sir David said that if he and the Secretary of State for Scotland were allowed to spend a second £10 million, they thought they could spend it to better advantage in other parts of the service Under Clause 3 of the Bill, State Scholarships would disappear, but the Minister intends to retain the scheme for mature State scholars, and his powers to operate the State studentship scheme of awards for postgraduate students in arts subjects are also continued As regards school leaving, under the Bill a child who reaches fifteen in the months September–January must stay at school until the end of the Easter term, if he reaches fifteen after the end of January, he must stay to the end of the summer term The Bill also applies to Scotland the automatic awards, uniformity of treatment, revised income scale and other improvements, but the Scottish Education Department will itself make the awards to students in universities and similar institutions of higher education

Scientists and Engineers in the U.S. Federal Government

A REPORT, *Scientists and Engineers in the Federal Government, October* 1958 (NSF 61–43. Pp. vi+44 (Washington, D C Government Printing Office, 1961) 35 cents), issued by the National Science Foundation, also includes some data on trends in Federal employment of scientists and engineers since the previous report (covering the year 1954) In 1958 the Federal Government employed about 8 per cent of all full-time 'white-collar' workers, an increase of 20 per cent on 1954 Of these 121,000, 55,000 were engineers, 21,000 were biological scientists and 18,000 physical scientists The Department of Defense was the largest employer, and some 75 per cent of the total were employed outside the District of Columbia About 42,000 were engaged in research and development, more than half being in the Department of Defense and 20 per cent in the physical sciences About 100,000 technicians were employed by the Federal Government, 35,000, including 21,000 engaged in nursing, being employed in the health fields, 12,000 were employed in biological and less than 5,000 in the physical sciences, and of the total, less than 15,000 were engaged in research and development, about half of whom were employed by the Department of Defense, mostly (86 per cent) as engineering or mechanics technicians

National Health Service

OVERSEAS interest in the British National Health Service has led the Pharmaceutical Society of Great Britain to prepare an informative booklet which aims to identify the historical roots from which the present Service has grown, to explain a little of the complex financial basis, to describe the general structure, and, in more detail, the pharmaceutical services (*The British National Health Service. a Short Survey with particular reference to the Pharmaceutical Services* Pp. ii+22 London The Pharmaceutical Press, 1961 5*s*) Mention is also made of the main findings of some of the committees that have deliberated from time to time on the various problems affecting the Service Although the booklet aims especially at supplying information to pharmacists and others overseas, it may also provide a suitable introduction to the intricacies of the profession for newly qualified pharmacists or pharmacy students in Britain. It should also serve as a refresher course for those pharmacists who, although familiar with the day-to-day forms and procedures of the Service as it affects them, are sometimes less sure about the general structure of which they form so integral a part

The United Kingdom and the Common Market

UNDER the title *The Common Market and the United Kingdom* the Westminster Bank, Ltd, has issued an admirable concise guide to the European Economic Community and the possible effects on Britain of membership (Pp 30 London Westminster Bank, Ltd., 1961) After a brief introduction which notes the complications arising out of Britain's position in the Commonwealth, her obligations to the European Free Trade Area and the special problem presented by agriculture, the pamphlet describes the European Economic Community, its organization and progress and then seeks to assess the effects on the United Kingdom of entry into the Common Market, including the effects on industry, on agriculture and on the consumer

The Polish Academy of Sciences

IN the *Review of the Polish Academy of Sciences* for January–March 1961 (No 1, Vol VI), W Nowacki assesses the research plans of the Academy's agencies for 1961–65, and S Zolkiewski the present state of the social sciences and the humanities in Poland. Besides B Swietochowski's account of the scientific work of the Wroclaw Agricultural College, which includes a full bibliography, the *Review* includes notes on the several research centres for thermoenergetics, forestry research, pharmacological research and general theory of organization and on the Institute of Biochemistry and Biophysics and the Basic Raw Material Research Centre of the Institute of Physical Chemistry

Nature Conservation in Western Malaysia

A SPECIAL issue of the *Malayan Nature Journal* has been prepared to mark the twenty-first anniversary of the Malayan Nature Society ("Nature Conservation in Western Malaysia", 1961 Edited by J Wyatt-Smith and P B Wycherley. Pp viii+261+44 plates Kuala Lumpur The Malayan Nature Society, 1961 Soft back, 12*s* 6*d*; hard back, 17*s* 6*d*) It contains forty-five articles by forty-one contributors dealing with such topics as the Malayan Nature Society, 1940–61, conservation and education, the Malayan Forest Department and conservation, river control and conservation in Malaya, conservation problems of Malaya's hill stations, conservation in Penang; nature protection in North Borneo, ferns in Singapore, limestone hills near Ipoh, Batu caves, Kuala Lumpur, cave archæology in Malaya, the distribution of elephant, rhinoceros, seledang and tapir in the King George V National Park, Malaya, the Shwe U Daung, a rhinoceros sanctuary in Burma, the Udjung-Kuolon Nature Park, Java, Mount Kinabalu, North Borneo, and the Bako National Park, Sarawak There are also a number of articles dealing with wild-life conservation in other lands E J H Corner, now reader in taxonomy at the University of Cambridge, and formerly assistant director of gardens, Straits Settlement, Singapore, contributes a stimulating introduction.

Insects as Social Animals

THE fourth congress of the International Union for the Study of Social Insects was held in Pavia during September 9–14, at the invitation of the president of the Italian section of the Union, Prof Carlo Jucci Some two hundred people took part and 72 papers were read There were symposia on endocrinology, caste differentiation, symbiosis and gregarism, and sections devoted to bees and wasps, ants and termites Among the contributors were Prof P-P Grassé (evolution of symbiosis in termites), Prof C Jucci (comparative endocrinology of social insects), Prof M Luscher (hormonal regulation of development in termites), Prof K Gosswald (acceptance and rejection of radioactive markers by solitary and social insects), and Prof J B S Haldane (statistical analysis of some data on ant and wasp behaviour) A well-arranged exhibition was another feature of the congress This included historical documents relating to earlier workers on social insects—Grassi, Silvestri, Forel and others, scientific exhibits ranging from photographs of African ant-galls and Australian termite mounds, to anatomical preparations, and a section on control measures, which included exhibits showing the progress of termite control in Italian libraries, and the successful introduction of the wood ant, *Formica rufa*, for the biological control of pests in Italian forests The proceedings of the congress are to be published in the series *Symposia Genetica* of the L Spallanzani Zoological Institute, University of Pavia

Leucocyte Migration in Inflammation

SIR Howard Florey and L H Grant, in an article appearing in a recent issue of the *Journal of Pathology and Bacteriology* (82, No 1, July 1961), report investigations of the passage of leucocytes through the walls of blood vessels inflamed by ultra-violet light in rabbit tissues using electron microscope techniques No clear morphological evidence was obtained that the surface of the endothelium became 'sticky', although occasionally electron-dense material was seen in relation to the endothelium The leucocytes penetrate the endothelium by thrusting out pseudopodia, possibly down cell junctions, and passing through until they reach the basement membrane, collagen fibres and preendothelial cells. It would appear that they then usually move parallel to the endothelium until they gain exit to the surrounding connective tissue. The granules of the polymorphs do not seem to undergo any changes during migration. Monocytes behave in the same way as polymorphs. Vacuoles of unusual appearance are seen in the endothelium after ultra-violet stimulation but not after mechanical 'insult'.

Chalk River Atomic Energy Instrumentation Conference

The complete set of five parts of the proceedings of the Sixth Tripartite Instrumentation Conference, which was held at Chalk River, Ontario, during April 20–24, 1959, is now available (Edited by J. E. Woolston and S. J. Townsend. Part 1: *Reactor Instruments*. Pp. xi+214. 5 dollars. Part 2: *Radiation Dosimetry*. Pp. xi+145. 3 dollars. Part 3: *System and Component Reliability*. Pp. viii+19. 1 dollar. Part 4: *Instruments for Nuclear Physics*. Pp. xi+212. 5 dollars. Part 5: *Radiation Detectors*. Pp. ix+76. 2 dollars. Chalk River, Ontario: Scientific Document Distribution Office, Atomic Energy of Canada, Ltd., 1960. 15 dollars the set). The participants consisted of members of the United Kingdom Atomic Energy Authority, Atomic Energy of Canada, Ltd., and various scientific and industrial laboratories in the United States of America. Some of the articles are abbreviated, but the discussions are given in full. Part 1 (thirty-one contributions) deals with reactor instruments and includes brief reviews of reactor instrumentation practice in the United Kingdom and at Savannah River. In the first three articles in Part 2 (twenty-nine contributions), which is concerned with radiation dosimetry and health instruments, descriptions are given of the health-physics instrumentation at the Brookhaven National Laboratory and at the Hanford Atomic Products Operation, Richland, and of radiation dosimetry at Chalk River. Part 3 (five contributions) on system and component reliability includes a summary of the reliability performance of equipment at Harwell during 1953–56, and an analysis of the component failure at Chalk River during 1956–59. A wide range of electronic, including transistorized, equipment is covered in Part 4 (thirty-three contributions), which deals with instruments for nuclear physics, and in Part 5 (fourteen contributions), on radiation detectors, various forms of ionization chambers, fission chambers, scintillation counters and semi-conductor radiation detectors are described.

Artificial Earth Satellites

The memoir, "Artificial Earth Satellites", recently issued by the Radio-Electronics Section of the British Astronomical Association (39, No. 2, August 1961. Pp. viii+160. Hounslow West, Middx: British Astronomical Association, 1961. 20*s*.; 3 dollars), is divided into two sections. The first section (contributed by J. Heywood) is devoted, first, to an introductory survey of Earth satellites, and secondly, to a historical review of the radio measurements made by members of the British Astronomical Association and Radio Society of Great Britain on *Sputniks* 1 and 2. The second section (contributed by various authors) is concerned with the techniques of visual and photographic satellite observation, the use of charts for the prediction of satellite positions and the graphical derivation of apparent tracks for satellites. The memoir, compiled and edited by J. Heywood, should be of interest to all amateur observers of artificial Earth satellites.

University News: London

The title of professor of theoretical physics has been conferred on Dr. P. T. Matthews, in respect of his post at the Imperial College of Science and Technology. The following have been appointed to readerships: Dr. K. A. Kermack, vertebrate palæontology at University College; C. H. Lack, bacteriology at the Institute of Orthopædics; Dr. J. E. Prentice, geology at King's College; Dr. M. Schacter, physiology at University College; Dr. Gordon Smith, virology at the London School of Hygiene and Tropical Medicine; Dr. Maynard Smith, zoology at University College; Dr. G. L. Watson, mathematics at University College.

The Research Report 1958–61 of the City and Guilds College gives a very readable account of the work carried out in the five engineering departments of the Imperial College of Science and Technology—Aeronautics, Chemical Engineering and Chemical Technology, Civil Engineering, Electrical Engineering and Mechanical Engineering (Pp. v+96. London: Imperial College of Science and Technology, City and Guilds College, 1961). While the account makes clear the importance of the contribution of the College to present-day technological advances, it is left for the reader who is interested in particular researches to approach the relevant Department direct for further information. No names of those responsible for the various researches are given, nor is a list of published papers included.

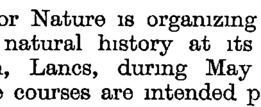
Announcements

The Imperial Forestry Institute at Oxford has been re-named the Commonwealth Forestry Institute.

The next symposium of the Society for the Study of Development and Growth will be held during June 24–27, 1962, at "Asilomar", Pacific Grove, Monterey Peninsula, California. The subject of the symposium will be "Cytodifferentiation and Macromolecular Synthesis".

The Council for Nature is organizing two seven-day courses on natural history at its Brantwood Centre, Coniston, Lancs, during May 12–19 and May 19–26. The courses are intended primarily for amateur naturalists. Further information can be obtained from Stanley Jeeves, Council for Nature, Brantwood, Coniston, Lancs.

Errata. The structural formula of 3-methyl-7-chloro-1,2,4-benzothiadiazine-1,1-dioxide (*SRG* 95213) was misrepresented in the letter entitled "A Non-diuretic Benzothiadiazine with Anti-hypertensive Properties" which appeared on p. 176 of the October 14 issue of *Nature*. The correct formula is:



In the communication entitled "Preparation and Determination of Sulphosalicylo-soluble Proteins using Tannin", by Prof. W. Mejbaum-Katzenellenbogen *et al.*, in *Nature* of October 21, p. 262, par. 2, last line, for "an appropriate conversion factor should be used" read "no conversion factor should be used".

THE WATER RESEARCH ASSOCIATION

NEW RESEARCH STATION

THE Water Research Association (director, Dr. R. G. Allen) invited its members on September 20 to inspect the permanent Research Station on the River Thames at Medmenham, in Buckinghamshire, into which it moved earlier this year. The Association was founded by water undertakings and is now in receipt of grant-aid under the scheme for industrial Research Associations operated by the Department of Scientific and Industrial Research. Previously it had been in temporary accommodation at Redhill, and with the move into specially designed buildings on a site where there is a plentiful supply of raw water, and provided with appropriate facilities for experimentation, it can be seen that the organization has now attained its full stature as an established Research Association.

The removal to new laboratories made it possible both to extend the scope of the research on hand and to begin programmes in new fields. The internal organization was expanded to comprise the following eight divisions: chemistry; physics; biology; hydrology; plant process; information; workshop services; administration. Thus there are now staff and facilities for work on every technical aspect of providing potable water.

Perhaps the most interesting structure in the new buildings is the Pilot Plant Laboratory, which has a total floor area of about seven thousand square feet, with a maximum roof height of thirty-six feet. This laboratory is intended primarily for the testing of equipment and techniques on the industrial scale; raw water is brought in from the River Thames and the construction and fittings are designed specifically for such work.

Specialized laboratories include those for physics, and for physical chemistry, general chemistry, coagulation chemistry, chemical instruments, microbiology and hydrology. There is a well-equipped machine shop. The library is being enlarged with the object of maintaining a unique collection of the literature relating to certain technical aspects of the water industry which are not indexed together elsewhere.

Chemistry Division

In the Chemistry Division the main work has been on the use of coagulation in water treatment. In this commonly used chemical process the fine suspended particles of clay which cause turbidity in water are made to coagulate into a floc of larger particles by the addition of a coagulant such as aluminium sulphate, and are then removed comparatively easily by settlement.

This investigation has thrown a completely new light on the mechanism of coagulation. It has been found that the range of values of *p*H in which the coagulation process is most efficient in removing turbidity corresponds to that in which the hydrolysis product is most rapidly flocculated, that concentrations of various coagulants which are equivalent in terms of aluminium concentration are not equivalent in terms of coagulant efficiency, and that there is at least a rough relationship between the relative coagulant efficiency and the amount of hydrolysis product that is precipitated immediately on reaction of the coagulant with water. This suggests that the mechanism of the clarification of turbid water is not coagulation in its true sense; the only coagulation that takes place is that of the hydrolysis product, and the clay particles which constitute the turbidity are carried down in the mass of flocculating hydroxide particles. The precise nature of the interaction between the clay and the hydroxide is not yet clearly understood, but is being investigated.

A number of coagulants have now been studied in some detail, and other coagulants and materials assisting the coagulation process are also being evaluated.

Coagulation processes are also used for the removal of colour from water. To provide the quantities of the colouring matter (complex organic acids derived from soil humus) required for research, a technique has been developed in which this material can be isolated from raw Thames water at rates of flow of up to 100 gallons per hour. It is proposed in the near future to begin isolating the organic colour from a number of raw water sources in addition to that on the site, and to study the way these materials behave in flocculating systems.

An analytical section has been established within the Chemistry Division, and is making a systematic study of methods used in the analysis of potable waters. This section will investigate new techniques for the measurement of every aspect of water quality, and this experience will be of great value if eventually a water quality network is established in Britain, similar to that which operates in the United States of America.

Physics Division

The Physics Division is concerned with all the physical aspects of water distribution. Its principal research programmes at present relate to the application of plastic materials to the construction of water mains and service pipes, to methods of instrumentation (particularly for the detection of leaks) and to mathematical analysis of flows and pressures in water distribution networks.

In an investigation on plastic pipes it is hoped to establish optimum design criteria for long-term service. Plastics react to variations of stress and temperature in a more complicated way than iron and steel, and as their long-term strengths are not precisely known, deliberately conservative ratings are now being used. Progress has already been made towards determining the long-term effect of variations of pressure in plastic water-distribution mains, employing accelerated tests, and the present programme relates to the measurement and specification of impact strengths. The impact resistance must of course be high enough to withstand reasonable shock loads in transit, when being laid, or when other services are being installed in the ground alongside.

It is estimated that leakage from water distribution systems in Britain exceeds 10 per cent of the

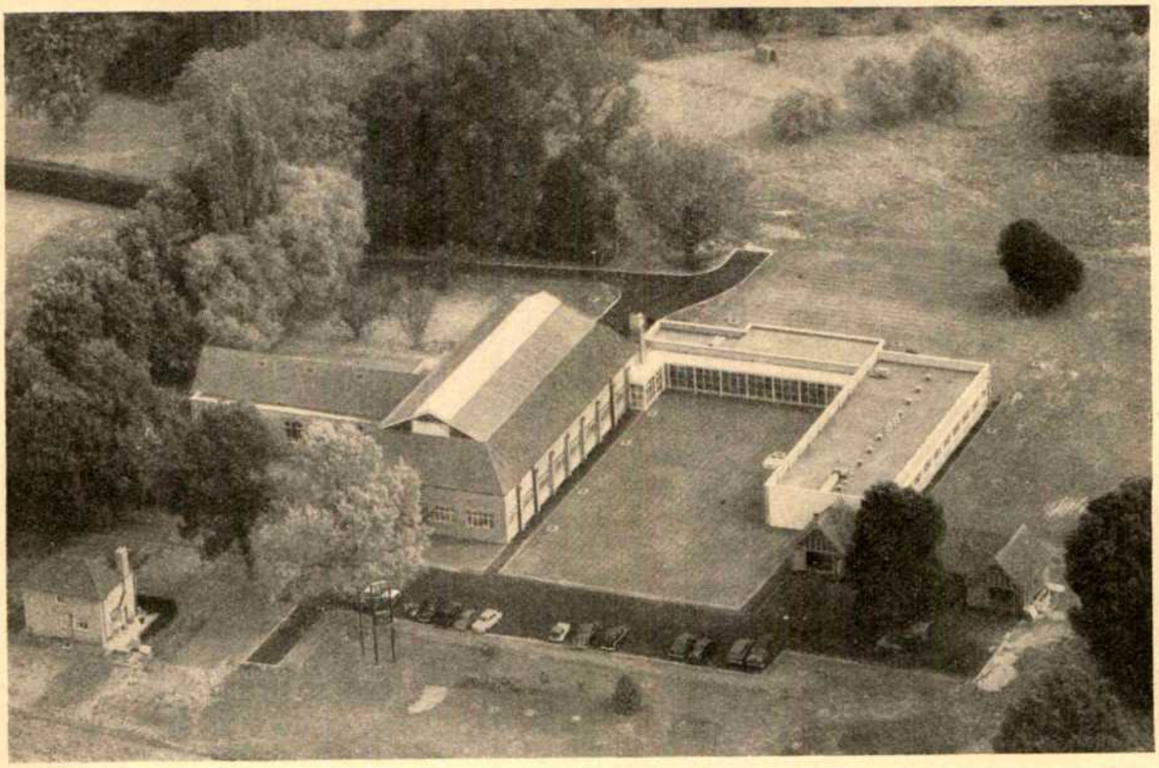


Fig. 1. The new Research Station of the Water Research Association, at Medmenham, near Marlow, Buckinghamshire. The grounds extend nearly to the River Thames, from which water is taken for experimental purposes

input, and a strong economic demand exists therefore for a device which will accurately locate leaks from buried water mains. The object of the programme in this respect is to develop a telemetering system in which an instrument carrier will be drawn along inside the pipeline and will transmit readings to an observer on the ground surface. Plunger devices (termed 'ferrets', 'go-devils' or 'pigs') which are driven through distribution mains by the fluid pressure are already in use for cleaning and other purposes, and such devices would also be suitable for carrying instruments. The first phase of the programme has therefore been the development of suitable signalling equipment, and devices have now been demonstrated which transmit a magnetic signal from a small piece of equipment inside a buried pipeline of any material including iron and steel, through the earth or other top filling, to light-weight portable receiving equipment.

While the work on the development of a complete telemetering system continues, the method of transmitting a signal from inside a buried pipeline is being put to good use in the design of a device to detect the position of a 'ferret' in service. This has now reached the prototype stage. An electro-magnetic beacon is attached to the 'ferret', so that its position can be found by moving the receiving equipment until the signal is loudest. It has been a major objection to the use of 'ferrets' that if they should stop in the pipeline it might be a very difficult matter to find and recover them, and a reliable 'ferret' detector should encourage their wider use.

As areas of water supply are extended, and rising demand brings many of the supply mains nearer their limits of capacity, it becomes increasingly important that it should be possible to calculate pressures and flows rapidly and accurately under existing and postulated conditions of supply and demand. Such calculations are altogether too time-consuming to be done by hand, and investigations have therefore been made of the use of both analogue and digital computers to produce methods of rapid and precise computation.

Plant Process Division

The Plant Process Division was set up when the Association had moved to its new establishment. The present programme is as follows: to investigate existing water-treatment processes; to develop from the findings of the Chemistry Division new processes which may be applied to full-scale waterworks plant; to investigate particular problems which may occur in the plant of members of the Association.

The equipment which is at present being designed will occupy a large part of the Pilot Plant Laboratory, and will include two treatment processes, one as a standard of reference. It will be large enough to ensure that the processes developed in it can be transferred to full-scale plant without further difficulty, while still being small enough to be flexible in operation. This plant will use raw water from the Thames at a maximum rate of about a thousand gallons per hour.

Hydrology Division

The study of hydrological problems is the responsibility of another newly established Division. The work of the Water Research Association in this field is part of an integrated national programme, and its present aims are: to encourage the improvement, both in quality and quantity, of hydrological measurements made by water undertakings; to advise the water undertakings in membership on ways of using their own hydrological data; to co-operate in the scientific study of evaporation and rainfall measurements in upland catchment areas of the British Isles

The Hydrology Division is devoting its main attention at present to surface waters The water industry is immediately interested in calculating effective reservoir capacities, and in the effects of different types of land use on water yield Several continental countries and the United States of America have made considerable progress in this respect and their results, although not directly applicable to the very different conditions in Britain, suggest a number of ways by which substantially increased yields might follow if the necessary data were determined and applied The research aspects of the work of the Hydrology Division work are designed to assist in this.

In addition, since 30 per cent of the raw water taken by water undertakings in the British Isles comes from underground sources, these must be assessed as regards their long-term yield in terms of infiltrating rainfall Natural replenishment by this means is a very slow process, but artificial replenishment by pumping from surface water sources offers storage at low capital cost This method is already in use in Sweden, Germany, The Netherlands and the United States of America, the Association's programme provides for research to assist in collecting reliable data and overcoming technical difficulties

Biology Division

The biological aspects of the water supply process are clearly of the utmost importance, not only because biological purity is required equally with chemical purity but also because biological as well as chemical processes are employed in water purification

The Biology Division has only recently been established, and is still engaged on a preliminary examination of the problems. It is expected that its first programmes will be concerned with aspects of water sterilization, with the development of faster techniques for bacteriological examination and with the control of algae in stored waters

Information Division

The objects of the information services are to see that new information from all sources is readily available to members, to provide assistance with day-to-day problems where the necessary information already exists, and to maintain communication with the water industry, other research establishments and other organizations with appropriate interests throughout the world

In addition to the material supplied to staff and members by the library, numerous technical inquiries from members are answered The staff of the Association is in a position to accumulate extensive experience of such problems, to maintain contact with specialists and to keep abreast of the published information

The problems presented are normally within the experience of the technical staff of an undertaking but outside their special province They cover a very wide range of topics, a typical selection might include complex cases of corrosion, attacks by insects (even on polythene water-supply pipe), the infestation of water supplies by various organisms, the chemical contamination of supplies, and such practical problems as the protection of reservoirs from birds

In addition to its technical papers the Association publishes a periodical, *Water Research News*

The Future

In its recent annual report, the Council of the Water Research Association comments "It is now apparent that considerable changes will be required in the nation's water systems if the rapid increases in agricultural and industrial demands are to be met everywhere The techniques of every stage of the water supply process are open to review, and a large part of the work must properly fall on the Water Research Association"

A visitor to the Water Research Association will realize that this consideration underlies all the planning at the new Research Station

MUSCLE RECEPTORS

THIS year the University of Hong Kong, as part of its golden jubilee celebrations, held six symposia during September 11–16 One of these, under the chairmanship of Prof. Ragnar Granit (Stockholm) was on muscle receptors It was organized by Prof D Barker, professor of zoology There were about thirty participants, who represented both the physiological and histological aspects of work on receptors in mammalian muscle The muscle spindle was considered from many angles and the papers, which ranged from accounts of the exacting work of electrical recording and single nerve fibre stimulation to details of the intricate structure of spindle innervation were given to full audiences and provoked lively discussions

Prof Granit opened the proceedings with a summary of much of the earlier work and a statement of some of the outstanding problems A special lecture by Sir John Eccles (Canberra), who was unable to be present, on the "Central Connections of Muscle Afferent Fibres", was read by Prof A K McIntyre (Otago, New Zealand) In the papers and demonstrations that followed, evidence was given of new advances which we may expect to see developed further in the future H Shimazu and T Hongo (Tokyo) directed attention to brain-stem influences on the motor supply to muscle spindles, while E Eldred (California) spoke of cerebral influences McIntyre considered that any discharges passing up muscle nerves and reaching the cerebrum probably came from Pacinian corpuscles and joint receptors and not from spindle primary endings Y Laporte (Toulouse) described elegant work in which both the primary and secondary afferent endings in a single spindle could be subjected to controlled stimulation of the spindle motor nerves and the responses compared C. Eyzaguirre (Salt Lake City) spoke of spindle motor innervation and described how some of the intrafusal muscle fibres were actually seen to contract slowly I A Boyd (Glasgow) gave a graphic account, with many beautiful colour slides, of the whole structure of muscle spindles in the cat, based on de-afferented and de-efferented material and much work on nerve fibre spectra He directed particular attention to the possibility of a double motor innervation D Barker (Hong Kong) and his co-workers, N K Chin, M N Adal, M C Ip and M Cope, also described much detailed work on the structure, nerve spectra and distribution of spindles in cat muscles It became obvious that there are points of great interest to both physiologists and histologists still needing to be settled about the complexity of the motor innervation of spindles

The mechanisms by which sensory endings initiate electrical discharges were considered by C C Hunt (Salt Lake City), using the simpler Pacinian corpuscle The electron micrographs shown by M C R. Merrillees (Melbourne) gave an insight into the ultrastructure of both spindle and tendon organ endings and their relation to underlying tissues A S Paintal (New Delhi) directed attention to the less well-known muscle receptors, with small nerve fibres, which probably subserve pressure and pain K S Lim (Indiana) also spoke of the responses of these endings Other papers dealt with pharmacological studies of spindles (J E Pascoe, London, and H -D Henatsch, Gottingen), spindle numbers and distribution (Eldred), differentiation of primary and secondary ending discharges (S Cooper, Oxford), the potentiation of motoneurones by spindle discharges and also human experiments on reflexes involving muscle receptors (S Homma, M Kano and K Takano, Chiba, Japan)

The ideal conditions under which the symposium was held both in the Department of Zoology and in the beautiful surroundings of Hong Kong gave many opportunities for discussions in small groups which did much to bring to light problems of structure and function that may be solved by mutual efforts of the workers in the two fields

The Hong Kong University Press plans to publish the Proceedings early in 1962 SYBIL COOPER

CHEMOTHERAPY OF VIRUS DISEASES

AT a meeting of the Fine Chemicals Group of the Society of Chemical Industry held in the Wellcome Foundation on October 6, the subject under discussion was research on the chemotherapy of virus diseases There are two ways in which this subject can be approached What might be called the rational approach requires an investigation of the essential components of virus multiplication with special emphasis on those steps which could be readily inhibited Thus, many substances are known that will inhibit the synthesis of viral nucleic acid or viral protein or that will block the supply of energy required for virus multiplication The problem is not how to inhibit virus growth but how to inhibit it selectively, without at the same time damaging the host cells The second approach, the empirical one, seems to have been the favoured approach, and one which has had more success so far

Dr A Isaacs (National Institute for Medical Research) presented the first paper, on interferon Interferon was first found during an investigation of the phenomenon of viral interference, in which it seems to play an important mediating part Further investigations suggest that it may also play a part in the immune processes that lead to recovery from virus infections

Interferon is a protein of molecular weight 63,000 which is produced by cells of a number of different vertebrates in response to infection with a large number of different viruses Its antiviral activity is usually more apparent in cells of the animal species in which it was made However, it is active against a wide range of animal viruses although there are differences among viruses in their sensitivity to interferon It does not prevent adsorption or penetration of virus but it inhibits the replication of viral ribonucleic acid. This probably results from inhibition of an oxidative process of the cell which supplies the energy for viral synthesis The inhibition seems to affect viral synthesis much more than normal cellular syntheses, however, since human thyroid cells can divide at a rate not grossly different from that of normal cells in the presence of a large amount of interferon

There is growing evidence that antibody may play a less important part in the processes of recovery from virus infections than has been thought hitherto, and that interferon may play a more important part This was shown first by experiments in chick embryos of different ages, in which recovery from virus infections is found to be closely related to development of sensitivity to interferon Secondly, persistence of virus in the lungs of mice of different ages was found to be inversely related to the production of interferon in these animals Thirdly, two ways of inhibiting the interferon mechanism *in vitro*, namely, increased oxygenation and treatment with cortisone, both have a detrimental effect on the course of virus infections *in vivo* These findings point to the conclusion that interferon may play an important part in our ability to recover from virus infections and they suggest that it might be possible to assist natural recovery from virus infections by giving interferon therapeutically This has been carried out successfully in some virus infections of animals and it is hoped that preliminary trials of its action in man will begin shortly

The second paper was given by Drs R Hull and E W Hurst (Imperial Chemical Industries. Ltd.) on structure activity in various heterocyclic compounds Material tested for possible antiviral activity was obtained from products synthesized for other biological assays, from the synthesis of analogues obtained in the course of following up an antiviral lead already found in the department or elsewhere, and from the synthesis of possible antimetabolites to viral nucleic acid Heterocyclic compounds constituted the largest section of organic compounds tested and a review was given of structure–activity relationships that had been found in the acridines 'Mepacrine' was the most active and showed antiviral activity against equine encephalomyelitis, Rift Valley fever and louping ill viruses

In evaluating experimental work it was important to take into consideration the complex of cell and virus that was studied Examples were given of compounds which reduced the growth of viruses in the chick embryo but which were not appreciably active in the mouse. On the other hand, 'Mepacrine', which was active against equine encephalomyelitis virus in the mouse and adolescent rat, was inactive against this virus in the chicken, guinea pig, rabbit and monkey.

Work on simple antimetabolites, in which the furan ring had been substituted for the ribofuranoside moiety in the nucleoside, had led eventually to certain tetrahydropyrimidines which showed activity against viruses of the psittacosis-lymphogranuloma-trachoma group both in the chick embryo and in the mouse. One, 17,025 [5-methoxycarbonyl-6-methyl-4-(5-nitrofuryl)-2-oxo-1,2,3,4-tetrahydropyrimidine] which was sparingly soluble in water, had very low toxicity and was both effective and non-irritant when given by the intramuscular route. It showed, weight for weight, rather less than one-tenth of the activity of chlorotetracycline. Its clinical use might be envisaged (for example, against trachoma) when it was desirable to control an infection by infrequent parenteral therapy rather than by prolonged topical application or by frequent oral dosing.

The third paper, by Drs. D. J. Bauer and P. W. Sadler (Wellcome Laboratories), was concerned with the antiviral action of derivatives of isatin β-thiosemicarbazone on viruses of the pox group. These compounds are known to show antituberculous activity and they were later shown by American workers to have some antiviral action against vaccinia virus. However, the latter work was not followed up until the group at the Wellcome Laboratories commenced detailed investigations of a number of derivatives of isatin β-thiosemicarbazone on a number of different members of the pox virus group. Perhaps the most striking finding has been the selectivity of action of these compounds. Thus, isatin β-thiosemicarbazone and some of its derivatives are very active against vaccinia but have no activity against ectromelia virus; conversely, isatin β-4′ 4′-dialkylthiosemicarbazone and related compounds are highly active against ectromelia but not at all active against vaccinia virus. This specificity should provide an important clue to the mode of action of these compounds. To the authors it suggested that these compounds were not acting on some cellular enzyme required for viral synthesis, but that they were acting directly on the virus itself.

A most interesting aspect of this work is the finding that *N*-ethylisatin β-thiosemicarbazone, in doses of 0·03 and 0·015 mgm. twice daily for five days, protected infant mice (less than six days old) against fatal infection by the viruses of alastrim and variola major. Dr. Bauer discussed at some length the question of the importance of the treatment of smallpox in these days of vaccination and he concluded that there was a strong case for trying out these compounds in man and that it was reasonable to expect that a specific anti-smallpox drug would be in use within the not too distant future.

ALICK ISAACS

PHOSPHOLIPIDS AND SULPHOLIPIDS

DR. M. MACFARLANE, joint chairman with Prof. D. D. Eley of the joint meeting of the Biochemical Society and the British Biophysical Society on "Phospholipids and Sulpholipids", which was held at the School of Pharmacy, University of London, during October 5–6, underlined its significance by a quotation from the Macleans (1927)[1]: "When we consider the obscurity in which the chemistry of the phospholipids has been shrouded, it is easy to understand that many of the properties and functions ascribed to these bodies are based on little more than imagination." Thirty years later imagination remains in plenty, but an immense amount of accumulated factual evidence was presented at the meeting. The chemical, physical and physico-chemical problems surrounding phospholipids challenge all scientists interested in the structure and functions of the living cell.

With the advent of recent analytical procedures involving chemical[2,3] or enzymatic hydrolysis, paper and silicic-acid chromatography[4], the compositional detail of many animal and plant tissues is progressing fast. Consequently, the phospholipid chemist of to-day recognizes phosphatidylglycerols, phosphoinositides, the classical ester phosphatides having either serine, ethanolamine or choline as the nitrogenous base, the plasmalogens, being analogous to the phosphatides, but with an aldehyde in place of a fatty acid, the sphingomyelins, the complex phosphoinositols and finally the lysophosphatides. Among many most recent compositional details reported at the meeting was the observation by Dr. G. R. Webster that the ethanolamine base in brain white matter is predominantly present in plasmalogen instead of the more usual phosphatidyl ethanolamine. Dr. E. Lederer, withdrawing earlier claims, pointed out that mycobacteria do not appear to contain any nitrogenous base phospholipids but do yield mixtures of phosphatidyl-inosito-mono, di- and tri-mannosides. Of great interest, however, was his report on the structure of the phosphatidyl-inosito-dimannoside, and of his proof that the 6-*O*-α-D-mannopyranosyl-α-D-mannopyranose is inositol linked, the dimannosides alone being almost as effective as *BCG* vaccine in the protection of animals against tuberculosis.

In plant chloroplasts the major anionic lipids are phosphatidylglycerol and the sulpholipid, 6-sulpho-α-D-quinovopyranosyl-(1 → 1′)-2′,3′ diacyl glycerol. The precise formulation of the latter compound has been established by Dr. A. A. Benson in an elegant analytical procedure. The presence of lipid lamellæ in plant chloroplasts and the high-rate of incorporation of carbon-14 dioxide, phosphorus-32 labelled phosphate and sulphur-35 labelled sulphate ions into the anionic lipids during photosynthesis points to at least two functions of phospholipids—namely, interfacial orientation with concomitant orientation of adjacent molecules, such as enzymes, and involvement in translocation of metabolic products.

With commercially available gas chromatography apparatus, each phosphatide can now be examined in terms of its fatty acid composition. This further stage in the dissection of phospholipids was reported on by Dr. G. M. Gray, who compared the mean fatty acid composition of normal tissue phospholipids with those from Landschutz ascites tumour cells. Surprisingly, and perhaps of fundamental importance, the tumour cell phospholipids showed far less variation in the kind of fatty acid acylated. For example, stearic is the predominating saturated acid in all tumour phospholipids, thus differing from normal tissues in which palmitic acid is the major saturated acid of phosphatidyl choline and choline plasmalogen

Prof L L M van Deenan and his colleagues at Utrecht rightly argued that a better understanding of the physical properties to be attributed to the fatty acids and to their particular position in the phosphatide molecule would clarify the biophysical properties of the phospholipid Reporting a remarkable programme of syntheses involving re-acylation of L-α glyceryl phosphoryl choline, with fatty acids of varying chain-length, Prof van Deenan was able to contribute experimental results obtained from his semi-synthetic material and relate it to many of the chemical and biophysical aspects covered during the meeting Perhaps the most significant advance so far resulting from the use of these re-acylated phosphatides has been to establish beyond doubt that the phospholipases *A* of snake or bee venoms only release the fatty acid from the β position

Combining biochemical and biophysical techniques, Dr A D Bangham and Dr R M C Dawson presented substantial evidence to suggest that the activation of at least two phospholipases is controlled by the electrokinetic properties of the lipid/water interface The ζ potential of lecithin suspensions was varied either by adding insoluble amphipathic molecules, for example, docosanyl pyridinium bromide or dicetyl phosphoric acid to the lecithin or by the addition of multivalent ions, for example, calcium ions or ferricyanide ions, to the bulk aqueous phase Such experiments showed that *Penicillium notatum* phospholipase requires micelles having a net negative (> 15 mV) ζ potential before hydrolysis of the lecithin occurred Calcium, uranyl and thorium ions, if present, as multivalent gegen ions, inhibited the system The phospholipase *C* (α toxin) of *Clostridium perfringens*, however, required a positively charged lipid interface and required either the addition of amphipathic cations to the lecithin, or divalent calcium or magnesium ions to the bulk aqueous phase That these interactions are confined to the lipid-water interface was demonstrated by following the hydrolysis of unimolecular films using lecithin highly labelled with phosphorus-32 The ability of phospholipase *C* (α toxin) to hydrolyse phosphatidyl ethanolamine, but only in the presence of lecithin, confirms earlier work and fits in well with the hypothesis that lecithin, being a surface-active zwitterion, can dilute the high net negative charge of a pure phosphatidyl ethanolamine micelle with ionically neutral molecules, thereby permitting the negatively charged enzyme to approach the micelle The adjustment of the net charge of lipids by admixture of lecithin may well be an important feature in a variety of biological systems, for example, blood coagulation, fat absorption Endorsing the importance of a definitive lipid/water interface for the activation of phospholipase *C*, van Deenan reported that synthetic phosphatidyl cholines prepared with C_2 or C_4 fatty acids were not hydrolysed and could not be shown to have any lamella structure in electron microscopic preparations

The present-day biophysical interest in phospholipids naturally centres around the structural arrangement of such molecules in various solvents—and in particular in water The accepted interpretation of the results obtained by X-ray diffraction, light scattering and with polarized light, is that most phospholipid mixtures consist of concentric layers of bimolecular leaflets intercalated with water The smallest repeating unit of mixed phospholipids in the presence of protein has recently been examined and the precise significance of the electron opaque lines of methacrylate embedded, osmium-fixed material discussed by Stoekenius, Schulman and Prince[5] Their evidence, together with that of Finean[6], strongly suggests that the smallest unit membrane recognizable in model lipid membranes is a bimolecular leaflet covered on both sides with protein—a structure postulated by Danielli nearly thirty years ago and recently presented by Robertson[7] as a structural entity in some biological cell components

Of particular interest to the biologist is the intermolecular arrangement of the phospholipids and sterols in the plane of any unit membrane or film Dr D G Dervichian and de Bernard[8] have already shown that in monolayer studies, lecithin forms molecular condensations with cholesterol, and Willmer[9] has recently indicated how such mixtures might give rise to a variety of mosaic patterns, conceivably controlling the permeability of membranes or in facilitating the absorption of specific proteins (for example, gonadotrophin)

The precise orientation of the ionic groups of the phospholipid is at present a matter of some controversy, but the concensus of opinion is that with pure phospholipids the charged groups lie in a nearly level plane at the water interface Finean[10], however, has presented evidence that cholesterol might realign the base of a phospholipid away from the water, in so doing, local areas of phospholipid surfaces might present net negative ζ potentials

As it is now possible to prepare large quantities of chemically pure, although inhomogeneous in fatty acid, lecithin, this substance has been studied extensively in terms of its conductivity, viscosity and micelle formation Drs P H Elworthy and D S McIntosh, examining the light scattering of lecithin, found that the micellar weights increased as the polarity of the solvent decreased They also concluded that in their series of solvents—ethanol, *n*-butanol and *n*-hexanol—the polar groups were probably hidden, while the hydrocarbon chains protruded outwards into the solvent This result is of great interest when it is remembered that lecithin exists as very large micelles in water and with the polar groups outwards.

The behaviour of fairly concentrated sols of lecithins in water with salt solutions has formed the basis of a study by Dr L Saunders and was reported to the meeting He finds that a film of some measurable mechanical strength forms at the sol/salt interface and that this film has some of the permeability characteristics of cell membranes Presumably the intermicellar channels restrict the diffusion of divalent and, to a lesser extent, monovalent ions

Finally, it must be remembered that phospholipids and sulpholipids are integral parts of living cells and as such are in dynamic equilibrium with metabolic and structural processes Isotope incorporation studies have repeatedly shown that certain phosphatides can exhibit high rates of turnover in cells undertaking active secretive or ingestive functions[11] L E Hokin and M R Hokin, for example, reported how the salt gland of certain marine birds rapidly incorporated phosphorus-32 when the gland was stimulated with acetyl choline—the normal physiological stimulus Their evidence is suggestive that in this instance sodium transport is coupled to the renewal of phosphate in phosphatidic acid, a process which appears to be catalysed by the cyclic action of diglyceride kinase and phosphatidic acid phosphatase. The questions raised during the course of this meeting suggest that it would be foolish to expect a complete understanding of the function of phospholipids even within the next thirty years A. BUILDING RESEARCH

THE annual report for 1960 of the Building Research Board of the Department of Scientific and Industrial Research (Pp 99 H M S.O, London. 7*s* 0*d*) is written and illustrated with the clarity which has characterized previous reports, and provides a convenient summary of the very diverse activities of the Building Research Station

Before a new building material can be used with confidence, information is needed on many aspects of its behaviour over long periods of time, and the devising of suitable accelerated tests is a major problem in this field of research The present report describes such a test for the weathering of polyester roofing sheets reinforced with glass fibre Work is in progress on the behaviour of rain-water goods made from various plastics; the chief problem here appears to be lack of colour stability

Another group of materials, lightweight aggregates for structural concrete, poses many problems including mix design, bond strength, moisture movement, and corrosion of reinforcement

Work in this field, begun in 1957, is still in progress, and aims to provide the basis for a future code of practice

Like most similar organizations, the Building Research Station is often asked to solve a problem within a few months Their experience has shown that "superficial short-term examination of problems is apt not to be rewarding". Unhappily, the converse is not always true, and one feels sympathy for the workers on stone preservatives who report, after five years investigation, that "no 'stone preservative' treatment has yet served its purpose well enough to merit commendation Some have done more harm than good . . nothing of proven value has emerged . . ".

Another important group of investigations is concerned with the economics of building construction and maintenance A survey of 1,000 post-war houses in Scotland has shown that certain non-traditional forms of construction lead to abnormally high maintenance costs, especially in conditions of severe exposure Prefabricated systems have a tendency to leave small quantities of work to be completed by traditional methods, at disproportionately high cost

The structural designer will be interested in the development of realistic design methods based on more comprehensive data than those now available New surveys of actual floor loads and snow loads on buildings are now in hand, and the problems of wind loading on tall buildings are also receiving attention

An important study of composite action in buildings is in progress Attention to the interaction of beams and slabs, and of walls and structural frames can make more difference to frame design than can the most elaborate frame analysis

The Building Research Station pioneered soil mechanics research in Great Britain, and is continuing the investigation of pile foundations. It would appear from results quoted in this report that the ability of deep cylinder foundations to carry load by both shaft friction and base reaction is still in some doubt

This important conclusion appears to be based on a limited series of tests on a laboratory model, and it would be a great help to readers if statements of this nature were accompanied by references to the list of publications at the end of the report At present it is not at all easy to relate the conclusions reported to the publications giving details of the original work.

The contents of the present annual report cover a very wide field, and this arbitrary selection of topics can do little more than indicate the diversity of matters treated No mention has been made, for example, of the interesting work on the equatorial comfort index for tropical buildings, or the effect of various construction methods on the earth pressures on buried service pipes In both cases an attempt is being made to replace the present trial-and-error approach by a logical theory developed from observed facts

This report should be of interest to all who design buildings or organize their construction.

R PAUL JOHNSON

INDUSTRIAL RESEARCH AND DEVELOPMENT IN THE UNITED STATES

TO obtain information about the economic resources allocated to research and development activities, the National Science Foundation of America has been conducting comprehensive surveys of research and development in the economy on a periodic basis Such surveys yield economic data that assist the National Science Foundation, the Federal Government, and other public and private organizations to assess the present research and development efforts and to formulate science programmes for the future

A report* summarizes the results of the 1958 survey of industrial research and development, the survey representing a continuation of the Foundation's series of annual surveys of research and development in industry that began in 1953.

---

* National Science Foundation, Washington Surveys of Science Resources Series, NSF 61-32 Funds for Research and Development in Industry, 1958 Pp xvi+119 (Washington, D.C Government Printing Office, 1961) 65 cents.

Funds for research and development performance in the industrial sector of the economy totalled 8·2 billion dollars in 1958. More than half this total was for research and development performed in the aircraft and parts, electrical equipment and communication industries, which were heavily engaged in Federally financed research and development.

The amount spent on industrial research and development in 1958 was 7 per cent higher than the 7·7 billion dollars total for 1957. Increases occurred between 1957 and 1958 in all industries for which separate data were obtained except aircraft and parts and rubber products. The relative increase in research and development of companies with less than 5,000 employees (15 per cent) exceeded that of companies with 5,000 or more employees (6 per cent) between 1957 and 1958.

More than half (56 per cent) the industrial research and development performance was financed by the Federal Government. Industries with the highest proportions of federally financed research and development performance were aircraft and parts (85 per cent) and electrical equipment and communications (68 per cent).

In contrast to the large Federal research and development financing in certain industries, 90 per cent or more of the total funds for research and development performance were from company funds in the following industries: food and kindred products, paper and allied products, drugs and medicines, other chemicals, stone, clay and glass products, primary ferrous products, and petroleum refining and extraction. The chemical and allied products industry exceeded all others in the dollar volume of company financed research and development.

Companies with 5,000 or more employees accounted for 84 per cent of the funds for performance of industrial research and development, compared with 7 per cent in companies with less than 1,000 employees and 9 per cent in companies with 1,000–4,999 workers.

An estimated number of 11,800 industrial firms carried out research and development in 1958, including 10,300 manufacturing companies and 1,500 non-manufacturing companies. In terms of research and development moneys, however, manufacturing companies accounted for 98 per cent of the total. Funds for research and development in 1958 were distributed by the character of work as follows: basic research, 4 per cent, applied research, 23 per cent and development, 73 per cent. Approximately three-fifths of the 295 million dollars for basic research was expended in the physical and mathematical sciences, about one-fifth in the engineering sciences, and the remainder in the life and other sciences.

The product fields of guided missiles, communication equipment, and aircraft and parts accounted for more than half the 7·9 billion dollars utilized for applied research and development. Although the companies in the aircraft and parts, and electrical equipment and communication industries accounted for most of this, companies in other industries also performed substantial amounts of applied research and development in these product fields.

The dollar volume of research and development performance per research and development scientist and engineer in 1958 was 32,900 dollars for all industries combined. Among major industry groups the average ranged from 16,400 dollars in food and kindred products to 52,500 dollars in motor vehicles and other transportation equipment.

Funds for industrial research and development comprised 3·8 per cent of net sales in manufacturing companies performing research and development. Total performance includes federally financed research and development, which amounted to 56 per cent of the total amount for 1958. Research and development performance funds as percentages of net sales were highest in the following separately reported industries: aircraft and parts (17·7 per cent), electrical equipment and communication (10·5 per cent), and scientific and mechanical measuring instruments (9·9 per cent).

STRUCTURE OF ALPHA-KERATIN

By PROF. S. KRIMM

Harrison M. Randall Laboratory of Physics, University of Michigan, Ann Arbor, Michigan

THE structure of α-keratin[1] has been assumed to be based on the α-helix[2] following the demonstration[3,4] that the coiling of such helices, possibly arising from periodic axial distortions[5,6], can account for the presence of the 5·15 Å. and 1·5 Å. meridian reflexions in the X-ray diffraction pattern. In particular, a three-stranded rope[6] seemed to account satisfactorily for the main features of the diffraction pattern[3,4]. Recent work[7], however, indicates that this structure may not be entirely satisfactory in explaining the details of the pattern, and other models involving additional layers of helices have been suggested[8]. The present ideas do not satisfactorily account for the changes in the X-ray pattern resulting from treatment with heavy metals[9,10], nor for some of the longitudinal regularities found in the matrix component of α-keratin by electron microscopy[10].

It is the purpose of this article to explore a possibility which has not been considered before and which seems to have merit in accounting for much of the data. Specifically, it is proposed that in the two-phase structure of α-keratin consisting of microfibrils and matrix, the latter, far from being amorphous or disorganized, consists of a relatively highly organized structure. In particular, whereas the microfibrils, as is known, compose the α-helical component, it is suggested that the matrix is built up of a structure similar to that of feather keratin, and that this matrix structure accounts for the 198 Å. fibre period[11,12] and the various orders of it which are observed and which are intensified by heavy-metal treatment.

In considering the evidence which suggests this proposal, it may first be noted that the characteristic α-keratin spacings at 5·15 Å. and 1·5 Å. may not, and indeed need not, be correlated with the 198 Å. repeat. Although accurate diffractometer measurements[13,14] give the former spacing as 5·18 Å., which would be a reasonable 38th order of 197 Å., it is not required that this be true in order to account for this spacing Secondly, the many orders of 198 Å which can be observed[11] bear a striking resemblance to the orders of the 189 Å repeat observed in the diffraction pattern of feather keratin[15], a fibrous protein which contains no α-helix component Thirdly, the uptake of metals occurs primarily in the matrix, which is rich in cystine compared to the microfibrils[16] Since this treatment affects primarily the low orders of the 198 Å meridional repeat[10] (the effect on the low-angle equatorial spots is also accounted for by penetration of the matrix by the reagent[9]), it is not unreasonable to suppose that the component giving rise to this long repeat is distinct from the α-helical component located in the microfibrils

The correlation of the matrix component of α-keratin with a feather keratin type of structure is suggested by the results of recent work on the structure of the latter fibrous protein[15,17] These investigations indicate that a structure which is in reasonably good agreement with the data can be developed from the hypothesis that proline residues are distributed periodically along an essentially extended polypeptide chain Amino-acid analyses, and the presence of a strong 8th order of the 189 Å fibre axis repeat, are consistent with the proposal that in feather every 8th amino-acid along the chain is proline[17]. The 198 Å fibre axis repeat of α-keratin (which although slightly larger than that of feather keratin is nevertheless consistent with similar values found for other proteins giving the feather keratin pattern, cf 197 5 Å for *Varanus* claw[18]) also is characterized by a strong 8th order reflexion[12] Chemical analyses[19–21] have indicated that the matrix component of high cystine content is that which is high in proline The proline content found[21] is of the same order as that found in feather[22], and at the present state of the analysis it can be said that they could indeed be equal The chemical composition therefore is entirely consistent with the presence in the matrix of the proposed type of extended chain structure It should be noted that infra-red spectra of α-keratins indicate the presence of a β-component oriented with respect to the fibre axis[23,24]

If we accept this possibility, then we find further that the proposed feather keratin structure[17] can account for several other of the dimensional features of α-keratin Thus, the predominantly observed fibre axis repeat in feather is expected to be half of 189 Å (ref 17), and this fits in well with the approximate 95 Å longitudinal periodicity seen in electron micrographs of the matrix of α-keratin[10]. Again, the diameter of the predicted fibrillar unit for feather keratin is about 22 Å (ref 17) Electron micrographs of wool[16] show that in the paracortex there are microfibrils of diameter about 60 Å the centre to centre separation of which is about 83 Å. These dimensions are consistent with each microfibril being separated from its neighbour (in an essentially hexagonal array) by one feather keratin unit Twelve feather keratin units will just pack around one microfibril Finally, the observation[25] that hydration of dry α-keratin results in preferential swelling of the matrix in comparison with the microfibrils may be understandable in terms of the open type of structure suggested for feather keratin[17].

The above proposal of two structural components in α-keratin can also help to explain the results of heavy-metal treatments Recent investigations of this kind[26] suggest that cystine is periodically located along the polypeptide chain of feather keratin (with a periodicity of about 47·3 Å) The same may be true for α-keratin Amino-acid analyses[21] show that the matrix of α-keratin has about twice as much cystine as does feather. If these residues were periodically located along the chain, we would expect heavy-metal treatment to enhance in all cases the 8th order of the 198-Å fibre axis repeat This is precisely what is found[9,10] This evidence itself suggests that the matrix component of α-keratin may be a relatively highly organized structure

There is another important characteristic of α-keratin which could be accounted for by the proposed model Recent work on the α → β transformation in keratin[27–29] has indicated the complex nature of this process and the likelihood that a simple transformation of a single chain from α-helix to β-extended chain is not involved Suggestions have been made that the transformation may proceed through an intermediate phase[27,28], or that there may be two crystalline phases[29,30] The foregoing model would fit in with the latter scheme, extension of the microfibrils leading to loss of the α pattern whereas further extension of the (already nearly extended) matrix component would result in the development of the β pattern The detailed mechanics of this process (which may, for example, involve the relative sliding of the two components with respect to each other) perhaps cannot be specified at this point, but the general mechanism does not seem to be eliminated by the available data

In summary, it is suggested that the matrix component of the two-phase structure of α-keratin consists of a relatively ordered polypeptide chain structure basically similar to that of feather keratin, and with which is associated the long axial periodicities in the X-ray diffraction pattern

Support for this investigation is gratefully acknowledged from U S Public Health Service grant *A*–2830

CRYSTAL STRUCTURES OF SALTS OF METHYLATED PURINES AND PYRIMIDINES

By R. F. BRYAN and K. TOMITA

Department of Biology, Massachusetts Institute of Technology, Cambridge, 39

NUMEROUS patterns of hydrogen bonding have been postulated between purines and pyrimidines in the various models which have been proposed for the structures of nucleic acids and their synthetic analogues. It is a disadvantage of the method of fibre crystallography, which is most directly applicable to the study of such structures, that it does not allow a refinement of the structural parameters based solely on the diffraction data, and hence it is important that structures proposed to explain fibre diffraction diagrams should be both chemically and stereochemically acceptable as well as in reasonable agreement with the diffraction evidence[1]. An examination, by X-ray diffraction techniques, of single crystals of salts of methylated purines and pyrimidines (the simplest analogues of nucleotides) might be expected to yield three valuable pieces of information which would be of use in the formulation of structures for nucleic acids, first, a knowledge of the molecular geometry of the various bases; secondly, an identification of the sites of protonation of the bases at acid *p*H; thirdly, a possible model for the geometry of inter-base hydrogen bonding in polynucleotides. With this in mind, we are conducting a systematic survey of acid salts of such methylated purines and pyrimidines and wish to report some of the results of work on two of these, 9-methyladenine dihydrobromide and 1-methylcytosine hydrobromide.

Crystals of 9-methyladenine 2-hydrogen bromide are orthorhombic with $a = 17.59 \pm 0.05$ Å, $b = 4.88 \pm 0.02$ Å., and $c = 11.75 \pm 0.04$ Å. The space group is $Pna2_1$ with four molecules of the dihydrobromide in the unit cell. The crystal structure was determined, using the heavy atom method, from examination of the (010) and (001) projections and refined, using Fourier and difference Fourier syntheses. In addition, the $(h0l)$ data were further refined by least squares methods. Fig. 1 shows the electron density distribution $\rho(x,z)$. Each molecule of methyladenine is enclosed by a three-dimensional network of Br$^-$ ions, the Br$^-$ . . . Br$^-$ contacts ranging in length from 4.25 to 5.17 Å.

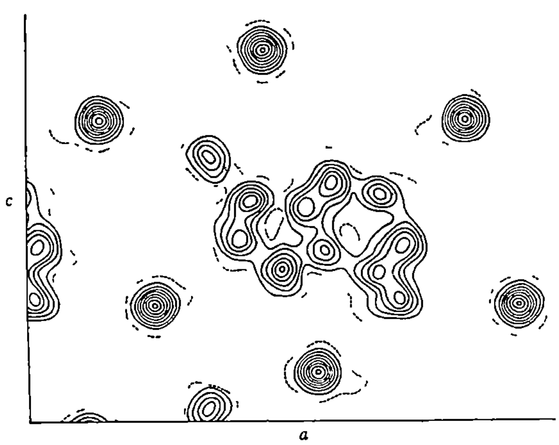

Fig. 1. Electron density $\rho(x,z)$ for 9-methyladenine 2-hydrogen bromide. Contours at equal but arbitrary intervals, intervals for Br$^-$ × 5

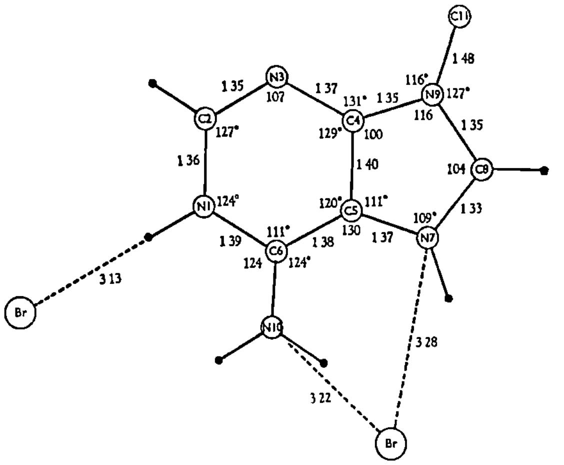

Fig. 2. Interatomic distances and angles for 9-methyladenine 2-hydrogen bromide

The conventional residuals, R, excluding unobserved reflexions, are 0.07 for $(h0l)$ and 0.11 for $(hk0)$. Despite these low values the overall accuracy of the structure determination is only fair, the standard deviation in the position ascribed to carbon or nitrogen atoms being about 0.05 Å., and the good agreement between observed and calculated structure factors may be attributed mainly to the very accurate location of the two bromine ions. The details of the molecular geometry are shown in Fig. 2. Although the dimensions found for the cation of 9-methyladenine are reasonable, no useful comparison can be made between them and the dimensions found by Cochran[2] for the adenine molecule in adenine hydrochloride, nor with those proposed by Pauling[3] or by Spencer[4] for the adenine molecule as it is assumed to exist in nucleic acids. This illustrates the disadvantage of using compounds containing such heavy atoms where particularly accurate molecular dimensions are sought. From our point of view, however, the most interesting feature of the structure is the hydrogen bonding pattern. There are no hydrogen bonds joining the purine molecules directly, each molecule forming instead three hydrogen bonds to neighbouring Br$^-$ ions. This is most probably because access to the only remaining acceptor atom on the adenine molecule, N(3), is hindered by the 9-methyl group. It is likely, indeed, that because of a similar effect exercised by the sugar molecules, no structures involving N(3) as an acceptor atom in hydrogen bond formation can occur in multi-stranded polynucleotide structures. The hydrogen bonds which are formed are N(1)—H ..Br(1), 3 13 Å ; N(10)—H. Br(2), 3 21 Å , and N(7)—H Br(2), 3 28 Å All these bonds are shorter than the more usual length found, 3 4 Å., at least two of them by significant amounts, and we postulate a strong electrostatic contribution to the bond energies All other intermolecular contacts are of normal lengths

The fact that the protonated nitrogen atoms are N(1) and N(7) provides additional evidence for the correctness of the structure proposed by Rich, Davies, Crick and Watson[1] for polyadenylic acid. Fibres of this substance show poor orientation at neutral *p*H, but a high degree of orientation when the *p*H is lowered somewhat At still lower *p*H, however, the orientation again disappears, though the molecular weight remains unchanged. Following Cochran[2], Rich *et al.* assume protonation of the adenine at N(1) with a consequent internal neutralization of the overall charge of the molecule The two strands of the helical molecule are assumed to be held together by pairs of hydrogen bonds between the 6-amino group and N(7) The disappearance of orientation at the very low *p*H can thus readily be explained as due to the disruption of this hydrogen bonding consequent on protonation of N(7)

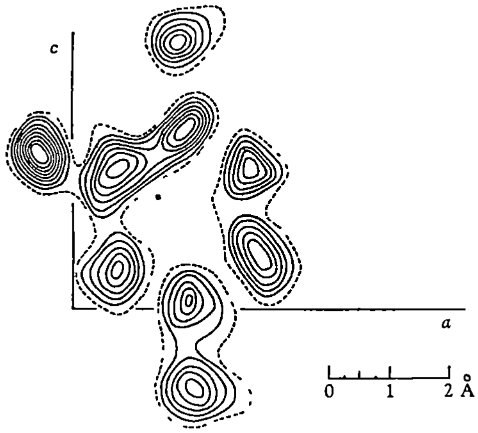

Fig 3 Electron density $\rho(x,z)$ for 1-methylcytosine hydrogen bromide The contribution of the Br$^-$ ion has been subtracted from the structure factors, its position is indicated by the dot

1-Methylcytosine hydrogen bromide also occurs as orthorhombic crystals with a = 12·98 ± 0 03 Å., b = 6 80 ± 0·02 Å , and c = 8 83 ± 0 02 Å. The space group is *Pnma* with four molecules in the unit cell which. in consequence, occupy the mirror planes of symmetry at $y = \frac{1}{4}$ and $\frac{3}{4}$ The structure was solved from the (010) projection by making use of the heavy-atom method The molecular arrangement is somewhat unusual and this caused us some initial difficulty in deciding on a correct trial structure. In projection, a Br$^-$ ion at $y = \frac{1}{4}$ is situated roughly in the centre of a cytosine ring at $y = \frac{3}{4}$. Fig. 3 shows a synthesis of the type $(F_0 - F_{\mathrm{Br}})$ giving the electron density $\rho(x,z)$ with the contribution of the Br$^-$ ion removed. This sandwiching of the bromine ions between the heterocyclic rings leads to a very efficient type of interlayer packing A similar arrangement is found in the case of 9-methylguanine dihydrobromide (work still in progress)

The structure was refined by means of difference Fourier syntheses to a value for the index R of 0 12 for ($h0l$) Structure factors were also calculated, as a check, for ($h1l$) and ($h2l$), giving the same value of

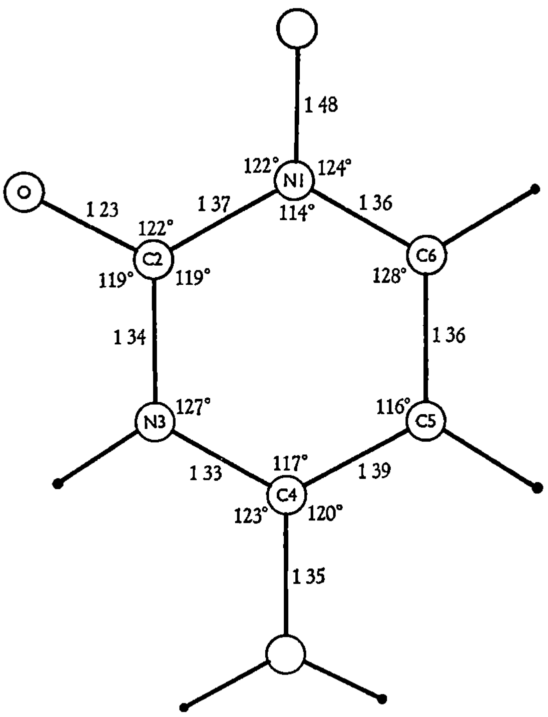

Fig 4 Bond-lengths and angles in the cation of 1-methylcytosine

R as for ($h0l$) in each case. Fig 4 shows the molecular dimensions found for the cation of 1-methylcytosine. The bond-lengths found (σC—C = 0 03 Å) are in good agreement with those suggested by Pauling[3] and by Spencer[4] for the cytosine molecule as it is assumed to occur in nucleic acids The sum of the individual differences in bond-lengths between our dimensions and those of Pauling is 0 10 Å., and for the Spencer model this sum is 0·08 Å. However, some of the bond-angles which we find are in marked disagreement with those suggested by either Pauling or Spencer The average difference is 6°, the maximum difference is 10°. We estimate[5] our standard deviation in bond-angle to be about 2°, and so these differences would seem to be significant in some cases.

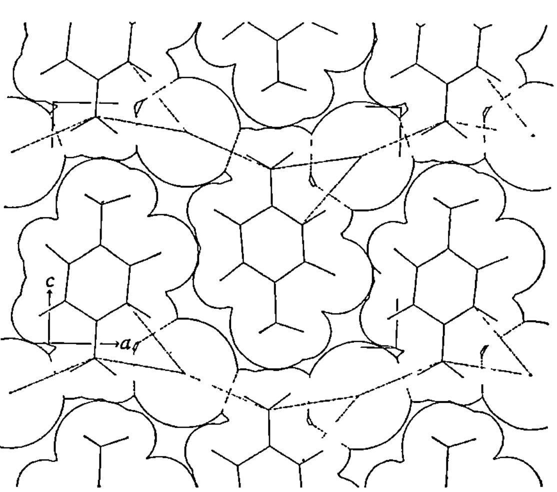

Fig 5 Packing drawing of the arrangement of molecules within a layer of the structure of 1-methylcytosine hydrogen bromide Conventional van der Waals radii are inscribed, hydrogen bonds are indicated by the lines

However, owing to the overlap, in projection, between the Br^- ion and the cytosine ring it is possible that the errors in the positions of some of the atoms in our structure are in excess of our estimate which is based on the assumption of non-overlapping atoms. We are therefore not prepared to offer our values for these angles as being intrinsically better than those in either of the two models with which we compare them. A subsequent three-dimensional refinement may enable us to improve the accuracy of this determination.

The cytosine ring is protonated at N(3) and there are again no hydrogen bonds between individual base molecules. Instead, each ring forms three hydrogen bonds of length 3·36, 3·39 and 3·40 Å to adjacent Br^- ions as illustrated in Fig. 5, which also shows the molecular packing within a given layer. Since the molecules are planar it is possible to inscribe the conventional van der Waals radii of the atoms, and this has been done in Fig. 5. It is seen that the packing is extremely efficient with the molecules forming an interlocking double dovetail arrangement, the backbone of the individual dovetail units being the hydrogen bonds. Particularly noteworthy is the manner in which the Br^- ion lies between N(3) and the 4-amino group and thus takes part in two hydrogen bonds. The deviation from linearity in each of these bonds is in excess of 25° and illustrates the large distortions which can be tolerated in such bonds where there is a compensating electrostatic interaction.

INTERACTION OF LIGHT AND ATMOSPHERIC PHOTOCHEMICAL PRODUCTS ('SMOG') WITHIN PLANTS

By O. C. TAYLOR, W. M. DUGGER, jun., E. A. CARDIFF and E. F. DARLEY

Departments of Horticulture, Agricultural Air-Research and Plant Pathology,
University of California, Riverside

DAMAGE to plants from ozone and peroxyacetyl nitrate, two photochemically formed components of 'smog', has been described[1-3]. However, variations in symptom expression and the degree of damage caused by a given concentration of these components, whether of synthetic or natural origin, have complicated development of an adequate biological assay method for these materials. These observed variations in symptomatology have implicated stomatal action, inorganic nutrition, temperature, genetics, ascorbic acid content, physiological age of tissue and photoperiod[4-8]. Plants grown under artificial illumination differ in their response to the photochemically formed pollutants as compared with plants grown in the greenhouse. Interactions between light and oxidants from the polluted atmosphere within plants, as reported here, might well explain some of the variabilities in symptomatology observed in earlier controlled experiments as well as the unexplained natural variability observed in the Los Angeles area. The results presented also emphasize the importance of standardizing plant growth conditions for future work of this nature.

Lots of pinto bean (*Phaseolus vulgaris*) and petunia (*Petunia hydrida*, var. Rosy Morn) plants were grown under the following light conditions: (1) natural light received in the greenhouse during August–November, (2) a 15-hr. photoperiod of 8·6 Klux from cool white fluorescent lamps in a shaded greenhouse and (3) a 15-hr. photoperiod of 21·5 Klux from Sylvania 'very high output (VHO)' fluorescent lamps also in the shaded greenhouse. Approximately 85° F. day and 70° F. night temperatures were maintained. Plants were exposed to the oxidants in chambers placed under a 21·5 Klux fluorescent lamp panel. Dark chambers in the greenhouse were used for the experimental dark conditions. The greenhouses and fumigation chambers were supplied with carbon filtered air[9] to remove the naturally occurring oxidants.

To ensure that the stomates were open at the time of exposure to the oxidants, all plants pre-conditioned by a dark period were given 15–30 min. light before exposure to the oxidants. Stomatal opening was determined by a resistance porometer[10] with a leaf-cup attached to a snap spring device to ensure a rapid seal to the leaf. In later experiments the porometer measurements were supplemented with transpiration measurements. During the 15–20 min. before exposing the plants to the oxidants the rate of water-loss by transpiration was followed. When this rate of water-loss equalled the rate of water-loss from the pre-light treated plants the fumigation was started.

Plants were exposed to the oxidants for periods of 30 min. or less. After exposure, unless otherwise specified, the plants were returned to the pre-treatment light condition. Symptoms of oxidant damage were usually apparent within 4 hr.; however, assay of damage was made 48 hr. after exposure to the oxidants. The extent of damage was expressed as the percentage of leaf area showing symptoms of the oxidant injury. Eight to twelve plants were used in each treatment and the experiments were repeated several times.

The type and extent of ozone and peroxyacetyl nitrate injury on bean and petunia plants were affected by light intensity under which the plants were grown before treatment. Sensitivity to ozone injury was increased by the low light intensity (8·5 Klux), while sensitivity to peroxyacetyl nitrate was increased by the higher light intensity (21·5 Klux). A total bleaching and collapse of affected leaf tissue characterized the oxidant injury on plants grown under the low light intensity. By contrast, oxidant injury on plants grown in the higher light intensity usually appeared as bronzing of the lower leaf surface, and ozone injury on the bean appeared as discrete dark brown spots on the upper leaf surface.

Sensitivity of pinto bean and petunia plants to peroxyacetyl nitrate was significantly affected by the presence of light immediately before, during or after exposure to the toxicants. A 24-hr. pre-treatment dark period completely protected these plants against peroxyacetyl nitrate damage (Fig. 1 *DL*) regardless of subsequent light régime during and after fumigation. Plants which had received the standard 15-hr. day, with a 5- to 6-hr. light period immediately preceding the fumigation, were severely damaged (Fig. 1, *L*), whereas similar plants transferred to the dark for 24 hr. after fumigation were uninjured (Fig. 1, *LD*). Bean plants returned to the light after the 24-hr. post-dark period appeared normal and did not develop oxidant damage, whereas some oxidant damage did develop on the petunia plants after transfer to the light.

In another series of experiments, bean plants were fumigated with very high concentrations (5 p.p.m.) of peroxyacetyl nitrate for 10 min. All the plants were grown under the 15-hr. light régime and were returned to the lights after the 10-min. fumigation. Darkness during this short fumigation period gave complete protection from damage to petunia and bean plants while identical plants fumigated similarly in the light were severely damaged (Fig. 2). Porometer measurements showed that during the 10-min. dark period the resistance to air-flow through the stomates decreased only 0·028 unit[10], an insignificant change. This indicated that the observed results were related to the interaction of light and some product in the plant and not to the exclusion of peroxyacetyl nitrate by closed stomates.

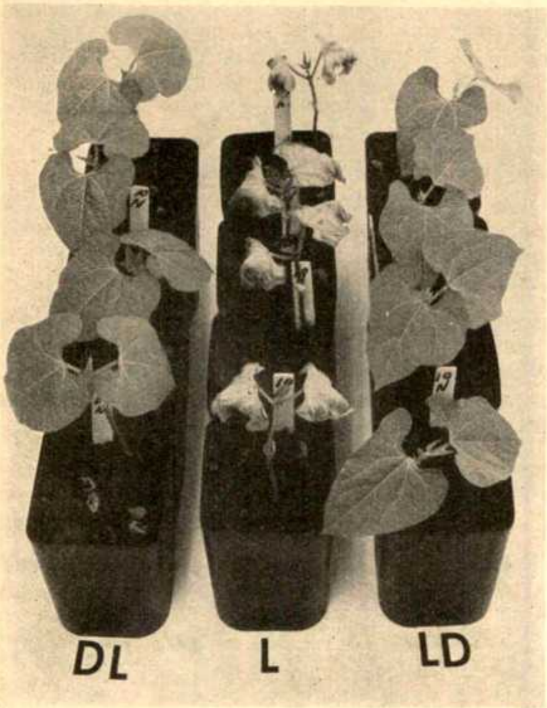

Fig. 1. Pinto bean plants fumigated for 30 min. with 1·0 p.p.m. of peroxyacetyl nitrate
DL, dark before (24 hr.), light during and after fumigation—no damage; *L*, light before (6 hr.), during and after fumigation—severe damage; *LD*, light before and during fumigation and dark (24 hr.) after fumigation—no damage

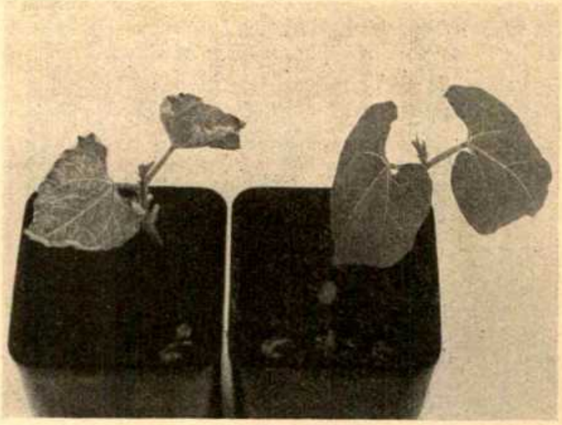

Fig. 2. Ten-day-old pinto bean plants exposed to 5 p.p.m. peroxyacetyl nitrate for 10 min. Left, light before, during and after fumigation—severe damage. Right, light before, dark during (10 min.) and light after fumigation—undamaged

The interaction of light and ozone was unlike that of light and peroxyacetyl nitrate. A considerably longer pre-treatment of dark period (48 hr. or longer) was necessary to provide protection to petunia and bean plants from an ozone fumigation (Table 1). The marked reduction in extent of ozone damage that occurred as the pretreatment dark period was lengthened beyond 24 hr. suggests that susceptibility may be dependent on the level of photosynthate or some carbohydrate intermediate within the tissue. Further evidence of the difference in action of peroxyacetyl nitrate and ozone was shown by the damage response obtained with a short, dark period during fumigation and with 24-hr. post-dark treatment. Both these conditions prevent oxidant injury from peroxyacetyl nitrate but have no effect on ozone damage. There were indications from additional experiments that under the conditions of these experiments the bean required at least 3–4 hr. of light after fumigation for symptoms of damage by peroxyacetyl nitrate to develop.

The distinct interrelationship of light with the oxidizing air pollutants in plants definitely shows that there is a photochemical reaction between the oxidant and some intermediate synthesized by light in the plant. The reactions of this intermediate with the oxidant peroxyacetyl nitrate is further dependent on light to cause a change in the metabolism of the plant sufficient to induce irreversible leaf damage.

Table 1. EFFECT OF VARIED LENGTHS OF DARK TREATMENTS BEFORE, DURING AND AFTER FUMIGATION ON THE PERCENTAGE OF PINTO BEAN LEAF AREA INJURED BY OZONE AND PEROXYACETYL NITRATE (PAN)

Fumigant and concentration	Pre-dark period (hr.)*	Condition during fumigation	Condition after fumigation	Injury (per cent)†
Ozone, 0·6 p.p.m.	0	light	light	76
	24	,,	,,	77
	48	,,	,,	0
	0	,,	dark	80
PAN, 1·0 p.p.m.	0	,,	light	99
	24	,,	,,	0
	48	,,	,,	0
	0	,,	dark	0

* The pre-dark period started at 9 a.m. The plants were grown under fluorescent lamps of 21·5 Klux with a light period of 15 hr. (4.30 a.m.–7.30 p.m.). The plants were moved into the light at 9 a.m. and fumigation started after the stomates had opened (15–30 min.). A resistance porometer was used to determine when the stomates were open.

† Average values from 8–12 plants per treatment.

ACID-SOLUBLE NUCLEOTIDES OF *STAPHYLOCOCCUS AUREUS*: MASSIVE ACCUMULATION OF A DERIVATIVE OF CYTIDINE DIPHOSPHATE IN THE PRESENCE OF PENICILLIN

By Dr. J. J. SAUKKONEN

Biochemistry Laboratory, State Serum Institute, Helsinki

PENICILLIN is known to cause accumulation of three uridine nucleotides in *S. aureus*[1]. The compounds were identified by Park as uridine diphosphate (UDP)–acetylmuramic acid, its alanine derivative, and a nucleotide composed of a peptide (ala-glu-lys-ala-ala) and UDP–acetylmuramic acid[2]. Several aspects of nucleotide accumulation in the presence of penicillin or other anti-bacterial substances have been investigated extensively[3]. On the basis of their findings, Park and Strominger have suggested that penicillin might be a specific inhibitor of transfer of the peptide from the most complex of the above nucleotides to the cell wall structure[4]. Relatively little attention has been paid to other nucleotides present in penicillin-treated cells. Strominger has investigated the acid-soluble extract of penicillin-inhibited *S. aureus* by means of anion exchange chromatography[5]. In addition to the UDP-derivatives, cytidine-5′-monophosphate (CMP), adenosine-5′-monophosphate (AMP) and small amounts of unidentified ultra-violet-absorbing substances were detected. Penicillin was reported to cause a doubling in the amount of CMP, when compared with untreated cells. Park and Strominger have noted, according to a personal communication to Armstrong *et al.*[6], the accumulation of cytidine diphosphate (CDP)–ribitol in *S. aureus* during treatment with penicillin and crystal violet. A report of the accumulation of this nucleotide induced by crystal violet has been published[7]. In the course of another investigation, indications were found of the presence of a large number of nucleotides in *S. aureus*, prompting the present work.

S. aureus 209 Pfeiffer (obtained from Dr. I. Rantasalo of this Institute) was grown in a medium adapted from that of Park and Johnson[1], with shaking at 37° C. At approximately half maximal growth, penicillin (benzylpenicillin, the Distillers Co., Ltd., London) was added to a final concentration of 10 µgm./ml. culture medium. After incubation for 1 hr., the cells were gathered rapidly in a refrigerated centrifuge and frozen. The pellet was extracted with cold 0·6 *N* perchloric acid and the acid-soluble fraction was neutralized and chromatographed on a 'Dowex-2' column at 4° C., using the gradient elution system of Hurlbert *et al.*[8]. Details of the procedure have been described in ref. 9.

Typical elution diagrams of normally grown and penicillin-treated cells are presented in Fig. 1. In both cases, a number of ultra-violet-absorbing compounds can be detected. Fraction *A*, which represents a large portion of the total ultra-violet-absorbing material, contains several substances. Chromatography of this fraction in a system with better resolution revealed in addition to diphosphopyridine nucleotide and CMP a third major compound in the pencillin-treated bacteria. This compound appears to be a nucleotide giving a positive ninhydrin reaction. Fraction *B* was identified as AMP. Analysis of peak *C*, characterized by its high 275/260-ratio, will be given here. Derivatives of adenine, guanine, uracil and cytosine have been found in the subsequent fractions. Peaks *D* and *E* were shown to be uridine nucleotides containing amino-acids, and presumably correspond to the known derivatives of UDP (ref. 3).

When the two patterns of nucleotides are compared, a striking increase in the amount of fraction *C* is seen in the penicillin-treated cells. Material corresponding to this fraction was collected from several preparations and purified by means of paper chromatography in neutral ethanol – ammonium acetate – water[10]. The small amount of the compound recovered from repeated runs in this system was subjected to further analysis. The substance was found to be uniform in several other solvent systems. The mobilities were close to the values reported earlier[7,11] for CDP–ribitol (in propanol–ammonia–water: R_F 0·36, in neutral ethanol–ammonium acetate–water: R_{UMP} 1·23. The base, which was isolated by means of paper chromatography after vigorous acid hydrolysis[12], gave a typical spectrum of cytosine in 0·01 *N* hydrochloric acid and in 0·01 *N* sodium hydroxide. A colorimetric assay[13] yielded 1·88 moles of phosphorus/mole cytosine. Paper chromatography in propanol – ammonia – water[14] after acid hydrolysis yielded in addition to CMP and inorganic phosphorus other breakdown products, two of which gave a positive reaction for phosphoric esters[14] and with ammoniacal silver nitrate[15]. While it has not yet been possible to identify the phosphoric ester moiety with certainty, the evidence available suggests the compound to be identical with CDP–ribitol[11,16].

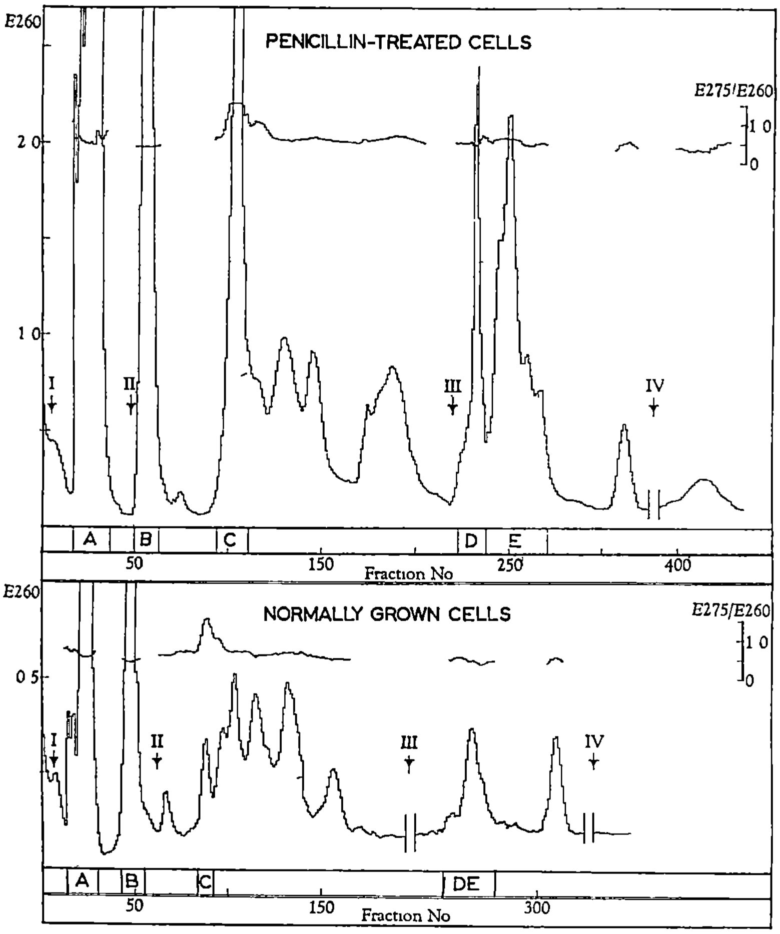

Fig. 1. Anion exchange chromatograms of extracts from penicillin-treated *S. aureus* and from normally grown cells. Bacteria from 4 l. of culture were extracted in both cases. The column was 'Dowex-2', $HCOO^-$, 200–400 mesh, 8 per cent cross-linked. A 1.0 × 18 cm column was used in the first case, a 1.2 × 15 cm column in the latter instance. The volumes of the mixing flasks were 450 and 375 ml., respectively. After washing with distilled water, the column was eluted with the following solutions in the reservoir: I, 0.5 *N* formic acid, II, 4 *N* formic acid, III, 4 *N* formic acid and 0.4 *N* ammonium formate, and IV, 4 *N* formic acid and 0.8 *N* ammonium formate, as indicated on the diagrams.

The present work shows that a large number of nucleotides is found both in penicillin-treated and in normally grown *S. aureus*, apparently forming a pattern similar to the distribution discovered in some other micro-organisms and in many animal tissues (cf. refs. 9 and 17). The various uridine nucleotides from the extracts of penicillin-treated bacteria have not yet been identified. It is assumed that they belong to the group of UDP-derivatives involved in cell wall synthesis. Ito *et al.* have reported that the UDP–acetylmuramic acid peptides of this strain contain aspartic acid and glycine[18]. The accumulation of uridine nucleotides is paralleled by the massive accumulation of the CDP-derivative, which in many cases surpasses the increase in the amount of individual uridine nucleotides.

The difference between the present results and earlier findings could be due to a number of factors. As pointed out by Strominger in the case of bacteria treated with crystal violet, the accumulation of CDP–ribitol cannot be demonstrated with all strains of *S. aureus*[7]. Possible differences in the composition of the culture medium and in other experimental conditions could also have influenced the results. Baddiley and Mathias, who originally discovered CDP–ribitol and CDP–glycerol in *L. arabinosus*[19], found the compounds very labile during extraction. This was attributed to the presence of potent phosphatases. For this reason, heat-killed bacteria have been used for later investigations. Strominger, who inactivated the enzymes by heating a washed bacterial suspension at 100° C for 10 min., found great variations in the amount of CDP–ribitol from crystal-violet-treated cells, accompanied by a corresponding change in the amount of CMP (ref. 7). In the work described here, the bacteria were grown in small batches, chilled rapidly and extracted at low temperature. Even a small delay in chilling was found to reduce the amount of the nucleotide considerably. With proper care, this method seems to give high yields of the nucleotide.

It has been suggested that CDP–ribitol might be a precursor of teichoic acid, a component of bacterial cell wall containing ribitol phosphate[6]. While the biology of the accumulation of CDP–ribitol is not well known, it is interesting to note that both penicillin and crystal violet cause accumulation of this nucleotide. These two agents appear to interfere at different points with the uridine nucleotide pathway leading to cell wall synthesis[7]. Whether the accumulation of CDP–ribitol is a result of an independent action of penicillin on the cytidine nucleotide metabolism or whether the accumulation of the two types of nucleotides is caused by an interference with a single reaction in the metabolic sequence, cannot yet be decided.

SENSORY DEPRIVATION AND FŒTAL CIRCULATORY HOMEOSTASIS

By PROF S R. M REYNOLDS

Department of Anatomy, University of Illinois, College of Medicine, Chicago, Illinois

EMBRYOLOGISTS seem to overlook the effect of a flotation-type of existence *in utero* on physiological activities within a fœtus as compared with physiological capabilities once development has proceeded through the period of morphogenesis Morphological differentiation must precede functional capability This is true of single-organ systems or of two or more interdependent systems such as homeostatic regulatory mechanisms However, full function of one or more completely developed secondary organ systems may not occur because a primary organ system essential to the secondary one is not yet called into action by the exigencies of the environment It is this sort of system–system interaction that appears to be involved in the circulatory adjustments of the fœtus (lamb) *in utero*

The problems of fœtal heart-rate, blood pressure and reflex mechanisms have been reviewed by Windle[1] and Barcroft[2] In 1954, when fœtal blood pressure and heart-rate were recorded *in utero* with the membranes intact[3], fœtal circulatory characteristics could be studied in nearly normal circumstances In such a preparation, responses to a variety of stressful situations were determined

Parasympathetic and sympathetic nervous system capabilities were explored, largely with the fœtus *in utero* Included were the responses of heart-rate and blood pressure to (*a*) increased intrauterine pressure[4], (*b*) graded degrees of hypoxia[5], (*c*) disturbances of the maternal circulation[6], (*d*) occlusion of the umbilical cord[7], (*e*) vagotomy[8], (*f*) stellate and thoracic ganglionectomy[8], (*g*) excision of the fœtal adrenal glands[8]

The resting fœtal heart-rate decreases when intrauterine pressure increases by a weight placed on the uterus and decreases when the weight is removed These are transient episodes evoked by a brief and dynamic stimulus The bradycardia is vagal in origin since it is abolished by atropine There is therefore, a competent vagal mechanism which is brought into temporary action by this change in the environment

A lamb *in utero* and its mother respond differently to the same asphyxial stimulus When nitrogen is given to a ewe, her heart-rate and blood pressure rise The fœtus shows bradycardia and no change in blood pressure When atropine is given to the fœtus during bradycardia the heart-rate becomes rapid The bradycardia is vagally induced Again we see that the autonomic system of the lamb responds to this stress by parasympathetic output and the fœtal response is unlike that of the adult

Less stressful stimuli have an effect also When a pregnant ewe is subjected to progressively stronger hypoxia, the fœtal heart-rate decreases or it shows a 2 1 heart block which is vagal in origin Similarly, if there are acute disturbances of the maternal circulation involving transient congestion of the maternal portion of the placenta, evanescent decreases in fœtal heart-rate occur This is the result of induced vagotonia

From these and other experiments we conclude that the parasympathetic system of the fœtal lamb is functionally competent, but it lacks a stimulus to maintain parasympathetic tone

Most of the present observations were made with ewes lightly anæsthetized with diallylethylabarbituric acid It might be argued that this anæsthetic abolishes existing vagal tone This is unlikely, however, since vagotonia is the easiest response in the lamb to exhibit under this anæsthesia and experiments made with the ewe operated under local anæsthesia ('Procaine') alone make no difference in the fœtal responses to stress or in the resting characteristics of the fœtal circulation

Barcroft found progressive vagotonia as a fœtal lamb becomes larger However, the *in utero* rates observed by him were recorded by auscultation and by palpation which involved some pressure on and handling of the uterus which, as we have shown, induces vagotonia From Barcroft's experiments on lambs at Cæsarean section, it appears that the acute response to stress of handling induces vagotonia, since he operated and observed very rapidly He says, "Let me emphasize again, that if the phenomena which have just been described [fœtal vagotonia] are to be observed they must be observed at once on the delivery of the fœtus—a delivery which must be carried through with no strain on the uterine and umbilical blood vessels and no exposure of the cord or fœtus—it may seem wasteful to do an experiment on a sheep which only takes 10 min and produces but a single lesion, but it is less wasteful than for him to misinform himself on 3 or 4 matters" (ref 2, p 137)

Concerning sympathetic activity in the fœtus, evidence is meagre but equally clear When normal resting fœtal heart-rates in lambs are compared with resting heart-rates after bilateral excision of the stellate and other thoracic sympathetic ganglia, no change occurs in resting fœtal heart-rate This is true whether the vagi are intact or sectioned or both carotid sinus areas are excluded from the circulation One must conclude that there is no appreciable resting sympathetic tone in the fœtus so far as heart-rate is concerned

One type of evidence has been obtained which resulted in sympathetic system activity in the fœtus With the heart completely denervated severe anoxia was produced by temporary occlusion of the umbilical cord The heart-rate showed a slow but profound decrease, due to myocardial depression On release of the cord, an extremely fast and prolonged tachycardia was seen The fœtus struggled, exhibited strong expiratory effort and passed meconium The experiment was repeated after incision of both fœtal adrenal glands After anoxia, the heart-rate returned to normal without tachycardia *In extremis*, therefore, there was mass stimulation of the sympathetic system

One must conclude that the sympathetic system of the lamb fœtus, like the parasympathetic system, is functionally competent but inactive in a resting fœtus One asks, therefore, why a developed and competent autonomic system is silent except in the face of transient and dynamic stresses

Examination of the development of cardiovascular responses in lambs soon after birth is crucial to the hypothesis suggested above A few observations have been made in lambs 4–12 days of age, averaging about 8 days Responses to the following stresses have been studied (*a*) carotid artery occlusion (6 lambs), (*b*) bilateral vagotomy (8 lambs), (*c*) severe hypoxia (9 lambs) The results are summarized in Tables 1, 2 and 3

Table 1 shows that carotid artery occlusion in lambs yields a rise in blood pressure like that of the adult, the heart-rate response is more or less intermediate between the adult and the fœtus

Table 1 COMPARISON OF THE EFFECT OF CAROTID ARTERY OCCLUSION IN FŒTUSES, LAMBS AND EWES

	Blood pressure (per cent)*			Heart-rate (per cent)*		
	+	○	–	+	○	–
Non-pregnant ewes (ref 10)	100	0	0	50	20	30
Lambs (ref 6)	100	0	0	33	0	67
Fœtuses (ref 5) (last third preg)	20	60	20	0	20	80

* Percentage of animals showing increase (+), no change (○) or decrease (–)

Table 2 shows that vagotomy in adult ewes and lambs causes a fall in blood pressure and a decrease in heart-rate while blood pressure in fœtuses is unchanged, although the decrease in heart-rate occurs The effect of vagotomy in the lamb parallels more closely the change in the adult than in the fœtus

Table 2 COMPARISON OF THE EFFECTS OF VAGOTOMY IN FŒTUSES, LAMBS AND EWES

	Blood pressure (mm Hg)		Heart-rate (b p m)	
	Before	After	Before	After
Non-pregnant ewes (ref 12)	101 5 (±8 9)/ 81 8 (±8 2)	87 3 (±8 5)/ 64 (±6 6)	110 4 (±8 5)	99 5 (±6 5)
Lambs (ref 6) (mean blood pressure)	85	70 5	234	194
Fœtuses (ref 5) (mean blood pressure)	37 9 (±4 4)	37 8 (±2 4)	166 7 (±13 7)	158 8 (±14 0)

Although there is a great variability of response in the effects of severe hypoxia in all three groups, Table 3 shows that the blood pressure of the fœtus was, with one exception, unaffected by acute hypoxia The responses in lambs and adults are rather similar The heart-rates were variable but once again the lambs and ewes resemble each other to the extent that some of each showed cardiac acceleration which was not seen in the fœtus

These results suggest that new-born lambs resemble adults in their responses to the three stresses employed More refined experiments are needed to establish this point, but the evidence seems clear that circulatory homeostasis begins soon after birth in the sheep

Table 3 COMPARISON OF EFFECTS OF HYPOXIA IN FŒTUSES, LAMBS AND EWES

	Blood pressure (per cent)			Heart-rate (per cent)		
	+	○	–	+	○	–
Ewes (ref 15)	33 4	46 6	13 4	46	46 6	13 4
Lambs (ref 8)	55 5	33 4	10 1	33 4	20 2	44 5
Fœtuses (ref 7) (last trimester)	0	86 7	13 4	0	42 8	57 2

Recent experiments on men given bed rest[9] or immersed in water for a day to a week[10] show that cardiovascular homeostasis depends on proprioceptive input to the central nervous system Following immersion there is a progressive decline in blood pressure, an increase in heart-rate, and a loss of the diurnal variation in heart-rate The response of heart-rate to the mild stress of a tilt table was much exaggerated An elevation of diastolic and a decrease of systolic blood pressure occurred, signifying diminishing cardiac output With more severe stress of exercise on a treadmill, the deficiency of homeostasis was more exaggerated In short, prolonged reduction of proprioceptive input by weightlessness leads to loss of effective homeostatic regulation in man and exaggerated sympathetic system output

The concept that homeostatic regulatory mechanisms depend on sensory input to the nervous system is nicely set forth in a recent book by Stanley-Jones[12] in which the roles of monitoring positive and negative feed-backs in a wide range of biological systems are reviewed Feed-backs acting on physiological mechanisms result in stabilization, consequently they prevent by negative feed-back a runaway to a maximum (for example, excessive sympathetic activity as in the deconditioned man[10])

Stanley-Jones distinguishes between two main types of sensory inputs (1) those in which brief reflex responses occur and are dynamic in the sense that they elicit reflexly a response of limited duration and a purposeful nature, and (2) those that serve to produce a sustained sensory input, activating the nervous system on a long, continuing basis The former are responses to quickly adapting sense organs, the latter, to slowly adapting sense organs. In the main, the second type have their origin in postural input nervous mechanisms from otoliths and from muscle spindles Speaking of antigravity feed-back in higher vertebrates he says "The new feature is the augumentor system It is Nature's response to the challenge of gravity It employs a positive refection (feed-back) to maintain the posture of the body when at rest, instead of the negative refection used in fishes The muscle spindle is the little machine inside the big machine". Speaking of weightless adults deprived of all sensory input, Stanley-Jones says "The physical status of adults in these circumstances resembles nothing so much as a return to the fœtal condition of isothermal floating in the amniotic fluid of the womb, it is not surprising therefore that the body regression to prenatal conditions should cause a similar regression on the mental plane" With respect to the latter reference, the reader should consult an editorial on the subject[13]

The fœtus *in utero*, like the immersed man in Graveline's experiment, is a free-floating organism As in that experiment, the fœtus is in a sort of zero-gravity situation so far as weight is concerned It is not called on to use its proprioceptive reflexes to offset the effect of gravity in order to maintain posture. The fœtus is subject to no unequal forces It lacks, therefore, the action of a monitoring feed-back from the environment Consequently there is a deficiency of autonomic nervous system controls when the fœtus is in a resting, unstressed situation It is as if the fœtal heart were like that in a heart-lung preparation, subject to its intrinsic controls on a chemical basis unless the autonomic system is called into play by sensory input from its environment The fœtus does possess from a time early in development the capacity for well-characterized patterns of behavioural (dynamic) responses, as Coghill[14] and Hooker[15] have shown, although Windle[1] is of a different opinion regarding their nature

After delivery in those species that are mature at birth antigravity input to the central nervous system is established rapidly It appears, therefore, that such sensory input to the central nervous system is an essential factor in contributing to sustained autonomic system output, at least so far as cardiovascular homeostasis is concerned. The effect is one of negative refection mediated by the parasympathetic system This problem is part of the larger one of sensory deprivation in general on the body.

How effective homeostasis will be after birth must vary with the degree of morphological maturity at birth Opossums, hamsters, mice, rats, rabbits, kittens, puppies, piglets, human babies and many other species will lack the capacity for homeostasis at birth because they do not respond to gravity. Others, such as guinea pigs, foals, lambs, calves, kids, and many other species will possess to a marked degree the capacity for effective homeostasis since they can stand, walk (or run) and regulate fairly well their body-temperature when they are born Most notably, they possess a capacity for proprioceptive input to the central nervous system when they are delivered from a condition of weightlessness during development

It is significant that the uterus is the original space capsule of mankind, and that all men have, so to speak, been in weightless orbit before they were born

TRANSAMINATION AND THE CONTROL OF MITOCHONDRIAL PATHWAYS

By DR. H. GUTFREUND, DR. K. E. EBNER* and MISS L. MENDIOLA

National Institute for Research in Dairying, Shinfield, Near Reading

RECENT work in several laboratories has demonstrated that the most important pathway for glutamate oxidation is via transamination and oxidation of α-oxoglutarate[1,2]

$$\begin{array}{c} \text{oxaloacetate} + \text{glutamate} \rightarrow \text{aspartate} + \alpha\text{-oxoglutarate} \\ \underline{\alpha\text{-oxoglutarate} + 1\tfrac{1}{2}\, O_2 \rightarrow \text{oxaloacetate} + CO_2} \\ \text{glutamate} + 1\tfrac{1}{2}\, O_2 \rightarrow \text{aspartate} + CO_2 \end{array}$$

Jones and Gutfreund[2] have shown in their detailed work on guinea pig liver and mammary gland mitochondria that under *in vitro* conditions liver mitochondria oxidize some glutamate via glutamic dehydrogenase, but that the above transaminase pathway is more important and the latter is probably the only pathway under physiological conditions. Mammary gland mitochondria have no detectable glutamic dehydrogenase activity[2,3] and yet they oxidize glutamate at approximately the same rate as liver mitochondria. These findings indicate that the concentrations, activities and specificities of mitochondrial transaminase are most important data for the analysis of the control of mitochondrial metabolism

We shall attempt to present a discussion of· (1) the concentrations of transaminase and other enzymes in various mitochondria, (2) the relation between transaminase concentration and the concentrations of pyridine nucleotide - linked enzymes in mitochondria, (3) some special aspects of the enzyme kinetics of transaminase; (4) the so-called latency of mitochondrial transaminase and its relation to the control of pathways in intact respiratory particles

The purpose behind a detailed examination of various enzyme systems in the pure isolated form and in intact respiring mitochondria is to differentiate between various possible factors which control the direction and intensity of multi-enzyme pathways from junction points A thorough knowledge of an isolated enzyme under various conditions and data on the behaviour of this enzyme in mitochondria should give information about the conditions and surroundings of this enzyme in respiratory particles To get a complete picture of chemical organization in mitochondria in this way is necessarily a long-term programme; but some of the investigations reported here are intended to illustrate this approach to the transaminases of mitochondria and their relation to the enzymes of the citric acid cycle More details of similar work on enzymes of the citric acid cycle are reported elsewhere[2,3].

Enzyme Concentrations in Mitochondria

Investigations on the concentrations of various active components of mitochondria from different tissues are too numerous to be referred to individually Bucher and Klingenberg[4] review data on enzyme and coenzyme concentrations, Birt and Bartley[5] discuss pyridine nucleotide movements in mitochondria, and Estabrook and Holowinsky[6] discuss the cytochrome content of various mitochondria The present investigation was carried out to provide data on the concentrations of a number of enzymes from assays on the same mitochondrial preparation, which has also been used for work on intact mitochondria as discussed below and elsewhere[3].

---

* Canadian National Research Council Post-doctoral Fellow

Table 1 contains results for the assay of activities of a number of mitochondrial enzymes at 25° under specified conditions All the assays were performed on samples of preparations of mitochondria which were first used intact for respiration experiments[3] Three samples of rat liver mitochondria were kindly provided by Dr. W N Aldridge. These samples were frozen at $-20°$ and just before use they were diluted ten times and aliquots of such disrupted mitochondria were added to appropriate reaction mixtures and the rates of the oxidation or reduction of NAD (nicotinamide–adenine–dinucleotide) or NADP (nicotinamide–adenine–dinucleotide–phosphate) were followed spectrophotometrically at 340 mμ The transaminase assays were coupled to dehydrogenases in the following manner

(1) aspartate + α-oxoglutarate $\rightarrow$ oxaloacetate + glutamate

the rate of oxaloacetate formation was determined by following the rate of oxidation of NADH (reduced nicotinamide–adenine–dinucleotide) in the presence of excess malic dehydrogenase In broken mitochondria the endogenous concentration of malic dehydrogenase was sufficient for this assay

(2) oxaloacetate + glutamate $\rightarrow$ aspartate + α-oxoglutarate

The rate of α-oxoglutarate formation was determined by following the rate of oxidation of NADPH (reduced nicotinamide–adenine–dinucleotide phosphate) in the presence of ammonia and excess glutamic dehydrogenase Glutamic dehydrogenase will oxidize NADPH at approximately half the rate of NADH, while the oxaloacetate reduction in broken mitochondria was completely specific for NADH

At this stage the data obtained for the activity of transaminase, glutamic dehydrogenase, isocitric dehydrogenase and malic dehydrogenase are mainly of comparative interest. To establish the absolute concentration of these enzymes one has to find out whether their possible latency—which is discussed later—has been completely overcome and whether there are any significant losses during preparation of the samples of broken mitochondria We have found that transaminase as well as glutamic and malic dehydrogenase are still partially bound to particulate material while the isocitric dehydrogenase is in a freely soluble form. The latter observation is of some significance in connexion with the variability of isocitrate oxidation by mitochondria, especially in the case of 'leaky' particles such as those prepared from mammary gland.

For the calculation of the percentage concentration of individual enzyme protein in mitochondria the activity per mgm. of pure enzyme has to be known. None of the enzymes discussed has been purified from guinea pig or rat liver, but a preliminary estimate is of considerable interest. Assuming for the rat liver enzyme the turnover and molecular weight of pig heart isocitric dehydrogenase[7] one can calculate that 2 5 per cent of the protein of rat liver mitochondria and twice this amount of guinea pig liver mitochondria consist of this enzyme Similar calculations for the other enzymes estimated give values of the same order of magnitude

We were particularly interested in the relative rates of the dehydrogenases, respiration and transamination The relation between enzyme concentrations and respiration is discussed elsewhere[3] Here we shall concern ourselves with the question as to how the concentration and kinetic characteristics of transaminases fit in with the observations on mitochondrial metabolism of glutamate, aspartate, α-oxoglutarate and oxaloacetate.

Table 1 SOME ENZYME ACTIVITIES OF DISRUPTED MITOCHONDRIA AND THEIR RELATION TO THE RATE OF RESPIRATION OF INTACT MITOCHONDRIA

Reaction	Rat liver	Guinea pig liver	Guinea pig mammary gland*
Glutamate + oxaloacetate to aspartate + α-oxoglutarate	1 2, 1 0, 0 92	1 0, 0 5	0 8
Isocitrate + NADP$^+$ to α-oxoglutarate + CO$_2$ + NADPH + H$^+$	0 14, 0 13, 0 13	0 21, 0 41, 0 31, 0 54	0 1
α-Oxoglutarate + NH$_4^+$ + NADH to glutamate + H$_2$O + NAD$^+$	0 16, 0 17, 0 19	0 18, 0 30	none
α-Oxoglutarate + NH$_4^+$ + NADPH to glutamate + H$_2$O + NADP$^+$	This reaction proceeded at about 55 per cent of the rate of the reaction in the presence of NADH		none
Glutamate + H$_2$O + NAD$^+$ to α-oxoglutarate + NH$_4^+$ + NADH	0 081, 0 035, 0 074	0 03, 0 08, 0 06, 0 04	none
Glutamate + H$_2$O + NADP$^+$ to α-oxoglutarate + NH$_4^+$ + NADPH	This reaction proceeded at about 55 per cent of the rate of the reaction in the presence of NAD$^+$		none
Malate + NAD$^+$ to oxaloacetate + NADH + H$^+$	0 36, 0 28, 0 30	0 06, 0 0925	
Oxaloacetate + NADH + H$^+$ to malate + NAD$^+$	3 25, 2 75, 2 98, 3 96	2 50	0 6, 1 4, 0 8
Respiration-rate of intact mitochondria in the presence of ADP inorganic PO$_4^{=}$ and citric acid cycle substrates	0 12–0 14	0 04–0 05	0 04–0 05

The results given in this table are in μmoles of substrate utilized per min per mgm mitochondrial protein at 25° C under conditions of optimum *p*H, substrate, coenzyme and metal ion concentrations, with the exception of NH$_4^+$ during glutamate formation which was 3 33 m*M*

* Examination of the supernatant obtained after centrifugation of mammary gland mitochondria indicates considerable leakage of enzymes from these respiratory particles

Kinetic Characteristics of Transaminase

Two types of enzyme preparations were used for kinetic measurements on various transaminase reactions The transaminase of mitochondria from guinea pig liver and mammary gland and from rat liver were examined in suspensions of broken mitochondria as used for the enzyme assays described above Secondly, we used a highly purified preparation of transaminase from pig heart, which corresponded to that described by Jenkins, Yphantis and Sizer[8] This gives a basis of comparison with an enzyme preparation most extensively described in the literature The kinetics of transaminase catalysis can be described by the scheme shown in Fig 1, in which each step is reversible

This scheme is formally the same as that described by Gutfreund and Sturtevant[9] for hydrogen transfer via enzyme-bound flavin adenine dinucleotide, but the rates of the individual steps of the transaminase reaction are so much faster that even rapid reaction techniques have so far only helped to confirm an order of magnitude for the rates involved

It has been shown[10] that the reaction of the pyridoxal enzyme from pig heart with alanine to form pyridoxamine enzyme and pyruvate is fairly slow (half-time approximately 6 min with alanine 2×10^{-2} *M*), the reverse reaction with pyruvate is at least 100 times faster The reactions of the pig heart enzyme with aspartate or glutamate was known to be much more rapid but no attempt had previously been made to determine its rate We have made some preliminary observations on the rate of forma-

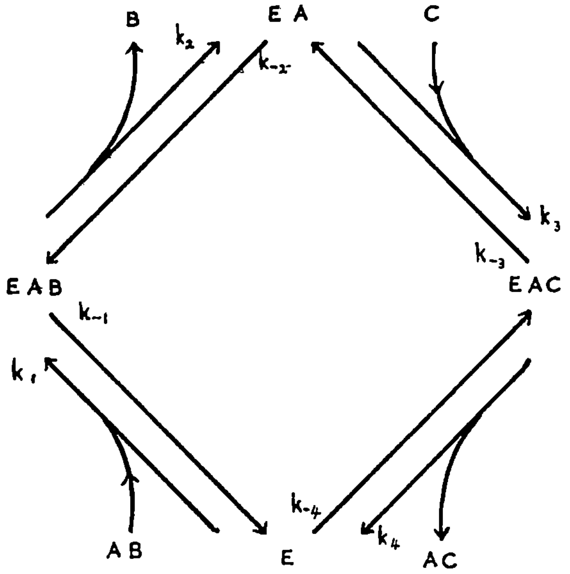

Fig. 1. *E*, pyridoxalphosphate enzyme; *AB*, amino-acid substrate; *EAB*, Michaelis complex; *B*, ketoacid product; *EA*, pyridoxaminephosphate enzyme; *C*, ketoacid substrate; *EAC*, Michaelis complex; *AC*, amino-acid product

tion of pyridoxamine enzyme in the presence of 0·05 *M* aspartate. The reaction was followed in a rapid-reaction spectrophotometer at 365 mμ. The method used was only capable of giving an approximate value for the half-time of the reaction (5 m.sec at 25°). The difficulty of obtaining accurate kinetic constants is due to the fact that the earliest observation is made at a time at which the reaction is about half-way completed and the complication of the reverse reaction discussed later puts special demands on accurate observations over the whole time course of the reaction. It is, however, of great interest to get this approximate value for the velocity of the very rapid pyridoxamine enzyme formation, especially in view of the fact that this reaction is characterized by k_2 (see Fig. 1), which will be shown to be the smallest of four forward reaction constants. The following calculation is of interest, though it is based on a number of approximations. Jenkins and Sizer[11] give the results of an experiment designed to study the equilibrium

$$\frac{(\text{enzyme-pyridoxamine})\ (\alpha\text{-oxoglutarate})}{(\text{enzyme-pyridoxal})\ (\text{glutamate})} = K$$

The data given over a wide range of the two forms of the enzyme do not fit any simple model of a reversible reaction, but at low glutamate concentration one can conclude that the rate of the reaction of the pyridoxamine enzyme with α-oxoglutarate is approximately 100 times as fast as the reaction of the pyridoxal enzyme with glutamate. In any discussion of metabolic control at the point of one enzyme, one is concerned with the relation between the Michaelis constant and the steady-state concentration of the substrates. If two substrates—donor and acceptor—can influence the rate, then one is also concerned with the conditions under which the concentration of one or the other of these determines the rate of the overall reaction. The tissue concentrations of α-oxoglutarate are usually much lower than those of glutamate and the concentration of oxaloacetate is only of the order of 10 μM [1,12]. The value for *Km* for oxaloacetate with mitochondrial transaminase is therefore of particular interest. We have determined this in the following manner with our rat liver mitochondrial preparation. The assay for glutamate to oxaloacetate transamination was carried out over a range of substrate concentrations under initial conditions of equal amino donor and amino acceptor concentrations.

After the optimum substrate concentration (5×10^{-3} *M*) had been determined a series of experiments at constant glutamate concentration (7×10^{-3} *M*) and a range of oxaloacetate concentrations ($0·83 \times 10^{-5}$ to $1·67 \times 10^{-2}$ *M*) was carried out. The *Km* for oxaloacetate was found to be approximately 9 μ*M*. At high oxaloacetate concentrations (above 5×10^{-3} *M*) inhibition of the transfer reaction occurs. This inhibition is of no biological significance since oxaloacetate is a very potent inhibitor of succinic and malic dehydrogenase at much lower concentration and could never build up to this level. It is, however, important to take this inhibition into account when kinetic investigations are attempted with less sensitive assay procedures.

A series of determinations of *Km* for the aspartate to α-oxoglutarate transamination were carried out with mitochondrial preparations from guinea pig liver and mammary gland and the purified pig heart enzyme. When the acceptor and donor concentrations are equal the following values for *Km* are obtained: guinea pig mammary gland, 1·15 m*M*, guinea pig liver, 0·77 m*M*, pig heart transaminase, 4·0 m*M*.

When the α-oxoglutarate concentration is reduced below that of aspartate, no significant reduction in the rate of the reaction is observed until the acceptor concentration is one-tenth of the donor concentration. This indicates that during the conditions of the *Km* determinations the reaction of aspartate with the enzyme is rate determining and the *Km* for the α-oxoacid is much lower than that for the amino-acid. This is analogous to the relationship between glutamate and oxaloacetate discussed above.

Latency and Metabolic Control

The latency of dehydrogenases in intact mitochondria has recently been discussed by Bendall and deDuve[13], and Boyd[14] describes similar phenomena for mitochondrial transaminase. In the report[14] on transaminase it is concluded that the activity for transamination from aspartate to α-oxoglutarate is increased up to three-fold on disruption of mitochondria. The following phenomena can be responsible for the so-called latency of transaminase and perhaps also of other mitochondrial enzymes.

(1) *Compartmentation and permeability* may make available only limited amounts of substrate to the enzyme and may select preferentially either internally generated or externally added substrates. Local accumulation of substrates and/or products can either accelerate or inhibit.

(2) *Structural alterations* of enzymes bound to mitochondrial enzymes or concentrated within compartments can also affect their activities. Several non-mitochondrial enzymes are known to be less active when they aggregate in solution. Fasella and Turano[15] have shown that transaminase forms a dimer with a dissociation constant of 10^{-8}–10^{-7} *M*. The dimeric form has only about 5 per cent of the activity of the monomeric form. Glutamic dehydrogenase, on the other hand, dissociates under a variety of conditions to form inactive sub-units[16]. It appears, however,

that many of the enzymes discussed are, at least partially, bound to the structural material of mitochondria and one has to be cautious in accepting that the conditions causing structural changes in enzyme molecules in free solution would cause similar changes in the bound form of the enzyme

Under physiological conditions a number of factors must co-operate in primitive control of mitochondrial pathways This is the type of control not involving the formation of new enzyme protein The transaminase activity of mitochondria is more than sufficient to convert all the oxaloacetate which can be produced by the citric acid cycle into aspartate, provided a reasonable concentration of glutamate (0 1–1 mM) reaches the transaminase The results of the present investigation show that the enzyme concentrations, kinetic parameters as well as the relation between oxaloacetate concentration and Km are consistent with the pathway for glutamate oxidation outlined in the introduction If it were indeed true that all the oxaloacetate is converted into aspartate, which in turn is used for the biosynthesis of proteins and nucleic acids, then the citric acid cycle would be disrupted There is insufficient information about the potential activity of condensing enzyme and about its affinity for oxaloacetate to predict whether the condensation reaction can compete successfully for oxaloacetate with the transamination system even in the presence of glutamate

The elucidation of the control of the citric acid cycle and of its supply of substrates and disposal of products is both extremely important and, because of its many complex control points, a great intellectual challenge This problem will be readily soluble when the type of information discussed for some enzymes in this article has been obtained for all the enzymes concerned and when tracer kinetic investigations with labelled intermediates have given full information about the relative availability for intramitochondrial enzyme reactions of externally added and internally generated substrates and products

DIAPAUSE IN AN AQUATIC MYMARID

By Miss D. J. JACKSON
North Cliff, St. Andrews

CARAPHRACTUS CINCTUS Walker parasitizes the eggs of various Dytiscidae[1] and is easy to rear in captivity on the eggs of the water beetle *Agabus bipustulatus* L The entire development of this mymarid occurs under water within the host egg, the shell of which is transparent The larvæ, usually 2 or 3 in each egg, are clearly visible during their later stages, so the time of pupation is easily determined

Four to five generations of *Caraphractus* have been bred in a year in an unheated north room with a large uncurtained window at my house in St Andrews The last generation of the year undergoes diapause in the full-grown larval (prepupal) state. Such diapausing larvæ may be found in some eggs in September and usually in all eggs by the end of October Pupation occurs in the spring and the majority of the adults emerge from March to May The eggs of *A bipustulatus* do not diapause but develop at all times of the year when the temperature is suitable

In some parasitic Hymenoptera which diapause in the last larval instar[2,3], it has been found that maternal physiology may influence the incidence of diapause in the offspring, either by diet[2,3], by ageing of the females[3], or by rearing the females at low temperature[2,3] In *Caraphractus* the adult female has never been seen to feed, and observations on the laying of old females previously deprived of host eggs showed that retention of the eggs in the ovaries of this insect (which has a very short adult life) was not a factor promoting diapause in the offspring By exposing host eggs at various stages of parasitism to low temperature (5° C) in August, development was retarded, but there was no diapause in the chilled generation and no increase in diapause in the offspring

A succession of generations was obtained during the diapause season', September–March, by rearing *Caraphractus* in a constant-temperature room at 17 5° C in continuous fluorescent light of 9 ft -candles, each generation developing in a little more than three weeks, normally without diapause (Table 1, exp 2) When host eggs with young larvæ were transferred from this constant-temperature room to the north room where diapause normally occurs, the majority of the larvæ went into diapause, while the reverse experiment (moving parasitized eggs from north room to constant-temperature room) resulted in direct development of all the larvæ When females, reared in this constant-temperature room, were transferred to the north room to breed, they produced, from the middle of September to the end of December, 98 1 per cent diapausing offspring in 264 parasitized eggs Since the temperature of the north room, though variable, was mostly 14°–16° C and so not very much lower than the constant-temperature room, it seemed probable that the long hours of darkness at this season were responsible for inducing diapause in the developing larvæ

C T R, constant temperature room

Experiments with different photoperiods were then tried, first by exposing newly parasitized eggs during December to daylight from a north window and supplementing this with artificial tungsten light of 30 ft -candles in the evening, a method similar to that used for mosquito larvæ by Baker[4] The temperature averaged min 10 5°, max. 13 5° C With only 3 hr. of artificial light, all the larvæ went into diapause, with 6–6½ hr of artificial light the diapause was 88 3 per cent, though the total light (including morning twilight) was about 15–16 hr Controls, covered during artificial light, gave 97 per cent diapause Further experiments, some in ventilated tea-chests and others in constant-temperature rooms, showed that direct development occurred during continuous light, or with 3–5 hr of darkness (Table 1, exps 5 and 6)

The effect of a short photoperiod (7½ hr.) in promoting diapause from ovipositions in April and May has recently been demonstrated, for 98 6 per cent of 306 parasitized eggs so treated went into diapause, while 221 controls, exposed to daylight in the same (north) room at the same time, have all given direct developing *Caraphractus*

Experiments have been undertaken to find out the lowest intensity of light required during the night to prevent diapause By using daylight from a north window in February and March and two 5-W neon bulbs all night from 4 30 p m to 8 30 a m, and placing 264 parasitized eggs at varying distances from the light, direct development of all the parasites occurred, though the light they received at night was only 0 03–0 3 ft -candle Controls kept in the same room, in darkness during artificial light, gave 82 5 per cent diapause The temperature averaged min 12 5°, max 15 5° C Three further experiments were conducted in the spring in tea-chests, using for 15 hr a tungsten 25-W bulb giving 12 ft -candles and for 9 hr cresyl blue filters adapted to give light intensities of 0 8, 0 25 and 0 05 ft -candle As a result, all the successfully parasitized eggs in each experiment (a total of 513) gave direct developing *Caraphractus* The average minimum and average maximum temperatures in these three experiments were 13 5° C and 16 5° C

These results show that *Caraphractus* is sensitive in the larval state to light of extremely low intensity It seems likely that in ponds direct development will only occur with long daylight hours combined with faint light at night (twilight), or with a few hours of darkness. In other insects[5–8], long day-lengths at medium temperature promote direct development, with *Caraphractus*, 9 hr of complete darkness suffice to induce diapause in the great majority of specimens (exp. 7) Experiments have shown that low temperature in this insect is not the deciding factor, and in autumn, when reared in the north room, with an open window, diapause started before the cold weather set in. At the commencement of the 'diapause season' there is individual variation in the susceptibility of the larvæ, and eggs, parasitized by the same female within 5 min of each other, may yield either diapausing or non-diapausing *Caraphractus*. Moreover, it sometimes happens that the development of two individuals within the same host egg may be of both types, though the eggs producing them were laid at one thrust of the ovipositor This variation disappears as the hours of darkness lengthen

From May until August direct development normally occurs and this coincides with the long twilight of the summer nights and the absence of astronomical darkness The onset of diapause in the autumn sets in at a time when there are about 6 hr of astronomical darkness, which increases in early October to more than 8 hr ; this may well be the 'clock'[9] to which the larvæ respond. Once in diapause. *Caraphractus* can withstand some desiccation, even if the host eggs collapse during drought Diapausing larvæ can also survive for days in freezing water (0–1 to 0–3° C) and when removed to a suitable temperature, pupation may occur promptly When the larvæ are not subjected to frost, the diapause runs its course and usually extends over several months, but is sometimes greatly prolonged

The experiments in the constant-temperature rooms were carried out in the Natural History Department of the University of St Andrews and I am grateful to Prof H G Callan for affording me these facilities and to Dr C Muir for the valuable help he has so generously given me with technique and light measurement Prof and Mrs Stibbs have kindly provided me with useful information regarding the duration of astronomical darkness in the latitude of St Andrews

HUMANITIES OF SCIENCE

Science since Babylon

By Prof Derek J de Solla Price Pp x+149 (New Haven, Conn , and London Yale University Press, 1961) 4 50 dollars 37*s* 6*d*

THIS book, Prof Price tells us, had its origin in a set of five lectures given under the auspices of the Department of History at Yale University in 1959 It makes no claim to be a history—even a historical sketch—of 'science since Babylon', but rather by reflecting on certain special aspects of that history to gain some insight into why, or in any event how, science has come to be what it is, and thence to deduce the likely course of its future development The whole thus constitutes an essay in what Prof Price wishes to call "the humanities of science"

In five chapters the author approaches the question along three fairly distinct roads the thesis that the character of a scientific epoch is largely conditioned by the instruments available, hence by the special skills of the contemporary 'practitioners', a somewhat detailed examination of the great 'mutation' in physics consequent on Roentgen's discovery of X-rays, and a roughly statistical analysis of the growth of science deduced from such 'pointers' as primary periodical publication, abstracts, individual papers, numbers of active scientists and universities

Despite Prof Price's well-known virtuosity in the first field, here amplified by some fascinating 'revelations' of his methods, belief in the thesis is not likely to be strengthened by some of the arguments which are adduced What are we to make of the statement (pp 51, 13) " that it was the Germanic region of Luther rather than Catholic Italy that saw the revival of astronomy by Regiomontanus [d 1476], Kepler and Copernicus" ? Or by the description (p 61) of Hooke as an ingenious artisan " . who though reasonably educated [Westminster School and Christ Church, Oxford] had no special training in science other than by apprenticeship ['research assistant' to Willis and later Boyle] ?" Who among the early Fellows of the Royal Society, we may ask, had a better preparation in 'science' ?

On the other hand, Chapter 5, entitled "Diseases of Science", " its superabundance of literature, its manpower shortages, its increasing specialization, its tendency to deteriorate in quality"—together with the epilogue, entitled "The Humanities of Science", constitute for the reviewer alike the most convincing analysis of the terrifying *djinn* that optimistic Western man has released from its bottle, and a carefully considered justification for the establishment of 'humanities of science'—call it what you will—as a separate discipline For this reason *Science since Babylon* is an important, possibly a very important, contribution It is all the more regrettable that it is exorbitantly priced

W P D WIGHTMAN

A SHORT HISTORY OF SCIENCE

The Mechanization of the World Picture

By Prof E J Dijksterhuis Translated by C Dikshoorn Pp viii+539 (Oxford Clarendon Press , London · Oxford University Press, 1961) 105*s* net

TRIPLY laden by its burden of price, bulk and title, this book cannot be expected to join the ranks of best-selling general histories of science However, its contents should and probably will be made known to the ever-increasing audience for the history of science Since the publication of Burtt's pioneering work some thirty-five years ago, the 'metaphysical' side of the rise of modern science has received increasing attention, and there is now a fair selection of popular books presenting this story Up to now each author has had to dig for himself in the secondary literature, scattered among many journals and written in all the European languages Now those who teach and write on the history of science have a coherent and scholarly account, written in English and with a comprehensive bibliography There is no longer any excuse for ignorance Also, those who want to learn something of the history of science and are not satisfied by vulgarization, however high, can study this book with profit and satisfaction.

Prof Dijksterhuis gives us an example of how to write the history of science In each of the many topics he covers, he describes briefly what he is going to discuss, and (more important) mentions relevant topics which he is not going to discuss The history of science has been plagued too long by smash-and-grab methods where one 'scientific' contribution of a man is described and analysed, while the philosophical, religious or social thought in which the contribution was originally embedded is left unmentioned Also, it is clear that he has thoroughly mastered the technicalities of each problem, and not contented himself with understanding only that part which could easily be popularized This produces greater accuracy on small and large points His is the only general account of seventeenth-century mechanics which mentions the significant fact that Newton's laws do not use time-derivatives , "$F = ma$", as an explicit statement, dates from Euler Another example is his simplified diagram of the Ptolemaic world-system no other such diagram shows both the deferents of the inner planets, and the epicycle-arms of the other planets, as roughly parallel to the line joining Earth and Sun

The first half of the book is devoted to the background in ancient and medieval thought The two most attractive problems, cosmological speculation and the causes of motion in inanimate bodies, receive their proper place in the complex of philosophical problems on the nature of reality and the nature of change Prof Dijksterhuis covers the whole range of the exact sciences and philosophical thought in classical antiquity. He never describes a result without criticizing it, and from his criticisms emerges a coherent picture of the intellectual limitations of the 'science' of the time. He also has a good sense of what can be compressed, and what cannot; where the scientific technicalities are not important for the general story, they are pruned drastically (with a reminder of what is being left out). Aristotle's philosophy is given detailed attention, and the beautiful coherence of the whole system is exhibited clearly.

The section on scholastic 'science' is most illuminating. Through the work of Dr Crombie and Prof Clagett, we have been approaching a balanced appreciation of the achievements of this tradition, and developing general ideas on the causes of its fatal limitations. In each of his discussions Prof Dijksterhuis illustrates the interpenetration of scientific thought with problems of logic, metaphysics, and theology. He also sketches in the medieval world-picture, and shows clearly how this conditioned the manner of approaching, and solving, scientific problems. The characteristic 'double-think' solution of the practical problem of the conflict of science with theology is described as well as can be done by a scholar living in a free society.

The second part of the book, on the Renaissance and the seventeenth century (concluding with Newton), offers somewhat less. We are not within sight of a synthesis of what happened between Oresme and Galileo; and on the development of mechanics in the seventeenth century there is already a fair literature. This is not to say that Prof Dijksterhuis provides only well-worn material; his discussion of the continuous tradition in the problem of change and composition (What happens to the qualities of the original substances?) lights up untrodden pathways. But nowhere does he discuss in general terms the astonishing intellectual mutation which took place at the beginning of the seventeenth century, when a world-picture much like our own was suddenly conceived and propagated, rendering nearly irrelevant centuries of philosophical thought, and providing a framework in which modern science could be created.

It is unfortunate that the author was not able to revise the text (originally published in Dutch in 1950), for the present book is essentially based on work carried out in the 'thirties, with additions from the War and early post-war years. Much has been achieved in the history of science in the past decade; it is a tribute to Prof Dijksterhuis's maturity of judgment that his history could be enriched, but nowhere seriously challenged, by more recent work.

COSMICAL LANGUAGE

Lincos

Design of a Language for Cosmic Intercourse, Part 1. (Studies in Logic and the Foundations of Mathematics.) By Dr Hans Freudenthal. Pp. v + 224. (Amsterdam: North-Holland Publishing Co., 1960.) 45s.

ONE needs must take seriously a monograph in the series Studies on Logic and the Foundations of Mathematics edited (*inter alia*) by so distinguished a mathematical logician as L. E. J. Brouwer. If its ostensible aim were self-evidently *en rapport* with the title of the series, the editors of *Nature* could have chosen few people more unfitted than myself to respond to a request to review it. Their only conceivable motive for doing so is that I once (ten years ago) gave, at its request, an address (*Astroglossa*) to the British Interplanetary Society on the theme which the subtitle of this monograph discloses. The recapture of echoes from radar signals transmitted to the Moon had then lately made conceivable, if none the less unlikely, intercommunication between ourselves and beings, if such there be, on Mars or Venus.

This was confessedly a *jeu d'esprit* for an evening's entertainment, but it had an undertone of serious intention, as there disclosed. Should contact between ourselves and extra-territorial occupants become possible, the success of the enterprise would be a challenge compelling us to retrace our steps from traditional methods of teaching existing terrestrial languages parrot-wise by paradigm or by repetition. We should indeed have to undertake an exacting revaluation of the semantics of so-called natural languages and of syntactical obscurities which do not impede communication between individuals who share explicitly, or at least implicitly, a common social context of discourse. However fruitless *vis à vis* the ostensible outcome, the undertaking might therefore prove to be worth while if it put the spotlight on semantic refinements we should advisedly incorporate it in an ideally constructed global auxiliary, or if it exposed defects of imparting instruction in a so-called natural language if adopted as a medium of international communication.

Accordingly, I would be the last to dismiss as crackpot a project so grandiose as *Lincos*. Dr Freudenthal and I at least have common ground with respect to the initial stages of the programme. If we postulate the existence of hypothetical extra-terrestrial beings at least as intelligent as ourselves, our only common denominator of communication in the first phase of a protracted tuitional process would be the integers. Whence we may conceivably proceed by easy stages from conveying simple algorithms to non-visual geometry, for example, by exemplary definition of a radio signal *and so on and so on* to specify trigonometrical ratios as infinite series. How far the introduction of the symbolical logic of Dr. Freudenthal would help engineers on the job to carry out this assignment is not fully clear to me, but I concede that I dismissed lightly as too obvious the theme of a second stage here set forth by himself in a symbolism tailored as elsewhere to the Russell–Quine tradition of logistic. Following stage 1 (that is, the domain of mathematical discourse), Dr Freudenthal devotes a chapter to the concept of time. Here he proposes that we can make use of varying signal frequencies to establish what we each adopt as our units of time, whence *pari passu* our concept of frequency.

Thereafter, Dr Freudenthal (whose next chapter is "Behaviour", that is, relations involving different individuals at the transmitting or at the receiving end) parts company abruptly with me. I have stated, and still hold, that the next imaginable step would be to establish a common factual framework of semantic reference. At this stage, the only common field of factual experience which the parties could explore would be celestial occurrences (for example, eclipses, conjunctions and occultations), and this our vocabulary of time signals would have now made practicable. Thereafter, we might conceivably learn to convey the structure of our several planetary crusts and atmospheres in terms of spectrum frequencies It seems to me that the last topic about which we could hope to achieve understanding would be the actions of persons in general, and the concept of the ego in particular

How Dr Freudenthal sidesteps this hurdle, I do not follow It may be that he will make himself more intelligible later in Part 2 However, in justice to him, one must here say that his main pre-occupation is not with the factual sequence of the tuitional process In accordance with the aim of the series in which the monograph appears, his paramount concern is to equip the syntax of interplanetary (or intergalactic) communication with a symbolism consonant with the requirements of a two-valued logistic rejected by some mathematicians in the forefront of bull-dozing the foundations of mathematics as such and (in my view) totally inadequate for the requirements of the biological sciences. The outcome may usefully confer on symbolic logic an agreeably topical flavour for the relief of students compelled to take an examination in the subject From any other point of view, Dr Freudenthal has failed to convince me that his programme is very profitable, and my reluctance to concede that it is so gains force from two considerations

One is that examples cited to show how symbolic logic makes manifest semantic and syntactical pitfalls of common speech are not unfamiliar to students of comparative linguistics, who draw on a much richer (and more relevant) fund of material The use of two particles of relation should make this sufficiently clear In Teutonic and Romance languages we have one word for our *always* (German *immer*, Swedish *altijd*, French *toujours*), but Welsh distinguishes *bob amser* (= *each time*) from *yn wastad* (= *ceaselessly*) Again English *with* and French *avec* cover both Welsh *ag* (= *by means of*) and *gyda* (= *in the company of*)

Another doubt will disturb the reader who is unrepentantly sceptical about the extent to which logistic can make the semantic and syntactical deficiencies of common speech more explicit than can the study of comparative linguistics On p 104 ("Behaviour") we meet

$$\text{Ha Inq Ha}\cdot\text{—}\,t_1t_3\ \text{ Hb Enu ? = .Car Etc}$$

$$\text{Sed }t_1t_3\text{ Hb Cpu ? = Car Etc}$$

The intention in this context is to introduce a distinction between two uses of *but*, symbolically denoted TAN (Lat. *tamen*) and SED (Lat) Do we have to invoke logistic analysis to do so ? Assuredly no Dr Freudenthal has to explain this distinction in the text through the medium of common speech, but it will not necessarily be front-page news to a philologist or classical scholar already familiar with *tamen* and *sed* Since the engineer will have to recode in appropriate radio signals any symbols in which we formulate our curriculum of interplanetary (or intergalactic) tuition, all that is relevant to the credentials of what we use is whether the terms and constructions conform to the requirements of rigorous semantic rectitude If so, it is therefore difficult to see why we should add to his or her difficulties by using an unfamiliar code for what a more familiar one could do equally well with a little premedication

LANCELOT HOGBEN

A ROMAN CATHOLIC VIEW OF EVOLUTION

Evolution and Christians

By Philip G. Fothergill Pp xix + 15 plates (London Longmans, Green and Co , Ltd , 1961) 42*s* net

DR. FOTHERGILL, in addressing his fellows of the Roman Church on the matter of evolution, has undertaken an important and difficult task, and has carried it out with a meticulous thoroughness and a scrupulous integrity His book is an encyclopædia of information about the history, progress and present position of the case for evolution so far as this can be stated within the strict limit of Catholic dogma He has presented with a wealth of detail the familiar story of Darwin's evidence in the *Origin of Species*, of the subsequent developments in taxonomy and palæontology, of the impact of genetics and of the varied fields of study since involved He has then dealt at even greater length with heredity, the matter of chromosomes, genes, and mutations, with the relevance of cytology and serology, and with innumerable records of experiments with *Drosophila*. Finally he discusses problems of isolation, of the effects and limitations of selection and of hybridization, and faces the question how far does all this elaborate and highly technical research enable us to point to the appearance of new species arising under the conditions of neo-Darwinian theory and precisely scientific control

In these long and difficult records he does his best to state and expound the innumerable polysyllabic names that each research department applies to its subjects—a heroic task which makes his book almost incomprehensible to the layman—to furnish it with good and relevant diagrams and illustrations, and to insert quotations, short and long, from a large number of writers more or less well known He also quotes a few critics of his views, especially Dr Douglas Dewar and Prof G Gaylord Simpson He is himself very ready to admit that much of what he describes is inconclusive—some of it is also irrelevant His own final conclusion appears to be that though the mass of data give a strong case for accepting evolution as a hypothesis, the only clear examples of new species recent or demonstrable are those of allopolyploidal plants and fertile hybrids like the common hemp-nettle or Townsend's cord-grass—our notorious enemy in the battle of the Western Approaches

The fact is that his task as limited by Catholic orthodoxy is scarcely possible, and that for three chief reasons First, he realizes and complains that without a philosophy of science it is impossible to relate evolution to any coherent interpretation of the world as we know it, the details which he reports so carefully become trivial and meaningless Yet he is debarred by ecclesiastical authority from making any reference to philosophic evolutionists unless, like Sir Julian Huxley, they are avowedly hostile to the faith or like the one or two unknown Catholics whom he quotes accredited by it It is astonishing for an Englishman who has spent all his life with the problems of evolution to read a book on it in which there is not a single mention of Bergson or Lloyd Morgan, Samuel Alexander or A N Whitehead, of emergence or of holism or any other of the systems which have interpreted the process and made the details meaningful.

Secondly, and presumably because of the dogma that "animals have no souls", he never touches on the large and exciting field of comparative psychology, or on the evolution of the behaviour-patterns and instinctive responses which mankind has so obviously inherited and to which all post-Freudian analysis has directed attention. The idea that each and every "intellectual soul" of man is a special divine creation if tenable must surely be adjusted now so as to allow room for an age-old substratum of animalisms conditioning our mind and morals as they do our bodies.

Thirdly, he writes always within the strait-jacket of Papal orthodoxy, much of it formulated in pre-Copernican and all of it except one encyclical in pre-Darwinian days. Though much of this may be held to deal with matters outside the range of present-day science, it has, even so, corollaries of dogmatic status, for example, the historicity of Adam and Eve, which bear directly on his theme. Moreover, does he really think that in matters demanding not only religious but also scientific, historical and ethical experience, the Vatican is the proper and infallible authority to which every other expert must yield unquestioning obedience? CHARLES E. RAVEN

CLIMATES OF THE PAST

Descriptive Palaeoclimatology

Edited by A. E. M. Nairn. Pp. xi+380. (New York: Interscience Publishers, Inc., London: Interscience Publishers, Ltd., 1961.) 11 dollars; 80*s*.

GEOLOGISTS who have struggled to interpret past climates will welcome this book for its wealth of factual information and for the critical way in which most of the authors have approached their special interests.

The first chapter, apart from a brief introduction by the editor, is a summary by Lamb of the nature and causes of the world's climate to-day. It is not easy to read, but it is extremely informative. Then follows a series of chapters each written by a specialist and dealing with the separate criteria which can be used as a means of assessing at least some facet of climate. These may be pure physical measurements (palæomagnetism, the ratio of oxygen-16 to oxygen-18), geological observations (the dips of æolian sandstones, the evidence of the presence and extent of ice), physical chemistry (evaporites and red beds) or biological deductions (from vertebrate, invertebrate or plant fossils). Finally, there are four chapters in which are traced the climatic changes over a large part of geological time in Europe and North America, the Far East and Gondwanaland.

Flint, dealing with glaciation, perhaps stands on the firmest ground, for the conversion of water to ice has a well-known climatic relationship and the presence of glaciers or permanently frozen ground in many cases gives rise to conclusions about climate which are without ambiguity. Much more difficult to interpret are evaporites and red beds, and the authors of these sections are understandably cautious in their conclusions. This welcome attitude is indeed apparent throughout. In dealing with the oxygen isotopes, for example, Thorley does a great service in pointing out the assumptions which have to be made before this method can be used for temperature determinations—assumptions which can too easily be ignored by stratigraphers eager to use a physicist's measurements to support a theory.

Perhaps the biologists are the most cautious of the authors, for all stress the difficulty of using the present as a key to the past when ancient floras and faunas are specifically and generically so different from those of to-day. On the whole, the greatest reliance is placed on anatomy, for it seems that certain modifications of structure, similar in widely diverse creatures, are adaptations to certain extremes of climate.

Throughout the book, emphasis is placed on polar wandering and continental drift. The palæomagnetists accept it without question, for their results would be largely meaningless without it, but they still have a long way to go before they present a conclusive and agreed story. Thus Nairn's equator-positions for the Trias of Europe (Chapter 7, Fig. 9), Africa and North America (Fig. 7) seem to provide an insoluble problem of drift if his three lines are to join into a continuous girdle at one moment of time. The palæontologists are more non-committal about polar shift, while conceding the necessity for great climatic change in the present polar regions. Van Houten's examination of the significance of red beds tends to support wandering rather than static poles, but on the other hand, Green feels able to explain the distribution of evaporites without recourse to drift or polar change.

As a whole, the book is a mine of information and both a stimulus to enthusiasm and a corrective to over-enthusiasm in approaching a difficult problem. Its copious references are international in character though scanty from beyond the Iron Curtain. It would be churlish to point out a few misprints and errors of translation and more to the point to congratulate the editor on welding together the contributions of fifteen authors from seven countries.

F. W. SHOTTON

BIRDS OF TROPICAL PARADISE

Birds of Trinidad and Tobago

By Dr. G. A. C. Herklots. Pp. 287+20 plates. (London: William Collins, Sons and Co., Ltd., 1961.) 42*s*. net.

THE islands of Trinidad and Tobago, the southernmost of the West Indian chain, have a combined land area of about 2,000 square miles, Tobago being very much the smaller, and at 10° N. and about 10 miles from Venezuela on the South American mainland, they are truly tropical. Being small islands they possess a high proportion of coastal land; in Trinidad there is a range of mountains (in the north) topping 3,000 ft. in two places, abundant deep forests, lowland plains, savannahs and extensive swamps; a wide range of habitats that encourage a wide variety of bird species both exotic and interesting.

Without undertaking an expensive safari (of the type so popular with programmers of television) one may seek out and enjoy the sight of a flock of flamingoes (*Eudocimus ruber*) either feeding in swampy land or, at sunset, a blaze of scarlet glory winging its way to roost—a sight not easily forgotten. I have, indeed, photographed a group of these birds feeding quietly on a plot of low-lying coastal land not two miles from the capital city, Port of Spain.

From the islands off the north-west peninsula one may film with ease the superb aerobatic displays of flocks of frigate-birds (*Fregata magnificens*—wingspan up to 7 ft.) as they swoop gracefully to snatch small fish from the surface of the sea with a downward flick of the head, then wheel aloft again, frequently challenged in mid-air by their comrades eager to snatch their prize

In the cool of the thick forests of Trinidad one may see the gaily dressed toucan (*Ramphastos vitellinus*) perched high in the tree-tops or hear its hard crackling call, or one of several parrots and parrakeets common in the forests Even more spectacular are the brilliantly coloured macaws which may be found in and near the Nariva swamp But one may have to look longer to discover the giant nightjar (*Nyctibius griseus*), which is rare and evasive, assuming an erect posture to simulate the elongation of its perch, when danger is nigh It is said that a museum once offered £100 for one of its eggs There is the fascinating guacharo or oilbird (*Steatornis caripensis*) to be found in the caves at Aripo and elsewhere The oilbird nests from year to year in the same place on ledges high on the walls of the cave, so that a truncated cone of guano is built up, in the cupped top of which the new eggs are laid The effect is of rows of artificial stalagmites They feed on the oil-rich berries of certain palms and the young become veritable 'balls of fat' from this rich diet When disturbed an alarm call, like "the cries of tortured men", rings through the cave Being completely nocturnal they are provided with a form of 'radar' which enables them to move freely in the dark caves

On the islet of little Tobago is another interesting ornithological attraction, for here may be seen the greater bird of paradise (*Paradisea apoda*), which was brought from the Aru Islands off Dutch New Guinea to this sanctuary by Sir William Ingram in 1909 His sons donated the island to the British Government on the condition that it be maintained, *in perpetuum*, as a bird sanctuary

Then there is a group of what must be among the most beautiful of all birds—the hummingbirds (Trochilidae) Trinidad has for long been known as the land of the hummingbird' and it is re-assuring to hear from Dr Herklots that there is little reason to suppose that they are not as abundant as ever In all, 17 species are listed, of which Herklots has seen 15 in his seven years on the island Some species are certainly very common and may be observed in gardens in the heart of town, flashing like priceless jewels in the strong sunlight as they sip nectar from flowers such as the ixora or Barbados pride (*Caesalpinia pulcherima*), hovering, humming, perkily prying at each bloom in an inflorescence, then away, with incredible speed

These are but a few of the 415, or so, birds described in this most welcome book One may say that it has been awaited for half a century, since the last comprehensive, descriptive guide to the birds of Trinidad was written (in French) by A Leotaud in 1866 While in its own way Leotaud's book is a classic, it could scarcely be said to be *au courant*, and is in any event rare and almost impossible to borrow Unfortunately, Dr Herklots' book does not bring us quite up to date as he has not managed to find a proportion of the birds listed in the book and has drawn heavily on Leotaud and on the publications of Sir Charles Belcher and G D Smooker, *On the Birds of the Colony of Trinidad and Tobago*, to be found in *Ibis* between 1934 and 1937 This in no way detracts from the practical utility of the present volume and Dr Herklots must be congratulated on the efficiency and clarity of his presentation The glossary, blessedly, precedes, instead of follows, the descriptions and there is a short introduction with two maps For each species there is a precise description followed by notes on nidification, habitat, voice (not in every case), distribution and field identification The plates illustrate some 260 species, about 180 in colour, and are, on the whole, very good indeed, but the majority are head-and-shoulders only Since most of the species are also to be found on the neighbouring mainland, this book is a useful guide for English-speaking naturalists in Venezuela, the Guianas and Brazil, but above all to those interested in the birds of Trinidad and Tobago, this is now the guide of prime importance and, as such, an indispensable one, 'completing' Dr James Bond's *Birds of the West Indies* which omits these islands My only regret is that no photographs were included which would have given those who have not visited the islands some small impression of their charm

L B. QUESNEL

AN ARACHNOLOGICAL ANTHOLOGY

Spiders, Men, and Scorpions

Being the History of Arachnology By Theodore H Savory Pp. 191+15 plates (London University of London Press, 1961) 30*s* net

IN spite of their relatively small numbers, arachnologists have a liking for writing about each other as well as about their subject, and without doubt this has enriched the literature We have already had biographical accounts by W S Bristowe and Pierre Bonnet, and Mr Savory has now taken this a good deal further in his latest book

He has again demonstrated his versatility as a writer in this history of man's relationship with spiders, scorpions and other arachnids, which begins with legend in Ovid's story of Arachne to the outstanding names in arachnology in modern times The first book devoted entirely to spiders was apparently published in 1544 in Basle, but until the seventeenth century the literature appears to have added more in the way of superstitions to the knowledge of arachnology than original observations The story of the development of tarantism, a curious disease which was supposed to be caused by the bite of the tarantula (*Lycosa tarantula,* a wolf spider), is full of interest, however, even though the mystery of how it came about remains The distressing effects supposed to have been produced by the spider's bite could only be relieved by music and dancing, and to-day the only vestige which remains is a dance, the tarantella, probably one of the few contributions made by an arachnid to human culture

Inevitably in a work of this kind a good deal of reference must be made to numbers of minor and insignificant writers for the sake of keeping the record complete Occasionally this makes the reading rather tedious in spite of one's admiration for the industry of the writer in tracing historical data Most of the great names which are familiar to modern students of arachnology are referred to in the later chapters of the book, and Mr Savory's enthusiasm and style give a fresh and personal picture of people who to most of us have never been more than a name attached to monographs or scientific papers The outstanding workers, such as Simon, Pickard-Cambridge, Koch and Thorell, worked mainly on the Araneida, and a good deal of the book is concerned with work on this order Mr Savory considers that the foundation of spider taxonomy was laid by French and German students in the early nineteenth century, of which the publication of Hahn and Koch's *Die Arachniden* in 1831 was the most striking example John Blackwall for Britain made a major contribution in 1861 with his Ray Society volume on *British Spiders*, and the three countries Britain France and Germany perhaps remained pre-eminent in this field until recent times Mr Savory's review does not include post-1958 works and consequently misses H Wiehle's monograph on the Micryphantidae, one of the most important taxonomic works since the War He is perhaps a little unfair to the younger generation of German zoologists, which, he says, "has only just begun to appreciate the Arachnida as subjects for research" In fact, since 1942 more work has been carried out in Germany on the biology and ecology of spiders than probably any other country

This and recent work in other countries emphasize an important historical point not made by the author that the taxonomy of European spiders is now at least sufficiently well known for the main interest of the younger generation of arachnologists to concern themselves largely with population and biological problems This would appear to be the field of investigation for the future, although outside Europe, faunal surveys and taxonomic studies will continue to be necessary for many years to come.

E Duffey

BRITISH MOTHS

The Moths of the British Isles

By Richard South. New edition, edited and revised by H M Edelsten, D S Fletcher and R J. Collins First Series Sphingidae, Endromidae, Saturniidae, Notodontidae, Thyatiridae, Drepanidae, Lymantriidae, and Noctuidae Pp 427+148 plates Second Series Lasiocampidae, Arctiidae, Geometridae, Cossidae, Limacodidae, Zygaenidae, Sesiidae, and Hepialidae Pp 379+141 plates (The Wayside and Woodland Series) (London and New York Frederick Warne and Co , Ltd , 1961.) 35*s* net each volume

INTENDED primarily as a guide to the identification of the larger British moths, this new edition of a standard work fulfils its function more successfully than the editions of 1923 or 1939 mainly through the introduction of improved and completely new colour-plates The original paintings, from which the colour-plates were prepared, are with very few exceptions excellent In the few copies of the new edition examined by me, however, the colour-plates do not always attain the same high standard as the artist's paintings there is a lack of register in many plates and in several of them the red element is weak, resulting in unnatural greenish tones In spite of these drawbacks the plates are far superior to those in any except the first edition, and several plates (especially those of the genus *Eupithecia* Curtis) are as good as any illustrations previously published in Britain Many of the plate legends (for example, Series 1, plate 97) are unfortunately most confusing and will clearly have to be rearranged by the publishers in subsequent editions. References to the corresponding pages in the text have been omitted, as in previous editions, and numerous species exhibiting little sexual dimorphism continue to have both sexes illustrated Of some significance is the introduction of references in the text to figures of the genitalia of some of the more difficult genera (for example, *Procus* Oken and *Hydraecia* Guenée), an indication that externally the species of these genera are extremely difficult to separate and that the colour-plates are of little use as a means of identification The reproduction of many of the half-tone figures is very poor.

Since the publication of the first edition in 1907 the bulk of the text has remained unaltered and, although a thorough revision was clearly overdue, to remedy the haphazard and inconsistent treatment of many species, the opportunity to do this has not been taken New text is therefore restricted mainly to passages of supplementary information, leaving most of the remainder almost exactly as it was more than half a century ago

An important addition is the detailed treatment of several little-known moths, such as *Calamia tridens occidentalis* Cockayne A further improvement is the adoption for the first time in this book of the correct form of scientific nomenclature in accordance with the International Code

The unsystematic arrangement of the various families of moths is regrettable but, as the editors state in the introduction, this is the only way in which both plates and text could be arranged to avoid dividing the section on Noctuidae between the two volumes (a disadvantage of previous editions)

It is remarkable that in spite of the attention given to Lepidoptera by British entomologists, the editors have seldom been able to cite the sub-specific identity of the British representatives of a particular polytypic species—a result of the paucity of taxonomic work on our fauna at the specific and subspecific levels

Although several references to other literature are given in the text, there is still a need for a short bibliography, which could have included some of the more useful general works on British and European Lepidoptera No more than the usual number of minor errors seem to have arisen, but some of these lead to unfortunate confusion concerning identification, for example, on page 347 of Series 1 ab *carthami* Herr -Schaf is wrongly stated to be illustrated by Fig 11 on pl 126

It is disappointing to find that while this new edition is certainly an improvement on those it follows, it does not fulfil the expectations of many entomologists who had hoped for a more radical revision of the text

A Watson

THE GROWING TIP OF PLANTS

Apical Meristems

By Dr. F A L Clowes (Botanical Monographs. Vol 2) Pp viii+217+32 plates (Oxford Blackwell Scientific Publications , Springfield, Ill Charles C Thomas, 1961) 37*s* 6*d* net

DURING the past twenty years or so, there have been many investigations of the apical meristems of plants, an interest which is understandable since these meristems are in a sense regions of permanent embryogeny responsible in most plants for all longitudinal growth and the continued production of new organs The early investigations of shoot and root apices were mainly anatomical, but in a considerable number of the recent investigations biochemical and experimental approaches have shed new light on the behaviour of the apical meristems Although special aspects of this recent work have been reviewed previously, there has hitherto been no reasonably comprehensive account of both root and shoot apical meristems This need has now been met by the new book written by Dr Clowes

Although Dr Clowes' own research work has been mainly on root apices, shoot meristems receive adequate consideration; in fact eleven of the seventeen chapters deal mainly with shoot apices Recent work involving new techniques is discussed in some detail, but the anatomical side is not neglected Chapters on planes of division in shoot and root apices include discussions of the tunica-corpus hypothesis of the shoot apex and of the similar, but less well-known, Korper-Kappe hypothesis of the root meristem A complete chapter is devoted to the bearing of the evidence from chimeras on controversies relating to the shoot apex The sections of the book dealing with the rates of cell division in both root and shoot apices are particularly informative, and it would seem that the newer techniques, including autoradiography, have demonstrated the existence of a 'quiescent' centre in the root apices investigated It has also been shown that, in opposition to the views of the French school, there is no 'méristème d'attente' in the shoot apex

The book is not restricted to a consideration of apical meristems in the narrow sense, but covers in addition such topics as the development of leaves, the determination of sites of leaves, the differentiation and origin of procambium, latitudinal growth in apices and the formation of floral apices There is also a detailed consideration of differentiation in the root apex

The text figures of apices are not very numerous, but are supplemented by 32 photographs including some striking autoradiographs of shoot and root apices The clear readable style is an admirable feature of the book, which is a useful addition to the new series of botanical monographs. A ALLSOPP

ELECTROLYTES AND PLANT CELLS

Electrolytes and Plant Cells

By Prof G E Briggs, Dr A B. Hope, and Prof R N. Robertson (Botanical Monographs, Vol 1) Pp x+217 (Oxford Blackwell Scientific Publications; Springfield, Ill · Charles C Thomas, 1961.) 40*s* net

THE stated purpose of this new series of Botanical Monographs is to inform the advanced student, assist the lecturer and be a point of departure for the specialist The first volume admirably fulfils these aims

Forty pages at the beginning are devoted to an account of the physical properties of electrolytes in solution The principles of ionic exchange receive little attention, but diffusion and Donnan equilibria are dealt with handsomely Plant cells merit no more than passing mention until Chapter 4, which contains an elementary account of the gross structure of three types Chapter 5 deals with fine structure as revealed, albeit still imperfectly, by electron-microscopic investigations One is left wondering how soon it will be possible to apply the physico-chemical principles outlined earlier to the immensely complex and ever-changing cytoplasm At present only the inert cellulose wall seems amenable to such an approach

The concept of 'free space' receives detailed consideration in Part 2 For the benefit of the uninitiated, free space may be defined as that part of a cell or tissue into and through which solutes move readily by physical processes The authors have at various times separately suggested that cytoplasm forms part of the free space They now conclude that it can be adequately accommodated in water-filled spaces in and around the cell wall This is a return to the classical view—never relinquished by more conservative plant physiologists, who are unable to accept the idea of cytoplasm being freely accessible to the vicissitudes of the environment The possibility that a small but more interesting fraction of the free space may be associated with the cytoplasm is still not excluded, but adequate evidence is lacking

Part 3 is concerned with the active absorption of salts and its connexion with metabolism The principles of an ion-carrier mechanism are set out, and a general scheme linking anion transport to electron flow is outlined. Cation movement is said to occur passively along an electro-chemical potential gradient established by anion movements No explanation is offered for the active extrusion of sodium ions which occurs in some algae and in yeast It is surprising that Conway's 'redox pump' is not mentioned in this context since it seems to differ fundamentally from the mechanism proposed only in that it is designed to transport cations rather than anions Presumably in the authors' minds yeast is not looked on as a respectable plant cell, but surely it is unwise to confine one's attention narrowly in discussing such a fundamental biological process as ion-transport

In a short final section, some aspects of salt absorption and transport in organs and intact vascular plants are reviewed It is evident that adequate understanding of these processes which involve yet another level of complexity must await further knowledge of ion movements at the cellular and sub-cellular levels JAMES F SUTCLIFFE

ORCHIDS OF TRINIDAD AND TOBAGO

Native Orchids of Trinidad and Tobago

By Dr. Richard Evans Schultes (International Series of Monographs on Pure and Applied Biology Division Botany, Vol 3) Pp x+275+21 plates. (London and New York Pergamon Press, 1960) 100*s* net

THE third volume in the Pergamon Press's Botanical Division of its new series of Biological Monographs endeavours to maintain the standards set by the two previous volumes of Dr Turrill and Dr Bor on general botany and Indian grasses respectively

Constituting the second largest plant family in Trinidad and Tobago the 180 species of Orchidaceae occurring there merit an account The continued use of Trinidad as an exporting centre for American plants, combined with the fact that so many of its orchids are at the same time beautiful, horticulturally amenable and scientifically interesting, doubly merits an account of the colony's orchids This was realized long ago, and Grisebach (1864), Cogniaux (1910), Broadway (1918–32) and Wilson (1925) all published accounts of the species of the area, but it has been left to Dr Schultes to produce this comprehensive account dealing with Trinidad and Tobago only The classical Flora style that he adopts is admirably suited to the needs of present-day botanists, growers and collectors

The first pages are concerned with a general treatise on the orchids followed by a historical account of collecting in Trinidad and Tobago and the subsequent research There are dichotomous keys to all genera and species, and constant usage during the past few weeks has shown these to be as useful and accurate for determining pressed specimens as for living plants

The main text is composed of a description of each genus followed by a specific key and the descriptions and synonymy of each species The arrangement of genera follows that of Schlechter, which most herbaria nowadays adopt To have the genera grouped according to their 'affinities' is obviously of great use, but, unfortunately, the arrangement of species follows the same rule as in other recent American Floras, that is, alphabetical Affinities between species are therefore not indicated and this can be disastrous when attempting to identify species of a critical nature especially when the keys are also avowedly artificial The species are numbered, but this is quite pointless as the numbers follow the alphabetical sequence

Taxonomic science is a matter of opinion and no criticism should be levelled at Schultes concepts, but nomenclature and phytogeography are more absolute sciences and it is in the interests of all that a few errors be mentioned

The Jack Spaniard, a commonly cultivated species, is named (p 180) as *Gongora maculata*, but this should be *G. quinquenervis*, a name published for this entity thirty-five years before *G maculata*. as indeed the author states in his synonymy *Stanhopea grandiflora* (p 177) is an incorrect name as the epithet *grandiflora* was not published in Loddiges' *Botanical Cabinet*, which was just a book of coloured plates with none of the descriptions or dissections necessary for validation of the names The correct name is *Stanhopea eburnea*, this epithet being published earlier than the validation of *grandiflora* A much more complicated case is that of *Polystachya luteola* (p 154), correctly *P extinctoria* (for a full discussion of this see *Taxon*, 9, No 5, 150, 1960)

A more serious misleading mistake is that the term *ex* is erroneously used Its use is reserved as a conjunction linking the authors' names when the later author published an earlier author's manuscript name In his citation of *Maxillaria liparophylla* (p 210) Schultes authorizes it with Summerhayes *ex* Sandwith, whereas it should be Summerhayes *in* Sandwith Sandwith did not take up an unpublished name of Summerhayes but Summerhayes actually published the name in a general account by Sandwith

A common misconception in the United States is perpetuated in page 162 concerning *Eulophia alta* being introduced into Africa from America Its widespread distribution in Africa suggests that this is impossible and that this species should join the list of those common to the Old and New Worlds

The book is typographically well produced and well printed on a white paper that does credit to the most excellent line-drawings selected from the archives of the Oakes Ames Orchid Herbarium at Harvard Species representative of most genera are illustrated by the pens of such artists as Elmer Smith, Gordon Dillon, G C K Dunsterville, Blanche Ames and many others, and although they have all appeared in previous publications this in no way distracts from their utilization here

It is unfortunate that photographs were used so obviously as an afterthought, probably under the erroneous impression prevalent to-day that photographs boost sales Good photographs of well-selected species probably would help the publication, but poor photographs, ill chosen (of species already amply illustrated by the line drawings) as are those in this book, increase the price but detract from the value The photographs are of no conceivable æsthetic or scientific value whatsoever

In all fairness the book does enable one to achieve the prime object of a Flora—to identify plants , but just a little more care and thought would have rendered it so much more useful

P Francis Hunt

ECOLOGICAL BRANCH OF RUSSIAN PARASITOLOGY

Parasitology of Fishes

By V. A Dogiel, G K Petrushevski and Yu I Polyanski Translated by Dr Z Kabata Pp x + 384 (Edinburgh and London Oliver and Boyd, Ltd , 1961) 84*s* net

THIS book was inspired by the wish of Valentin Alexandrovich Dogiel to institute collective discussion of theoretical and practical problems involved in the parasitology of fishes Wearied by lists and descriptions of new species, he yearned for knowledge about the whole life of the parasitic fauna which he foresaw as a weapon in the fight against parasitic diseases In 1927 he founded this ecological branch of Soviet parasitology and in 1930 the parasites of fishes became a priority study The vast territory of the U S S R comprises most of the habitats of fishes which exist on the Earth, and ultimately all the main rivers, most of the large lakes and both internal and bordering seas were being examined in great parasitological detail He wrote the first chapter of this book himself, and most of the others were written with his guidance Regrettably, he died on June 1, 1955, but in 1958 his wish was to some extent fulfilled when the Russian original of this book was published

Dogiel recognized the prime peculiarity of the parasite, that its environment is furnished by another living organism, the host I do not believe that his choice of fishes as hosts was accidental, because this is the most ancient class of the vertebrates and it harbours more parasites than does any other class Moreover, fishes are important in relation to food supply, and in this book we can recognize a great urge to implement research for economic reasons Dogiel's study of the dynamics of assemblages of parasites inhabiting one host ('parasitocœnoses') convinced him that the environment of the parasite comprises the host (the micro-environment) and the habitat of the host (the macro-environment) The composition of the parasitic fauna of fishes depends on changes in the habitat of the host and changes in the physiological states of the host Geographical location, the season of the year, characteristics of water and bottom in rivers, lakes and the sea, related organisms in and around the habitat, and many other biotic and abiotic features of the environment provide the means of life for host and parasites alike The composition of the parasitic fauna is determined also by the nature of the food and digestive equipment of the host, and other influential factors are age, general condition as indicated by states of nutrition or inanition times of spawning, migration, hibernation and even speeds of locomotion The nature of the integument of the host and its secretions influence parasites which penetrate the skin, some of which are parasites of man Many patterns of correlated environmental factors fluctuate periodically and modify the composition of the parasitic fauna

Dogiel's influence is seen in various chapters of the book dealing with such topics as the ecology of parasites of marine and freshwater fishes, questions concerning host-parasite relationships, specificity, life-cycles and zoogeography Some consideration is given to the parasites of fishes living in reservoirs, changes in the parasitic fauna of acclimatized fishes, parasitic diseases of fishes living in natural waters and also cultured fishes, and fishes as transmitters of human helminthic disease The parasites considered are mainly Protozoa, Platyhelminthes, Nematoda, Acanthocephala and Copepoda Many isolated observations provide interesting revelations but extensive regional surveys may give the specialist more satisfaction The format is pleasing, the translation is readable, and the text is illustrated with diagrams and maps and supplemented by comprehensive tables More than 700 references to the original literature are cited, nearly two-thirds of them from the Russian Errors are few and mainly typographical but sometimes surprising the statement on p 105, "Monogenoideans with a single host", refers to several digenetic trematodes but no monogenetic forms

Students and teachers will find in the book a fund of readily assimilable information, and if the appetite of the specialist is sometimes unsatisfied the gaps more often than not indicate the opportunities for research workers in the future All concerned with the production of the book deserve credit for giving biologists this opportunity to evaluate Russian progress in a branch of parasitology which has been neglected in Britain BEN DAWES

SALT MARSHES AND SALT DESERTS

Salt Marshes and Salt Deserts of the World

By Prof V J Chapman (Plant Science Monographs) Pp xvi + 392 + 45 plates (London Leonard Hill (Books), Ltd , New York Interscience Publishers, Inc , 1960) 95*s* net

LET the good things be placed on record first This book brings together a wealth of information from widely scattered and often inaccessible sources and illuminates it with the author's own long experience of salt marshes Any student undertaking work in this field in the future will certainly start by "looking it up in Chapman" For this service all botanists will be grateful, but gratitude need not blind us to the book's many faults, nor will it arm the struggling reader against exasperation For the book is, frankly, not so much written as thrown together

It opens inauspiciously with a chapter which hovers uneasily between a statement of intentions and a summary of findings This is followed by three chapters on general features of the habitat, the chief fault of which is that they are insufficiently general, all too often a promising principle collapses into a detailed study of a specific example In the next five chapters we are taken on a conducted tour of the salt marshes of the world, and here the author is at his best, we realize that information about the different areas will be uneven, and presentation of these scattered and largely unrelated data is congenial to the author's discursive style Elaborate and detailed successional schemes are, however, given with an off-hand confidence which is likely to arouse misgivings Finally, there are three miscellaneous chapters The first of these summarizes the author's own views on the successions and phytosociological entities represented, and these are most welcome, but the chapter continues with a quantitative study of the affinities between communities which suggests that the author is unaware of the difficulties in devising and interpreting parameters suitable for this type of comparison The chapter ends, unaccountably, with a brief account of salt-marsh fucoids Then follows a disastrous chapter on "Physiology of Halophytes", in which the whole of the thinking concerning transpiration is out of date, and the statements concerning ion uptake simply fail to make sense The book ends with a brief but interesting account of economic uses

It is all clearly the work of a man passionately devoted to his subject, avidly and uncritically welcoming any scrap of information which comes his way, but still too involved in minutiæ to discern underlying patterns If Prof Chapman, secure in his remarkable knowledge, had brooded over his information for a year or two, and then written, and re-written, and revised, he might have given us a new classic, as it is, botanists can only weep for what might have been and go and buy the book W T WILLIAMS

MICROSCOPY IN A MAZE

The Encyclopedia of Microscopy

Edited by Prof George L Clark Pp xiii + 693 (New York Reinhold Publishing Corporation, London Chapman and Hall, Ltd , 1961) 200*s* net

THIS is not an encyclopædia in the ordinary sense, but a collection of 140 articles There is no index, and the subject titles are not always helpful It is thus very difficult to look up any specific point The articles are strung together with little correlation or cross-reference, leading to useless repetition or omission of important topics The two articles on interference microscopy cover much common ground and contain several similar diagrams, but no adequate discussion of phase contrast is to be found There is a good article on the design of the polarizing microscope for detecting very weak birefringence, but no proper description of the basic instrument or its use in crystallography Fluorescence microscopy is represented by two pages from a commercial brochure Fluorescence labelling of proteins, which has led to one of the most important advances in modern biological microscopy, is not mentioned

The section on ultra-violet microscopy contains three pages on methods, with almost no discussion of results or applications, one page on colour translating television systems (with no references) and more than nine pages on "Image Formation by a Fresnel Zone Plate" The latter article might find a place as an original paper in a specialist journal, but why it was given so much space when so little was devoted to ultra-violet microscopy itself is a complete mystery

This lack of balance and bad choice of material is seen throughout the book There is virtually no discussion of resolving power, no description of light sources, no section on photomicrography, yet 30 pages are devoted to non-microscopic refractometry This section is remarkable, for although it includes descriptions of many refractometers and interferometers, it contains not a single diagram of any sort Electron microscopy is equally unbalanced Biological microscopy has been revolutionized by new methods of fixation, embedding and ultra-thin sectioning, but the article on specimen preparation deals only with special non-biological methods used at Los Alamos Such an omission can only be described as fantastic.

The choice of biological subjects is quite extraordinary Thirteen pages are devoted to "kidney ultrastructure", but this is the only organ dealt with Why kidney ? Why not liver, glands, digestive or nervous systems, for example ? One turns to the heading "Pathology" in the hope of reading a much-needed general article on the use of electron microscopy in this field, only to find that another thirteen pages are devoted entirely to the kidney Unfortunately, one could go on writing in this vein for quite a long time Any book of 700 pages is likely to contain some useful information, but it is a pity to see so much effort wasted by bad editing and poor selection of material R Barer

STUDIES IN ENDOCRINOLOGY

Études d'Endocrinologie

Séminaires 1960 de la Chaire de Morphologie Expérimentale et Endocrinologie du Collège de France dirigés par le Professeur Robert Courrier. (Actualités Scientifiques et Industrielles, No 1286) Pp xiv + 350 (Paris Hermann, 1961) n p.

SINCE 1959 some of the advanced courses of lectures which it has long been the tradition for professors of the Collège de France to deliver have been replaced by public seminars at which eminent research workers are invited to discuss the results of their studies The records of two such occasions, both arranged by the Department of Experimental Morphology and Endocrinology, have now appeared

The first deals with the gonadotrophins, and was organized jointly by Prof Robert Courrier and Dr Marian Jutisz The published proceedings provide an up-to-date account of the various gonad-stimulating hormones which can be extracted from pituitary tissue, from the urine of pregnant women, from human urine after the menopause, and from the blood serum of pregnant mares An account is also given of the relationship of sheep pituitary prolactin to other gonadotrophins The papers which describe these various hormonal substances are published in full, with a record of the discussion which followed each day's presentation Four general papers concluded the seminar, and each raises some issue of wide importance The first, by Prof Max Aron, takes up the much-debated question of the degree to which, both qualitatively and quantitatively, luteinizing and follicle-stimulating hormones are distinct hormones The experiments on the guinea pig which he reports tend to indicate that as entities they are not as separate as is usually taught Dr Robert Henry's contribution on the biological dosage of hypophysial gonadotrophins leads to a contrary view, however, with respect to follicle-stimulating hormone and interstitial cell-stimulating hormone, and the paper by Dr Pierre Aschheim—the son of the Aschheim whose name is associated with that of Zondek in the discovery of human chorionic gonadotrophin—also supports the view of the separate chemical identity of various gonadotrophins In the general discussion following the presentation of these papers, follicle-stimulating hormone, interstitial cell-stimulating hormone, the post-menopausal urinary gonadotrophin of women as well as pregnant mare serum were, none the less, set aside as substances which had not yet been isolated in a state of sufficient purity to be regarded as chemically separate Human chorionic gonadotrophin and prolactin, on the other hand, seem to satisfy the criteria of chemical purity, although it was made plain that the criteria of purity are themselves arbitrary

The broad conclusion which emerges from the whole discussion is that much more work will need to be done before we can expect to understand the underlying chemistry of the reactions of the ovaries and testes to the numerous gonadotrophic preparations which the biochemist has already isolated Of facts about gonadotrophins we have plenty, what we lack is an underlying hypothesis which strings them together

The second part of the volume records a seminar arranged by Dr Roger Guillemin on the functional relations of the hypothalamus to the adenohypophysis, with particular reference to the release of adrenocorticotrophic hormone In this field of research the facts, while also numerous, seem somewhat more untidy than those which were dealt with in the first seminar—while of hypotheses there is not a single one which is not characterized more by empty speculation than by predictive value

The opening paper in this symposium was by Prof André Delmas, and dealt with the anatomy of the hypothalamus and its connexions Prof Delmas was followed by Dr Henri Duvernoy, who reported a series of observations on the vascular connexions between the adenohypophysis, the neurohypophysis and the median eminence Contrary to the fashionable belief that has been so assiduously disseminated in recent years, it is now clear that the vascular system of the anterior pituitary connects freely not only with the pituitary portal vessels, but also with the vessels of the neurohypophysis and, through the portal vessels, with those of the hypothalamus This observation is a further nail in the coffin of the theory, based on 'negative' observations, that the pituitary portal vessels form a unique connexion between the hypothalamus and the anterior pituitary, and that through them passes some chemical mediator of hypothalamic origin which stimulates the anterior pituitary to release its various hormones as demanded by the physiological state of the body Dr Duvernoy's new data make it plain that any chemical mediators which the hypothalamus might produce and which enter the pituitary portal vessels could reach the posterior pituitary as well as the anterior pituitary and if any local hormonal action were involved in the control of the anterior pituitary, there is no reason for supposing that there is any physical barrier to the passage of substances in whatever direction one cares to suppose But all this is pure speculation

The second symposium also dealt with the technique of measuring changes in the level of secretion and action of adrenocorticotrophic hormone, as well as with the variety of nervous stimulations which leads to the discharge of adrenocorticotrophic hormone The evidence in favour of the alternative views that the release of adrenocorticotrophic hormone is mediated by some neurohumoral substance of unknown chemical nature (the so-called CRF) or by vasopressin, or by melanophore-stimulating hormone, was reviewed by Dr Guillemin, but there seems little that is precise about these matters, and as the general discussion at the end of the seminar indicated, considerable doubt exists about the assumed localization of hypothalamic function with respect to the control of pituitary function.

The verbatim record of what passes at endocrinological symposia has on occasion detracted from the value of what might otherwise have been regarded as scientific meetings of high quality On this occasion this is not so Not only do the papers which were delivered at the seminars of the Collège de France provide a first-rate account of the matters with which they deal, but it is also plain from the record of the discussions that Prof Courrier kept the several sessions of the two seminars very much to the point He is to be congratulated for having inaugurated a series of seminars which will, one is certain, continue to enjoy the high standard of the two now published S ZUCKERMAN

HÆMOGLOBIN: NORMAL AND ABNORMAL

Hemaglobin and Its Abnormalities

By Prof Vernon M Ingram (A Monograph in American Lectures in Living Chemistry) Pp. xiv + 153 (Springfield, Ill Charles C Thomas, Oxford Blackwell Scientific Publications, 1961) 60*s*

HÆMOGLOBIN is the most intensively studied of proteins Many of the techniques available to the physiologist, biochemist, biophysicist and geneticist have at one time or another been applied to hæmoglobin All this work has led to spectacular progress in our understanding of the structure and function of hæmoglobin and its near relative, myoglobin

Last year saw the publication of papers that represent the culmination of long and detailed analysis by the investigators concerned Kendrew and his colleagues have extended the resolution of data from their X-ray diffraction patterns of myoglobin to the 2 Å -level, so that for the first time the helical arrangement in the polypeptide chain of a protein can be unequivocally demonstrated At the same time, Perutz *et al* published the structure of hæmoglobin at a resolution of 5 5 Å Because of its very great similarity to the myoglobin structure, they have been able to infer considerably more than the actual resolution allows From these X-ray diffraction patterns detailed information about the secondary and tertiary structure of proteins in crystalline form can be deduced There is already correlation of structures deduced from X-ray patterns with the amino-acid sequences which are now known for the human hæmoglobin chains and nearly all known for horse hæmoglobin chains and myoglobin

In 1949, Pauling *et al* demonstrated that the basic defect in sickle-cell disease is an abnormal hæmoglobin The term 'molecular disease' introduced by Pauling for conditions of this kind has caught the imagination of many research workers and provided a great stimulus to research in the field Eight years later Ingram applied Sanger's technique of peptide analysis to normal adult and sickle-cell hæmoglobins. He found that the two molecules differ only in a single peptide, and later this difference was shown to be due to the substitution of the amino-acid valine for glutamic acid which occupies the sixth position from the amino-terminus of the β-polypeptide chain of the normal molecule Ingram and his co-workers, and later others, have shown that several other abnormal hæmoglobins differ from the normal by single amino-acid substitutions in the β- or α-chain There was formal evidence that genes controlling the synthesis of normal and abnormal β-chains were allelic with one another but not with genes controlling synthesis of α-chains

Ingram's important discovery could not have come at a more opportune time The importance of proteins in mediating genetic effects transmitted by nucleic acid had emerged from the publications of Crick and others, and there was a great need to know the sort of effects on protein structure produced by mutation of the genes controlling their synthesis The studies of Ingram and his colleagues provided precisely the required information The technique of peptide analysis, re-named by Ingram 'fingerprinting', came to be used in many laboratories for establishing exact structural differences between related proteins

In the book under review Ingram gives a general account of these developments, beginning with the structure and function of the normal hæmoglobin molecule and describing the structural differences in some of the known abnormal molecules The arguments are well presented and easy to read. There are few mistakes (in caption 2 to Fig 46 *S* should be replaced by *F*) Diagrams and references have been carefully selected and provide an excellent introduction to the field So much has been done that it is, of course, impossible to expect a book of this length to serve as a comprehensive reference work Although the main emphasis of the book is biochemical, the diseases associated with the abnormal hæmoglobins are briefly discussed and a few of the interesting problems in population genetics raised by the high frequency of certain abnormal hæmoglobin genes in some human populations are mentioned In connexion with the latter, Ingram quotes the extraordinary and unfounded suggestion that "hæmoglobin E might have a selective advantage because in the presence of this gene the likelihood of an allelic thalassæmia disease occurring in homozygous form is removed"

This book is likely to be read by many people with an interest in biochemistry and genetics, and it seems a pity that, although only 150 pages long, it should cost £3 A C ALLISON

ADVANCED ORGANIC CHEMISTRY

Advanced Organic Chemistry

By Prof G W Wheland Third edition Pp xi + 871 (New York and London John Wiley and Sons, Inc , 1960) 17 50 dollars, 140*s*

THIS book constitutes an extended, revised edition of Prof G W Wheland's well-known book, *Theoretical Organic Chemistry*, which, for more than a decade, has been of such considerable value to both university students and lecturers The new edition has been well produced with most legible printing on good quality paper and the spatial and conventional organic chemistry formulations are reproduced with considerable clarity

The historical approach employed throughout the text is thought-stimulating and interesting, the earlier chapters dealing with the general theories of valency bonding, inter-atomic force theories, etc Electrostatic, covalent, semipolar double bond systems, etc, are clearly described, together with valuable excursions into the fields of dipole–dipole interactions, solvated chains, polarization and orientation phenomena. The first chapter, on valency and configuration, forms a natural precursor to discussions on the determination of structure by various physical methods, and general comment is made on the application of nuclear magnetic resonance, rotatory dispersion and parachor applications

Other chapters deal with the Lowry–Brønsted theory of acids and bases, and the allied Lewis concept, a survey is made of clathrate inclusion compounds, of nucleophilic displacements, S_N and their relation to S_N1 kinetics and to S_N2 reactions of the Walden inversion type

A most extensive chapter deals with the stereochemistry of carbon, which is well illustrated with numerous examples illustrating resolution, solvent effects, configuration studies, optical phenomena, etc This is supplemented by a further chapter on stereochemistry of elements other than carbon, notably those of nitrogen and sulphur Free radical chemistry also receives the most detailed treatment

The Baeyer strain theory, steric hindrance and conformational analysis receive much attention A memorandum by Prof F W Westheimer on electrostatic affects in organic chemistry forms the basis of Chapter 11, which concludes with a rather abbreviated discussion of the Hammett rho-sigma relations References are, however, given to H H Jaffe's excellent review of this quantitative empirical relation between the rate or equilibrium constants of reactions involving organic compounds The value of kinetic data is frequently stressed throughout the book, and in all chapters the mathematical treatment is of reasonably simple character and will not prove over-burdensome to those who find the more abstruse mathematical concepts somewhat difficult to follow

This book is an able successor to its authoritative predecessors, and will do much to stimulate original thought and constructive discussion in the ever-extending and complex field of theoretical organic chemistry D T Lewis

TEXT-BOOK OF INORGANIC CHEMICAL ANALYSIS

Quantitative Inorganic Analysis

By Prof R Belcher and Dr A J Nutten Second edition Pp x+390 (London Butterworths Scientific Publications, 1960) 35*s*

It is highly commendable that the authors have so thoroughly revised a text-book that is only six years old Among the novel features introduced are choice of appropriate redox indicators for particular systems, and criticism of uncertainties involved in the dichromate–ferrous reaction It is a pleasure to see classical gravimetric analysis treated with due respect and yet a pity to miss a reference, presumably due to shortage of space, to the solvent extraction technique

The reviewer disagrees with the condemnation of the swinging-point balance In its simplicity and versatility, especially as regards control of sensitivity, it ought to remain for a long time a basic instrument in the hands of a chemist Some minor criticisms may be mentioned briefly Cleaning of pipettes by immersing overnight in a dichromate–sulphuric acid mixture is in the long run detrimental to the pipette inscription On p 150, it is pointed out categorically that laboratory glassware should on no account be warmed which, without defining temperature limits or stating reasons, sounds very dogmatic On the other hand, the temperature control in a drying oven to within ± 1° C (p 10) seems exceptionally good for an average student drying oven In the volumetric section, the conventional ferric alum is recommended as indicator in Volhard's method, while in the colorimetric section the authors state that sulphate ions tend to form complexes with iron(III) Why not propose ferric nitrate as indicator in the first instance ?

The book has been edited with great care and the occurrence of misprints such as that in the legend to Fig 40 is exceptional

This clear, concise, and up-to-date text-book can be whole-heartedly recommended for use by students and practising chemists G Kakabadse

THE POLYNUCLEOTIDE FIELD

Polynucleotides

Natural and Synthetic Nucleic Acids By Robert F Steiner and Roland F Beers, Jr Pp viii+404 (Amsterdam Elsevier Publishing Company, London D Van Nostrand Company, Ltd, 1961) 85*s*

In the introductory chapter of this monograph, the authors point out that the nucleic acid and associated fields have expanded at such a remarkable rate in the post-war years that it is no longer possible to attempt a complete coverage of them in a single text They go on to list a few of the main subdivisions such as chemical genetics, virus biochemistry, protein synthesis, polynucleotide synthesis and the physical chemistry of polynucleotides The extensive developments in the last two subdivisions in the five-year period ending 1960 have prompted Dr Steiner and Dr Beers to write this book In the final chapter they touch on some of the other main subdivisions by discussing the biological roles of nucleic acids

The introduction, which indicates the scope of the book, is followed by a chapter on the organic chemistry of nucleotides Then the chemical and enzymatic evidence for the nature of the inter-nucleotide linkages in ribonucleic acid, deoxyribonucleic acid and synthetic polynucleotides is discussed This is followed by two chapters on nucleotide-polymerizing enzymes In the first, a description of the procedures for isolating and assaying these enzymes is given, and in the second, the properties of the different enzymes are discussed The next three chapters deal with some physical methods such as ultra-violet spectroscopy, optical rotation and X-ray diffraction, and their application to the determination of the macro-molecular configuration of natural and synthetic polynucleotides The final chapter, mentioned above, is preceded by a discussion of the helix-coil transition and the binding properties of polynucleotides Besides the main text are included some seventeen appendixes which outline the experimental procedures for the isolation of nucleic acids and the analysis of their degradation products, and for the preparation, assay and use of some nucleotide-polymerizing enzymes

The authors are certainly justified in writing a book on a subdivision of the nucleic acid field as no one or two people could possibly review every aspect of the subject critically Such is the scope of this book that, if anything, they have tried to cope with too much for two people, although it is certainly very useful for workers in the polynucleotide field to have all this material collected in one volume For the latter reason, Dr Steiner and Dr Beers are to be thanked for sorting out such a vast amount of the present-day literature

However, it might have been wiser for the authors to have co-opted specialists to write the chemical chapter in the beginning of the book and help with the accounts of some of the other areas to which they themselves do not appear to have contributed I would single out the chapter on the chemistry of the nucleotides for the greatest criticism This contains formula, chemical, and factual errors and some important omissions, but it is nevertheless an adequate account of this aspect Perhaps the only other adverse criticism of this very useful book is that it is not always written in a clear and concise style The appendixes are a good idea and should be useful The printing and layout are good with the exception of some of the chemical formulæ On the whole, this book can be recommended as being of considerable value to workers in the polynucleotide field, for whom it is designed, and to other people interested in this important subject C B Reese

TECHNOLOGY OF ETHYLENE POLYMERS

Polythene

The Technology and Uses of Ethylene Polymers Edited by A Renfrew and Philip Morgan. Second edition Pp xxi + 781 + 93 plates (London Iliffe and Sons, Ltd , New York Interscience Publishers, Inc , 1960) 165*s* net

THE growth of polythene production has been one of the major features of the plastics industry in recent years The interest aroused by the development of newer types of polythene and the many recent technological developments in the field of ethylene polymers have necessitated a considerable revision of the text of this well-known book The present edition—the second—contains approximately 300 more pages than the previous one , chapters have been so revised that the original text has been largely re-written in order to bring the book in line with rapid developments, particularly in relation to materials of higher density In fact, it has been so changed and enlarged that it may be regarded as virtually a new book

The most important additions are as follows The chapter "Manufacturing Processes" now appears as four contributions describing high-pressure, Zeigler, Phillips, and Standard Oil Co polymerization processes , the chapter on the theory and mechanism of ethylene polymerization now becomes two chapters to cover, respectively, polymerization by free radicals and by ionic growth Additional chapters are "Ethylene Copolymers and Polymer Blends", "Vacuum Forming", "Reprocessing" and two chapters on packaging which describe those varied and useful applications not classified as films Valuable appendixes are a table of world manufacturers of polythene and their production capacities, and a list of world proprietary names for ethylene polymers

The thirty-six chapters of this book deal with every aspect of polythene, its manufacture and properties (structure, mechanical, electrical, chemical, testing, radiation treatment, and modification) , processing techniques (compounding, pigmentation, extrusion as applied to extruder design, cable covering, tube, rod and profile, film and sheet, injection and blow moulding, centrifugal cast, coating and laminating, dip and spray coating, vacuum forming and reprocessing), and applications (cables, film, coated packaging products, pipes, chemical plant, household goods, textile yarns and fibres) Each of the chapters, written by an expert either from Europe or the United States, provides a most complete and authoritative account of the technology and uses of this important polymer The book remains the standard work on the subject C E H Bawn

GAS DYNAMICS IN THE U.S.S.R.

Physical Gas Dynamics

Edited by A S Predvoditelev Translated from the Russian by Dr R C Murray and D R H Phillips Pp v + 183. (London and New York Pergamon Press, 1961) 50*s* net

THIS book is a translation from the Russian of a symposium of twelve papers covering a wide range of topics under the general heading of the title

Five of the papers cover the field of gas kinetics, the longest being concerned with calculating the properties of air in the temperature-range 1,000° K – 12,000° K , and the pressure-range 0 001–1,000 atmospheres Two of the other papers calculate the changes across normal shock-waves in air considered as a real gas

The next two papers consider experimentally the supersonic flow at an oblique-cut nozzle and an oblique-cut base. These are related to the flow in turbine nozzles and blades

The next three papers again present a sharp contrast, the subject under discussion being the pressure field resulting from electrical discharges under water, while the last two papers in the book discuss shock waves associated with flames Four of these five papers discuss experimental work

One of the difficulties encountered by publishers of a book of this nature is that of making the information available sufficiently quickly after completion of the work on which it is based The references to the various papers indicate that most of the work presented at the symposium was done prior to about 1956, so in this sense the book is not up to date, but, despite this, there is no doubt that it gives some of the most up-to-date information in English on the work being carried out in the U S.S R in the field of gas dynamics

It is fair to say that the translation into technical English is in general excellent, though it is noted that in some references which were originally in English, but have been translated into Russian, the authors' names are not correctly translated back into English. The printing is in non-letterpress type setting, but this in no way detracts from the book, perhaps the only thing which does being the quality of schlieren photographs on which several of the papers depend The photographs are in general poor, but there is no indication whether this is due to the printing process used or to the poor quality of the originals

I S Donaldson

SURVEY OF ASTRONOMY

Vistas in Astronomy

Edited by Arthur Beer Vol 3, Part 1 Dynamics—Geophysics—Instruments—Solar System Vol 3, Part 2 Stellar Astronomy—Stellar Evolution—Photometry—Galaxies—Spectroscopy—Cosmology (Special Supplement No 7 to the *Journal of Atmospheric and Terrestrial Physics*) Pp vii + 345 (London and New York Pergamon Press, 1960) 120*s* net

The third volume of *Vistas in Astronomy*, published, as in the case of the two preceding volumes, by Arthur Beer, opens with an article by R. van der R Woolley, Astronomer Royal, on "The Dynamics of Stars in the Neighbourhood of the Sun" The author deals in particular with the movements of stars near at hand, the permanence of very open clusters and the equipartition of energy R A. Lyttleton poses the following question "What is the simplest theoretical approach and minimum amount of calculation that could have led to the discovery of the planet Neptune ?" Tisserand had already posed this question in his *Mécanique Céleste*, when he suggested that it would suffice to assign successive values to the radius of the planet. which is supposed to have a circular orbit Lyttleton shows that one can simplify the problem considerably without altering the numerical solution much, by attributing circular orbits to both Uranus and Neptune The position which he finds for the hypothetical planet does not differ more than one degree from the observed position, as for its mass, he approximates the real value more closely than Adams and Le Verrier But he has the advantage over his two predecessors of knowing that Neptune exists, whereas in 1845 or 1846 it was doubtful, as the question posed by Airy to Adams at first and then to Le Verrier proves What is more, we know that the orbit of Neptune has a slight eccentricity The paths of discovery are often tortuous, but one does not perceive this until the goal has been attained

The contribution of H von Kluber is also of great interest and of more immediate application It is a discussion which takes into account all the determinations, made since 1919, of the displacement of stars around the Sun when in eclipse The existence of this effect is not in question, but the extent of displacement remains very uncertain It appears, however, to be greater than that provided by theory The observations are very scattered and, in consequence, the hyperbolical variation of the displacement as a function of the distance from the Sun cannot be considered as established The recommendations directed by H von Kluber to future observers must be acclaimed without reserve

Of interest are articles, one by W Cochran, the other by V Fock, on "The Clock Paradox", some studies by G M Sisson on the "Design of Large Telescopes", by Marschal A Wrubel on "The Electronic Computer as an Astronomical Instrument", by A H Jarrett on "Techniques in Auroral Investigations" and by D W Beggs on "The Russian Satellites" Finally, four notes on the brilliant comets of 1957 complete the first part of this volume

John B Irwin opens the second part with an article entitled "The First 70,000". It is the exposition of a vast programme of observations destined to yield the following for all stars down to magnitude 8 5 position, proper motion, magnitude, multicolours, spectral type, luminosity, parallax, radial velocity and polarization. The author emphasizes, by an apt title, the paucity of information we have on the southern hemisphere He discusses the use of the transit circle for the determination of positions and proper motions, but he does not mention the use of the impersonal astrolabe for establishing the fundamental catalogue Altogether, the programme outlined by John B Irwin is excellent, but only international co-operation will allow it to be executed It would be an interesting task for the International Astronomical Union

Modern aspects of stellar photometry are dealt with in two articles, one by Gerald E Kron on "Multiple Colour Photometry", the other by A N Argue entitled "Photometry with the Cambridge Schmidt Telescope" A long study by B E J. Pagel provides interesting ideas on "The Excitation of Emission Lines in the Spectra of Early-type Stars".

Olin J Eggen has prefaced his article, "Colour, Luminosity and Evolution of the Stars", with some opinions of this evolution by celebrated men of science, from Helmholtz (1854) to Eddington (1926). This comparison of ideas put forward by very high authorities produces an effect of shock on the reader of to-day and inspires him to salutary reflexions on what H Poincaré called "La Valeur de la Science" Eggen shows, with diverse examples, all that photometry of stellar clusters in several colours teaches us about stellar evolution The volume ends with a representation of "The Visual Milky Way" by Sergei Gaposchkin and with two theoretical studies, one by L Mestel entitled "Star Formation and the Galactic Magnetic Field" and another by D. W. Sciama called "Observational Aspects of Cosmology".

Presented with the same care as the two preceding ones, Volume 3 of *Vistas in Astronomy* contains an abundant bibliography and a very detailed "Name and Subject Index", it is an excellent piece of work. The editor announces the publication of two other volumes, the authors of which will be drawn from fifteen countries or so *Vistas in Astronomy* is indeed of immense utility for all those who wish to know the state of advancement of the diverse branches of astronomy.

THE NATURAL HISTORY OF GALAXIES

The Hubble Atlas of Galaxies

By Allan Sandage Pp viii + 32 + 50 plates. (Washington, D C Carnegie Institution of Washington, 1961) 10 dollars

This is a remarkable and fascinating book. Conceived by Edwin Hubble, who did not live to see it finished, and now completed by Hubble's pupil and successor, Dr Allan Sandage, it can be recommended to a very wide range of readers, from mature specialists in cosmology to young people with a good sense of curiosity and wonder It consists of reproductions of photographs of 176 galaxies, taken almost entirely with the large reflectors of the Mount Wilson and Palomar Observatories, and many made by Hubble himself The photographs are of the highest technical quality and are unlikely to be surpassed until we learn to build much better telescopes, or invent new techniques, perhaps involving artificial satellites Although reproduction is by a half-tone process, such care has been taken that one can often see detail down to about 1 second of arc in diameter In a number of cases two, or even three, prints are given, since the range of surface brightness is too great for one print to show all structure of interest

A preface describes the origin of the *Atlas* and this is followed by a chapter entitled "Galaxies", giving a summary of immediately relevant information, including some very instructive, and sometimes amusing, history that ought to be compulsory reading for all astronomers This is followed by a long and detailed description of Hubble's system of classification, which the *Atlas* was designed to illustrate, with frequent references to individual photographs. Besides this, each photograph is provided with its own commentary, usually about 100 words but sometimes considerably more.

If we exclude clusters of galaxies and the universe itself, galaxies are the largest physical structures known to man We believe them all to be aggregates of gas, dust and stars, of total masses mostly in the range 10^9–10^{11} Suns, and with rather ill-defined optical diameters of the order of 10^4–10^5 or more light years Hubble's system of classification, the simplest proposed so far and perhaps for most purposes the most useful, is a purely morphological one The outstanding characteristic of nearly all these objects is that their form strongly suggests rotation, and spectroscopic measurements confirm this Hubble arranged galaxies into an order which in general is one of increased flattening, increased development of spiral arms, diminishing nucleus, growing signs of interstellar dust, probably more interstellar gas, more resolution into stars and greater abundance of young, hot stars He was always careful to point out that his sequence is not necessarily one of evolution, in either direction Sandage follows him, but can add in the light of more recent work that, whether evolutionary or not, the sequence as just described appears to run from old to young

One criticism of Hubble's scheme has been that it may impose too simple an order on an essentially complicated problem. For other reasons too, having little to do with Hubble, most astronomers until fairly recently have tended to carry in their minds an altogether too regular and standardized picture of galaxies Fortunately, a better appreciation of the problem has been growing and now this *Atlas* makes it abundantly clear that galaxies, like most natural objects, are very far indeed from being simple, mass-produced structures Most of our respectable old friends are here, for example, *M*31, *M*33, *M*81, but so also are some much more awkward customers What of *NGC*520, 2685, 2859, 5128, or even the Large Magellanic Cloud ? What are we to make of the nuclei of four *Sc* spirals, here reproduced separately on a large scale, on page 31 ?

Hubble's original scheme, apart from a bifurcation between ordinary and barred spirals, is essentially one-dimensional But even on a purely morphological basis the quite limited sample of galaxies here cannot be fitted in neatly without qualification As Sandage remarks, "the classification sequence is not infinitely narrow perpendicular to the $Sa \rightarrow Sb \rightarrow Sc$ direction" Among *Sb* spirals, for example, he directs attention to variations in the size of the nucleus, in the thickness and surface brightness of the arms, and in the distribution of dust Some *Sb* galaxies have two sets of arms, of different pitch Among the *Sc* galaxies "at least six major sub-groups can be distinguished" Nevertheless, as a broad generality, a first approximation, Hubble's scheme still impresses one as valid

Although a mine of information, *The Hubble Atlas of Galaxies* is not a text-book Possibly the author should have emphasized this more in his preface It makes no pretence of dealing with the general problems of galaxies, of their dynamical structure, of their physical composition as revealed by the spectroscope, of their motions, of pairs of galaxies, multiple galaxies, colliding galaxies, linked galaxies, clusters of galaxies There is nothing of radio-astronomy, its results and its perplexities

There is also no discussion of the technical problems of photographing galaxies, the outer parts of which are much fainter than the natural sky background itself. (In these pictures the sky is reproduced nearly perfectly black, æsthetically satisfying but scientifically a little misleading) We are limited not by photographic speed but by sky brightness Equally, we cannot photograph detail less than about one second of arc, not because of the imperfections of telescopes and photographic emulsions, or their limited resolving power, but because of the optical irregularities of the Earth's atmosphere I think all this needs to be said clearly Observational astronomers take these familiar limitations for granted, but they are imperfectly understood by many others who may be users of this volume

What it comes to, of course, is that we need a full text-book on galaxies to accompany the *Atlas* Could Dr Sandage provide such a companion volume to give us instruction and pleasure in the same generous measure as does the *Atlas* itself ?

R. O REDMAN

THE HIDDEN FACE OF THE MOON

Atlas of the Other Side of the Moon

Edited by N P. Barabashov, A A. Mikhailov and Yu. N Lipskiy. Translated into English by Leon Ter-Oganian First published by the Academy of Sciences of the U S S R. Pp 141+30 photographs. (London and New York Pergamon Press, 1961) 50*s*

EVERYONE is familiar with the fact that the tidal friction operative in the Earth–Moon system has gradually slowed down the axial rotation of our satellite to the rate with which it revolves around Earth (the periods of these two motions being now synchronized within at least 0 1 sec)—which makes the Moon show us always the same face Lunar librations (both physical and optical) permit us, to be sure, to see from Earth somewhat more than one-half of the entire surface of the lunar globe—in fact, about 59 per cent of it—but the rest remained completely hidden to us, until the memorable flight of the third Russian space rocket in October 1959, which circumnavigated our satellite and by means of its photographic equipment carried aboard took at last the veil off its invisible face

The details of this feat are still sufficiently well remembered to require little repetition A preliminary report on the photographic data obtained in the course of this flight and televised afterwards to Earth was released by the U S S R Academy of Sciences in December 1959 (*First Photographs of the Far Side of the Moon,* the English translation of which was published by the Pergamon Press, London, in 1960), while a definitive discussion of the entire material followed a year later in a volume the English edition of which is under review

This volume summarizes the results of an exhaustive study of the topographic as well as photometric features of all available negatives, carried out independently at the Pulkovo Observatory, Sternberg State Astronomical Institute, Moscow, and the Kharkov Observatory, under the respective guidance of Profs A A Mikhailov, Yu N Lipskiy and N P Barabashov—all well-known students of the Moon The outcome of their impressive study (the methods of which are described in the first part of their book) resulted in the identification of 498 details on the lunar far side, the catalogue of which (classified according to their degree of reliability) constitutes the major part of the whole volume The formations discovered on the far side of the Moon do not, in general, differ from those we know on the visible face in their photometric or topographic characteristics—though even a cursory glance at the first photographs of the far side revealed a much greater preponderance there of mountainous areas (and a corresponding scarcity of the maria) than is the case on the side that is familiar to us

The last, and most valuable, part of the present volume consists of the reproductions of 30 frames of the individual photographs secured by the Russian space station Needless to stress, no one frame reveals all the details ascertained for that particular region from the ensemble of the material, but the best single frames appear to attain a ground resolution of some 10 miles

A map of the far side of the Moon, showing the distribution of topographic details listed in the catalogue, concludes the whole volume It is the first map of its kind, and comparable in amount of detail with maps of the visible face of the Moon available by the first half of the eighteenth century

All considered, the scientific outcome of the flight of the Russian third space station must be regarded as a splendid success, and a wonderful achievement in which the Russian nation and all their fellow inhabitants of this Earth can justly rejoice It does not mean that the days of discovery on the Moon are completely over, for a small part of its surface (approximately 40° in longitude) was not visible from the Russian space station at the time of photography and remains, therefore, still uncharted It will, however, certainly not be long before even this remaining *terra incognita* of the Earth–Moon system will reveal its secrets to the inquisitive eye of the next lunar circumnavigating device, and the pioneer days of lunar mapping will irretrievably belong to the past

The volume under review constitutes without doubt an important landmark in selenographic literature, and Pergamon Press is to be commended for the speed with which it introduced it to the English reader This speed entailed, however, also some obvious drawbacks, for by its external appearance the English edition (printed in Poland) does not come up to the quality of the Russian original, and the translation is decidedly weak—in marked contrast with the professional fluency and manner in which the preliminary report was translated, the year before, by Sykes

ZDENĚK KOPAL

IONOSPHERIC RESEARCH DURING THE INTERNATIONAL GEOPHYSICAL YEAR

Some Ionospheric Results obtained during the International Geophysical Year

Proceedings of a Symposium organized by the U R S I /A G I Committee, at Brussels, Belgium, September, 1959 Edited by W J G Beynon (U R S I Monographs) Pp xi + 401 (Amsterdam Elsevier Publishing Company , London D Van Nostrand Company, Ltd , 1960) 72*s*

DURING the International Geophysical Year a vast mass of data was accumulated by investigators of the ionosphere all over the world and some considerable time must elapse before these data have been analysed and fully interpreted The purpose of the symposium with which the present volume deals was to discuss the preliminary results derived from the data

The book contains sixty papers contributed by many of the leading ionospheric workers All papers are written in English and some of them have summaries in French They are grouped in approximately equal numbers under the headings (1) F-2 layer phenomena, (2) high-latitude studies, (3) disturbance phenomena, (4) ionospheric irregularities, (5) $N(h)$ profiles, (6) absorption, (7) drifts, and (8) noise, whistlers, rockets and satellites The first section contains papers on such topics as the equatorial anomaly in the F2-layer, the world distribution of ionization in this layer, and on the forecasting of world values of ionization density Section (2) is mainly concerned with the morphology of sporadic-E ionization and of black-out in polar regions In section (3) there are eight papers, most of them very brief, on ionospheric storm phenomena Two other papers in this section deal with the effects of the two Johnston Island nuclear explosions in the ionosphere and on radio signals traversing it The phenomena of spread-F and sporadic-E ionization are considered in section (4) where some interesting observations of both phenomena in equatorial regions are described Some of the early results of calculation of the variation of ionospheric electron density with height above Earth are given in section (5) Of particular interest in this section are contour charts, for four separate times of day, showing the variation with height of the plasma frequency along the 75° W meridian

Section (6) deals with investigations of ionospheric absorption by the pulse reflexion method and by measurement of cosmic noise Section (7) is noteworthy for three Russian papers on movements of ionospheric irregularities and for a preliminary report on the results of world-wide measurements of horizontal drifts in the F-layer The papers on atmospheric noise in section (8) include a short summary of the measurements made throughout the world , no results are given in this paper but the section includes other papers giving results obtained in both the U S S R and Japan Rockets and satellites are dealt with by American authors one paper is a very concise record of the results of ionospheric measurements by American rockets, the other paper deals with the determination of total ionospheric electron content below a satellite by Faraday rotation observations

As all these papers were written very soon after the end of the International Geophysical Year it is not surprising that many of them contain information of a very tentative character, and others are little more than brief reports on phenomena in a very early state of investigation Indeed, some of the papers have been made obsolete by later publication by the same author before the appearance of the present volume It is, nevertheless, a useful record of the symposium and is well edited and well produced It is a pity that its high price will deter many workers from adding it to their private bookshelves

A F WILKINS

PRANDTL'S COLLECTED PAPERS

Ludwig Prandtl

Gesammelte Abhandlungen zur Angewandten Mechanik, Hydro- und Aerodynamik Herausgegeben von Walter Tollmien, Hermann Schlichting und Henry Gortler, Schriftlietung F W Riegels Erster Teil Pp xix + 1–574 Zweiter Teil Pp xiii + 575–1071 Dritter Teil Pp xiv + 1071–1620 (Berlin Springer-Verlag, 1961) 273 D M , Ganzleinen 288 D M

THE monumental work of leaders of nineteenth-century physical science, such as Helmholtz, Kirchhoff, Kelvin, Maxwell, Boltzmann and Rayleigh, in creating a structure of concepts by means of which physical and engineering phenomena could be understood and predicted, was of such comprehensive character that the task of those who had to follow them and lead the way to the explanation of the mysteries that remained was formidable indeed No hope lay in continued logical building on the structure of their predecessors On the contrary, completely new intuitions were required

The scientific public knows well how these were introduced into the physics of atoms, molecules and radiation by Planck, Einstein, Rutherford, Bohr and the rest The revolution in mechanics is less well known No better grasp of it can be attained than by a study of these three admirably produced volumes containing the collected papers of the leader in that revolution, Ludwig Prandtl

The mystery in this field at the turn of the century was thickest in the mechanics of liquids and gases Three of the eight main groups of papers into which these volumes divide Prandtl's work are devoted to the three outstanding new intuitions by means of which light was to be shed on that mysterious subject

The first of these, chronologically speaking, a joint achievement of Stodola and Prandtl, was the elucidation of steady supersonic flow, stimulated at the time by the requirements of steam turbine nozzles, though later to become the foundation of supersonic aerodynamics It included a full description of the effect of varying the nozzle back-pressure, through and beyond those values which force supersonic flow to terminate at a normal shock-wave in a range of positions and strengths, to the values where a supersonic jet is produced, the structure of which was sketched by means of the ideas of oblique shock-waves and of what were later to be called Prandtl–Meyer expansions A preliminary theory of shock-wave structure was also obtained in these early years Prandtl's later work on gas dynamics, with Busemann, evolved a highly versatile and accurate theory of two-dimensional supersonic flows, using the geometry of their characteristics, and so derived jet shapes and flows about aerofoils with closer experimental agreement It is interesting to note too, in this group of papers, not only the detailed studies of the effect of compressibility in subsonic flow but also a short work of 1938 giving clear warning of supersonic bangs and considerable detail about their geometry

The famous elucidation of the true role of viscosity followed closely that of compressibility, the paper stating all the essential properties of laminar boundary layers being presented in 1904 The nature of turbulent boundary layers was appreciated soon afterwards, and a 1914 paper used the two concepts to explain the extraordinary vagaries in the drag of spheres Each of these well-known papers includes a lovely *experimentum crucis* Later investigations in the group of papers devoted to boundary layers and frictional drag relate to the law of turbulent resistance of smooth and rough pipes and plates

The third new branch of fluid dynamics created by Prandtl, perhaps the one of greatest technological importance, was the theory of lift and lift-induced drag It was a complete lifting surface theory that Prandtl, with his pupils Betz and Munk, derived and applied to monoplanes, biplanes, propellers and other systems As might be expected, the largest section of Prandtl's collected papers is devoted to all its ramifications

The volumes are a reminder, nevertheless, of the outstanding achievements of Prandtl in fields quite different from those so far mentioned A long section devoted to elasticity, plasticity and rheology reminds us of Prandtl's striking contributions (followed up by his pupil von Kármán) to a reconciliation of theory and experiment in elastic stability We recognize, too, his early appreciation of the practical significance of 'perfect plasticity' theory, which he elaborated mathematically on lines parallel to those of the supersonic flow theory to illuminate hardness tests, extrusion and the like, and which, with his work on permanent set, rupture, and materials the stress-strain relations of which include a relaxation time, helped to create the mechanics of solids as we know it to-day

Another section is devoted to vortex development and turbulence, including the rolling-up of vortex sheets, flows past sharp edges, rotating cylinders, etc In turbulence theory proper, Prandtl's momentum transfer theory attached too little significance to the role of big eddies, but the theory and associated experiments illuminated to a substantial degree the effect of temperature gradients on turbulence and, conversely, of turbulence on heat transfer, as well as a host of complex phenomena such as the secondary flow in straight pipes of non-circular section.

The meteorological section includes Prandtl's computation of the distribution of wind velocity and direction near the ground (Ekman spiral) using a turbulent exchange coefficient It includes also his contribution to the understanding of why the west-east momentum in the general circulation of the atmosphere is transported on the average at a positive rate from the tropics to the temperate zones (even though any 'random' mechanism would cause it to flow the other way, down its gradient) Prandtl noted, in this context, that any loss of energy in the high-altitude west–east circulation (due to large-scale disturbances) would reduce the Coriolis force balancing the poleward pressure gradient, and so permit poleward movement down that pressure gradient until the energy had been restored, and he noted also that the geostrophic relation between poleward pressure gradient and west–east momentum implies that energy-restoring motions must also make the west–east momentum flow polewards Other illuminations in this field include work on the structure of fronts, and, remarkably enough, an original paper dated 1950 on the dynamics of the jet stream

The volumes close with a section covering many of Prandtl's significant contributions to experimental technique, which laid the foundations of modern low-speed and high-speed wind-tunnel practice (and, as a curiosity, included experimental studies in a rotating room), followed by a group of miscellaneous papers, among which stand out a beautiful piece of work on bearing lubrication and some eloquent advocacy of the use of vector analysis

Those who love theoretical and applied mechanics can be recommended, if necessary, to curtail some future holiday in order to be able to afford these absorbingly interesting volumes Such a drastic measure might also enable them peacefully to enjoy the pleasures of their first perusal!

M James Lighthill

THEORY OF BOUNDARY LAYERS

Boundary Layer Theory

By Dr. Hermann Schlichting Fourth edition. Translated by Dr J. Kestin. (McGraw-Hill Series in Mechanical Engineering) Pp xx+647. (New York McGraw-Hill Book Company, Inc ; London McGraw-Hill Publishing Company, Ltd, 1960) 128*s*

New Methods in Laminar Boundary-Layer Theory

By Dr D Meksyn Pp xxiv+294. (London and New York Pergamon Press, 1961) 70*s* net.

THE concept of the boundary layer was discovered by Prandtl in the first years of the present century, and since then it has occupied a central position in fluid mechanics The boundary layer is essentially a skin effect, which occurs in the flow of a fluid with small viscosity, but the behaviour of the layer may have a profound influence on the general character of the whole flow For this reason, the mechanics of the boundary layer is of great importance to engineers and mathematicians interested in the problems of fluid flow. In recent years the study of boundary-layer flow has attracted increasing attention, both theoretically and experimentally, and a great number of papers have appeared on this subject

Prof Schlichting has been one of the leading contributors in this field, and his book, which was originally published in German ten years ago, has now appeared in its fourth English edition This follows the same general plan as the first German edition, but the accretion of new material has made it considerably bigger The first part provides the basic physical ideas and the fundamental equations for the flow of viscous fluids Some of the exact solutions of these equations are discussed, and there is a chapter on the approximate solutions which are valid when the viscous forces are dominant over the inertia of the fluid Laminar boundary layers are treated in the second, and longest, part of the book This side of the subject is the most fully understood, and has received extensive mathematical treatment A full account of two-dimensional flow is given, including chapters on heat transfer and compressibility Axisymmetric and three-dimensional boundary layers are treated more briefly, and there is a chapter on boundary layer control

The third part is on the transition from laminar to turbulent flow It contains a description of the theory of hydrodynamic stability, its experimental verification and its relation to the formation of turbulence The factors influencing stability are considered, with applications to the flow over aerofoils The last section of the book deals with fully developed turbulent flow Here the treatment is of necessity largely empirical, and based on the analysis of experimental results Separate chapters deal with flow in pipes, over flat plates, with the calculation of turbulent boundary layers, and with free turbulence in jets and wakes

Schlichting's book is written for engineers, and emphasis is placed on those methods and results which are likely to prove most useful Topics which are not yet amenable to routine calculation, such as the flow over a general three-dimensional surface, are dealt with only briefly Each chapter has an extensive list of references, and there are many figures illustrating theoretical results and experimental observations In a book on such a quickly growing subject there is inevitably scope for improvement and addition in detail, but it is likely to remain a standard work for several years. The legend of Fig 5 15, on page 90, has an error, and a corresponding one is made in the description, on page 91, of the effect of Reynolds number on the flow in a divergent channel. The book is well produced and clearly printed

The scope of Dr. Meksyn's book is more limited, as its title indicates It is concerned with mathematical methods, and deals mainly with steady laminar flow and with stability theory The author has written several papers on these subjects since the War, and his book presents a systematic account of his work Other aspects of laminar boundary layers are mentioned rather cursorily. The reader who is already familiar with boundary-layer theory may find Meksyn's methods of interest, but he would be well advised to check the formulæ carefully The original papers contained several errors, of which most have been corrected, but some still survive There are a number of minor slips

E J Watson

MEASUREMENT OF WATER-FLOW

Hydrometry

Theory and Practice of Hydraulic Measurements. By Prof Adam T Troskolanski Pp xix+684 (London and New York Pergamon Press, Warszawa Panstwowe Wydawnictwa Techniczne, 1960) 120*s*. net.

WHEREAS in most other countries 'hydrometry' means the science of water-flow measurement, in Britain it has been connected with measuring the density of liquids The title of this book is therefore yet another example of a distinguished foreigner teaching us our own language

Although water-flow measurement is one of the oldest sciences, it has not been well documented and we are therefore indebted to Prof Troskolanski for providing a comprehensive survey of the subject Before entering the Technical University of Wrocław, the author was chief engineer of the Polish National Bureau of Measures and therefore writes with authority, both as engineer and scientist He has confined himself mainly to water-supply engineering, although water-flow measurements for the hydro-electric industry are mentioned briefly

This new book is an enlarged version, in English, of Volume 3 of the author's text-books *Hydromechanika Techniczna* and includes new chapters on recent advances, such as magnetic flow-meters, radioisotope techniques and water-level measurements by γ-ray probes

The three main sections are (1) units, and principles of measuring length, area, volume, time, pressure, velocity, flow-rate and total flow , (2) instruments and techniques for measuring these physical quantities ; (3) laboratories for calibrating instruments and absolute standards of flow measurement

The subject is dealt with logically and in considerable detail All equations are dimensionally consistent, but in addition both British and metric units are used throughout. The author's philosophy is that measurement of the flow is a special branch of metrology, depending fundamentally on measurements of length, time, etc Such basic aspects are covered in detail in the first section, leading up to the measurement of flow-rates and total flow

It is difficult to understand why the translator preferred "intensity of flow" to the more widely used term "flow-rate" Similarly, "potential-head" is used rather narrowly It is not generally the same as the height of filling of a tank, unless the bottom of the tank is the zero potential datum However, despite such minor criticisms, the translated text is lucid and much careful revision has gone into the notation, where even the mnemonic subscripts have been translated into English British standards have been widely used and quoted

The second section gives a full account of measuring instruments and recorders, including several not usually described in English text-books, such as the Andersson travelling screen, measuring cascades, Danaïdes, and the detailed analysis of current meter performance and calibration Instruments used in water-supply practice, such as level gauges, construction and mechanical flow-meters, are particularly well described

The final section, on hydraulic laboratories and meter calibration, provides the sound foundation which is so often missing in books on measuring instruments Accurate calibration is essential, and it is valuable to have detailed descriptions and recommendations for reliable test facilities

The descriptive material is excellent and is well illustrated, together with many physical tables and a comprehensive index in English, French and German Some of the information about fields other than water supply is a little out of date For example, both the Allen and Gibson methods have now been accepted internationally for the latest International Electrotechnical Commission code for water turbine testing Sodium chloride has been largely superseded by other chemicals in the salt titration technique

The Allen salt-velocity method is reviewed more unfavourably than it deserves in view of its successful use in the United States and elsewhere On comparative flow measurement tests no more recent references than the Walchensee tests of 1926 are quoted, nor *is it made sufficiently clear that the weir is a secondary* method of flow-measurement and for highest accuracy must always be calibrated

However, in general this is a most valuable collection of detailed information, set out clearly and logically, on a subject which until now has not been well documented It can be recommended to all hydraulic engineers interested in flow measurement

S. P HUTTON

A HISTORY OF METALLOGRAPHY

A History of Metallography

The Development of Ideas on the Structure of Metals before 1890 By Prof Cyril Stanley Smith Pp xxi + 291. (Chicago University of Chicago Press, London Cambridge University Press, 1960) 8 50 dollars, 68*s*

THIS volume, which has been eagerly awaited by those aware of its preparation, was worth waiting for In the author's own words, "Perhaps the study even has a certain timeliness, for it is abundantly clear that the proper balance between 'applied' and 'pure' science that is necessary for technological and cultural well-being has yet to be achieved"

Broadly the book is divided into three main sections, first the background of metallography in ancient works of art, then the philosophical background and the observations of structure before the use of the microscope, and finally, the period of increasingly active observation and theory from the time of Sorby onwards It is a story that involves the history of art, of 'natural philosophy' and of technology, and ends about 1890, by which date metallography had begun to be recognized as a definite discipline in its own right, though Chapter 16 does carry the story down to recent years Two appendixes give in full a paper of Sven Rinman of 1774 on "Experiments of Etching upon Iron and Steel", and Sorby's paper of 1885 to the Iron and Steel Institute "On the Microscopical Structure of Iron and Steel" which differs considerably from the version published in 1887 and of which few are probably aware A long list of bibliographical notes bears testimony to the extent of the sea over which the author has cast his net, the catch being a work of real scholarship as well as a first-rate contribution to the history both of science in general and of metallurgical technology in particular

The earlier portion of the book dealing with the relation between æsthetic appearance and structure is concerned with the fact that, long before it was appreciated by the philosopher that metals are aggregates of innumerable small crystals randomly packed together, this existence of 'structure' was used by the artisan to produce his effects "Differential chemical attack was used in Europe to give a decorative mark of quality to swords as early as the second century A D , but the technique passed out of use" though in the East surface texture did continue in use for this end "The superiority of the swords of Damascus and Japan stemmed directly from the fact that the smith related a certain visible texture to the serviceability of the weapon and adjusted his manufacturing process to produce it " That metal workers have been on occasion intuitively sensitive to the inner structure of their materials and have empirically developed ways of revealing it there can be no doubt, and such observations clearly led to the deliberate choice of manufacturing methods as well as of a kind of metallographic control over the working and heat-treatment processes required in order to obtain the surface structure desired both for beauty and service

The section which describes the gradual development of the idea of a metal as an aggregate of crystals is the most substantial and, in many ways, the most interesting of the whole book The anti-Aristotelian trend of the early seventeenth century paved the way for renewed consideration of the inner nature of metals, and Descartes himself must have been a close observer of the operations of the iron-smelters and of the smith In 1639 he was in correspondence with Mersenne regarding the reason for the hardening of steel, and it is quite clear that he had watched the production of wrought-iron during its manufacture in the finery hearth "The whole bath of molten metal becomes divided into many small lumps or drops, the surfaces of which become smooth" Although these early ideas were necessarily crude, often inaccurate, and, from a modern point of view, often bordering on the fantastic, Rohault, in 1671, in his *Traité de physique*, when discussing the properties of ductility and hardness, could say "we cannot but think that the component Parts of Metals are long, otherwise we cannot understand how Metals should be so ductile as they are, whether they be forged upon an Anvil or drawn through a wire-drawing Iron, whereas if we suppose them to be somewhat long, it is easy to conceive, that when they are pressed on one Side, they slip sideways of each other without quite separating Further—we cannot but think that they must necessarily so order themselves as to place themselves by each other's Side, and correspond Length-ways to the Length of the whole Piece, which will make it easier to bend that Way than any other—And we find Strings in them, as in the Slip of an Ozier These Strings ought not to be in a Metal that is cast and has not been forged And so we find that cast Metal is as easy to break one Way as another" It was, however, left to de Réaumur to develop such corpuscular theories into something useful, and a century before the 'particles' of such theories had developed into the chemical atom on one hand, and the stacking of polyhedra had given rise to mathematical crystallography on the other, Réaumur was using the idea of 'parts' aggregated together on different scales to develop theories regarding the nature of iron and steel and to explain the structures which he saw on fractured metals

The final section, essentially the work of Sorby and his successors, brings the story down to men known personally to the older generations still alive Sorby himself, Arnold, Stead, Sauveur and evidently to the author Martens and Osmond in particular all play their parts The bitter controversy which raged regarding the relative importance of carbon or a hard allotrope of iron is recalled, and it is perhaps not without a feeling of justice to those on both sides to remember that, to the best of our present-day knowledge, the true explanation contains an element of both theories As McCance was probably the first to suggest explicitly, a highly distorted iron lattice the distortion being due not to allotropy but to the high state of supersaturation of carbon in the quenched steel, is as near as the ordinary metallographer probably needs to go

Beautifully produced and illustrated, this is a book which both Prof Smith and the publishers will look on with real pride F C THOMPSON

THE MECHANICS OF VIBRATION

The Mechanics of Vibration

By Prof R E D Bishop and Prof D C Johnson Pp xii+592 (Cambridge At the University Press, 1960) 120*s* net

THIS is a book written with painstaking care on the subject of the basic principles of mechanical vibration and their application to the study of specific problems Its title and contents direct attention to the diversity of meanings that may be attached to the word "mechanics" To some engineers this book, being largely algebraic, will appear to be abstrusely mathematical, to a mathematician the mathematical operations in it are elementary The engineer may be appalled by the authors' insistence (on p 96) that they are restricting their attention to the mechanics of vibration and that the mathematics is a separate subject that they hope to present in another volume He may clutch at a straw floating on p 114 because it suggests that the mathematical part of at least one problem may be "reduced to arithmetic" The quantity of arithmetic involved in some solutions, however, implies a generous interpretation of the word 'reduced'

A good deal of space is rightly used in demonstrating applications of the concept called 'receptance' in 1954 after earlier use of the name 'mechanical admittance' for it by Prof W J Duncan in *Reports and Memoranda* No 2000 (1947) of the Aeronautical Research Committee, mentioned in several places in this book It may be added that the application of this concept to mechanical problems is much older than either of these names for it

A chapter on "The Analysis of Real Systems" begins with a quotation from Routh and refers to Rayleigh's principle, Dunkerley's method and Southwell's theorem in a succession that directs attention to nice distinctions in nouns

It is remarkable to find, in this book, a suggestion that for the purpose of calculating its natural frequencies, a system of rotors and shafts in series may be replaced by one composed of distributed masses, merely to avoid the Holzer tabulation which is laborious for a system of more than 3 or 4 masses The Holzer procedure is in fact a good way of calculating relative amplitudes of vibration for a known natural frequency, but as a means of determining frequencies it is at least thirty years out of date and ought never to be used for that purpose either with or without electronic 'brains' The rational procedure is a routine well within slide-rule range

In Chapter 7, reference is made to the method of estimating the lowest natural frequency of flexural vibration of a small non-uniform beam and the calculated value is compared with that determined by actual trial The smallness of the discrepancy inspires confidence in the mathematical procedure but without weakening the impression that where instruments for exciting and measuring vibration are available, testing of a model is a quicker and more reliable alternative to calculation as a means of determining natural frequencies of certain types of systems

The chapters on damping of vibration show that even when the usual drastic assumptions are made about the quantitative characteristics of damping, it is a seriously complicating circumstance in analysing any but the simplest vibrating systems Abandonment of those assumptions leaves difficulties that cause the authors to remark that "The assessment of damping is a subject in which research is needed" This describes with great delicacy the present state of knowledge of this particular subject

In the last chapter the authors introduce the subjects of "Non-harmonic Vibration and Transient Vibration" and show them to present much more formidable analytical problems than any solved by the authors or others in the subject of harmonic vibration Reflexion on this helps one to understand why some practical problems in vibration are analytically refractory and perhaps analytically insoluble

Any mechanical science graduate who studies this book and works through its numerous and excellent examples ensures for himself a thorough grounding in the theory of mechanical vibrations

W A Tuplin

INDUCTANCE COILS

The Theory and Design of Inductance Coils

By Dr V G Welsby Second edition Pp 232 (London Macdonald and Co (Publishers), Ltd , 1960) 30*s* net

DR WELSBY'S book on the design of inductance coils, first published in 1950, has now reappeared as a revised second edition Those who are familiar with the first edition will know that the book contains very extensive formulæ for the calculation not only of the inductance of coils but also of the effective resistance and the effective shunt capacitance The coils considered are air cored with solid and stranded wire, and those with laminated ferro-magnetic cores, with dust cores, and with ferrite cores The theoretical treatment given is not always as detailed as in the original papers but references are given for those who wish to study the theory fully, while the theory and formulæ given in the book are fully adequate for all whose main concern is to design and make efficient coils

The author is careful to explain the limitations of theoretical formulæ for coils with magnetic cores, but a slight amplification of the parts of the book covering experimental results and methods of correlating theoretical formulæ with these results would add to the practical value of the book

The two principal changes in the present edition are the use of M K S units and the use of the principles of electromagnetic wave propagation to derive some of the formulæ Both changes represent an improvement, but in both cases the new material is not entirely happily welded into the old It is difficult to justify the author's use of the symbol η in place of μ_0 for the magnetic constant of space, the use of μ in place of μ_r for relative permeability, and the use of μ_0 for initial permeability, except on the basis of preserving inviolate some of the formulæ given in the first edition The factor 10^{-9} is also to be seen in many of the formulæ instead of the factor 10^{-7} more usually associated with M K S formulæ

The theoretical treatment tends to be most detailed for the simpler parts and to be uncomfortably condensed for the difficult parts In particular, clearer and more detailed explanations of the method of applying field theory to the solution of coil problems would be advantageous It is rather surprising also, in view of the author's liking for field theory, that capacitance is treated as if it were in shunt across the coil terminals and not as a distributed effect

These minor defects should not be allowed to obscure the real value of the book, covering in the space of 230 small pages a great quantity of most useful information not readily found elsewhere

A H M Arnold

DIFFUSION AND HEAT FLOW IN LIQUIDS

Diffusion and Heat Flow in Liquids

By H J V Tyrrell Pp xii+329 (London Butterworth and Co (Publishers), Ltd , 1961) 65*s*

THOUGH somewhat uneven in its treatment of various themes, this book is a valuable and scholarly addition to texts dealing with certain irreversible phenomena in liquids Chapters on the principles of non-equilibrium thermodynamics, on concentration diffusion, and on thermal diffusion are informative and well balanced Descriptions of experimental methods for investigating various kinds of diffusion processes cover present practice in a very useful way, by comparison, a chapter on thermal conductivity measurements seems much less extensive Interpretation of the phenomena observed is presented in the form of discussions This part of the book will probably need revision soonest, since experimental information in the fields examined is growing rapidly

One chief difficulty in discussing the interpretation of transport processes in liquids stems from their correlation with viscosity At present, there seems to be no widely applicable treatment for linking viscosity with diffusion, despite the great convenience of viscosity coefficients for describing certain types of relaxation in liquids For liquids of very simple structure, viscosity coefficients for relaxation of simple macroscopic shear have been related theoretically with mass migration, for example in the theories of Eyring However, Eyring's models do not deal with the variety of specialized micro-relaxation processes which can occur in liquids containing polyatomic molecules, and in ionic solutions and melts Viscosity coefficients tend to be injected quite generally into interpretations of transport processes without adequate recognition or description of their limitations This book does not avoid the difficulty The author's discussion of liquid viscosities is very incomplete This unavoidably restricts the assessment of various molecular models devised to represent transport processes in liquids, in terms of their structure

Despite this gap in the discussion of transport processes in liquids, the present book can be commended to research workers and libraries, particularly those concerned with diffusion phenomena Scientific interest in diffusion is widening The author's discussions of work on the separation of components by thermal diffusion should help to promote technical advances in this field

RADIOACTIVE WASTE DISPOSAL

Atomic Energy Waste

Its Nature, Use and Disposal Edited by E Glueckauf Pp xi + 420 + 4 plates (New York Interscience Publishers, Inc ; London Butterworth and Co (Publishers), Ltd , 1961) 95s

THE days are long past when industrial wastes could be discharged uncontrolled to the environment, and the new atomic energy industry has developed in a period which has seen new legislation introduced generally for the control of environmental pollution and specifically for radioactive discharges Strict legislation (described in one of the articles in the book), a very sensitive public awareness and an exceptional concern with health hazards within the industry have stimulated a considerable amount of research on radioactive wastes

A considerable part of the research is reviewed in this book It is concerned primarily with the fission products separated as waste in the processing of nuclear fuels, which are regarded as the source of ionizing radiations to be used for man's benefit. It develops in more detail, and indeed in considerable detail, some of the views presented by the editor in a paper to the Second International Conference on the Peaceful Uses of Atomic Energy, wherein the fission products were seen as a source of radiations, of rare and precious elements and of specific radionuclides available for peaceful uses of atomic energy

The book concentrates on the utilization of the liquid fission product waste as a source of ionizing radiations It is not a general text on radioactive waste disposal The small-scale use of radionuclides and the wastes arising are deliberately excluded , there is no account of the wastes arising at nuclear power stations , and although one good chapter is devoted to dispersion of activity from chimney stacks, there is no account of the treatment of solid and gaseous radioactive wastes

The book consists of seventeen separate articles The first, nearly a quarter of the book, describes the fission process and the fission products, nearly half of it in tabular and graphical form This article and one on radiation chemistry, though good in themselves, go into far more detail than is required for the discussion of radioactive waste disposal By contrast, the articles on α-emitters in reactor wastes, effects of radiation on living cells, movement of radioactive substances in food chains and radiation protection present the broad aspects and concentrate on the essentials

While the first half of the book, the introductory or background part, is somewhat uneven in its treatment of the topics covered, the second half contains good review articles of the processes and operations used in the treatment of liquid radioactive wastes, the design of irradiation units using packaged sources and the uses of ionizing radiations for agricultural research, food preservation and induction of chemical reactions

The treatment, perhaps naturally, leans towards British practices Space might have been found for a more detailed discussion of wastes from fuel processing in other countries and of wastes from the processing of fuel elements made from stainless steels and zirconium alloys The work carried out in the United States on disposal in salt formations and by deep-well injection might also have been described The therapeutic use of ionizing radiations is a less easily understood omission Some comparison of radiations from nuclides and radiations from machines, particularly in food preservation, would have been valuable

Only a few errors were noted The last entry on p 251, referring to the allowed discharge from the Atomic Energy Research Establishment, Harwell, should be 20, not "2" On p 227, what is referred to as slow sand-filtration, a method of treatment of drinking water, is really the trickling filter process for sewage purification In the glossary, the 'rad', a unit of absorbed dose, is defined as a unit of amount of radiation

The book is authoritatively and well written and well produced It should, as the editor intends, illuminate "the background from which future developments can emerge" A W KENNY

AN AMERICAN TAPESTRY OF STATISTICS

Contributions to Probability and Statistics

Essays in Honor of Harold Hotelling Edited by Ingram Olkin, S G Ghurye, Wassily Hoeffding, William G Madow and Henry B Mann. (Stanford Studies in Mathematics and Statistics, No 2) Pp x + 517. (Stanford, Calif Stanford University Press, London Oxford University Press, 1960) 52s. net

THE name of Prof Harold Hotelling is chiefly familiar to English students of statistics as one of the founding fathers of that branch of their subject known as multivariate analysis His share in the foundations was laid in half a dozen outstanding papers of the early 1930's, and the bibliography given here shows that this period saw his major contribution to theoretical statistics and that later he has been more concerned with applications, chiefly to economics It might seem strange, on the face of it, therefore, to find a volume of 38 papers offered to him on his sixty-fifth birthday by statisticians for the most part very much of the mathematical variety But Prof Jerzy Neyman's introductory article shows clearly that Hotelling has been a powerful formative influence in American statistics and provided it with much of the dynamic which got it really under way Not only did his papers help, at a crucial time, to demonstrate to the American mathematical and statistical worlds that statistics could be, simultaneously, both scientifically useful and mathematically rigorous but, over and above this, he seems also to have had a talent, akin to genius, for picking students and staff of outstanding ability and firing their enthusiasm for statistics The list of thirty such men (some no longer living) which Neyman gives is extremely impressive and of these about a score contribute to the *Festschrift*

The papers included are all on topical problems of theoretical statistics, and it is not untoward that only a minority refer to Hotelling's own work, since, as has been said, his major theoretical contributions are now embodied in the corpus of statistical classics There is no unifying theme here The topic treated by any given author could have been predicted from his own previous publications with some accuracy The only obvious difference between this collection and, say, the last volume of the *J Roy Stat. Soc* (B) is that the papers here are slightly shorter on average This reflects the fact that though the papers here tend to be more fluent and essay-like than a typical journal article, they are, by and large, slighter As a consequence, they are for the most part easy to read But it would be a hopeless task to attempt to review all of them, or even to try to pick out objectively the most important All I can do is to mention some that caught my fancy These include the two offerings from England, by M G Kendall and M S Bartlett, the latter discussing his concept of quasi-stationarity which promises to be, in one form or another, a key idea in the future development of stochastic process theory Bradley and Prendergast extend modern ranking theory which already owes much to the former author Block and Marshak have an intriguing paper on a cognate topic. Roy and Bhapkar expound and develop the Pearson–Roy logical analysis of multiway contingency tables. But perhaps the tributes which do Prof Hotelling most honour are the papers by Bowker and Wilks developing classical multivariate analysis, and that of Stein, who looks at it from the most recent Californian point of view D E. BARTON

ANALYSIS ON RIEMANN SURFACES

Riemann Surfaces

By Prof Lars V. Ahlfors and Prof Leo Sario (Princeton Mathematical Series, Vol. 26) Pp x+382 (Princeton, N J. Princeton University Press, London· Oxford University Press, 1960) 80*s*. net

THE modern era of Riemann surfaces was ushered in by H Weyl's book *Die Idee der Riemannschen Fläche* Here we find for the first time the systematic development of the idea of an abstract Riemann surface as an analytic manifold of one complex dimension, essentially a space with local parameters related in such a way that two distinct parameters are regular functions of each other in their common region of definition. Since the Second World War there has been a tremendous development in the field and books have appeared by Nevanlinna, Pfluger, Schiffer and Spencer, and Springer, for example

Ahlfors and Sario's *Riemann Surfaces* goes further than its predecessors The first chapter contains all the necessary topology which plays a fundamental part in the theory The next chapter introduces Riemann surfaces and some of the basic methods for treating them, subharmonic functions, and the problem and integral of Dirichlet, Rado's theorem about the separability of Riemann surfaces which follows in a particularly simple and elegant way, and the fact that a smooth Riemannian metric on a surface induces an essentially unique conformal structure, a result which is frequently stated but seldom proved The third chapter treats functions with singularities on a surface by Sario's elegant method of normal operators and deduces the principal mapping theorems for planar surfaces, that is, those topologically equivalent to plane domains Such surfaces can be mapped on a plane domain bounded by various kinds of slits In the simply connected case, we obtain the closed or open plane or the unit disk

The second half of the book consisting of the last two chapters is more for experts. The fourth chapter introduces a complete exposé of the modern theory of degenerate surfaces, that is, those not admitting functions of various kinds and their inter-relations. This subject was opened by Ahlfors in the late 'forties and the solutions of the problems raised by him have now been almost completely obtained by the authors of the present book and others The last chapter treats differentials on arbitrary Riemann surfaces and finishes with a welcome section on the classical theory of integrals on closed surfaces and the Riemann–Roch theorem

This is an authoritative and long-awaited treatise by two of the greatest experts in the field The elegant formulation of many of the ideas and proofs have made it possible to include more material than there is in any other book on the subject The presentation is fairly clear but the subject is difficult, and particularly in the latter chapters the approach is very abstract If one wishes to have complete generality and at the same time prove the classical theorems, it is most economical in time and space to deduce the latter from the former, but it is not necessarily the easiest way for the reader Although this book is completely self-contained, I should recommend it rather to those readers who already know something of the subject—having looked, for example, at G. Springer's *Introduction to Riemann Surfaces*—than to the complete tyro. As a reference book, however, and a complete survey of all techniques right up to the frontiers of the subject, it is unequalled, and every serious mathematical library should contain it W K HAYMAN

MODERN GEOMETRY

Lectures on Modern Geometry

By Beniamino Segre (Consiglio Nazionale delle Ricerche—Monografie Matematiche, 7) Pp xv+479 (Roma Edizioni Cremonese, 1961) 7,000 lire

MODERN geometry is a term which has seen service in many campaigns and under many commanders However, in the present instance, the use of the title is not only justified at the moment but also stands a good chance of remaining so for some time to come, for this book, which is a greatly enlarged version of an Italian original of 1948, completes in various respects a generalization which has been under way for centuries

Algebraic geometry as we know it to-day stems from two main sources the invention of co-ordinates, and the analysis of axiomatic structure The latter process has given a whole series of shocks to intuition; these, once absorbed, have led to the creation of new geometries which find their natural expression in terms of suitable co-ordinate systems. In a definitive account this process may well be reversed; in Prof Segre's work we have examples of both procedures.

Part I of the book is a lucid exposition of the algebraic concepts and results which are required later A useful innovation here is the term corpus to denote a general field, the latter name being reserved for commutative corpora. Part 2 is devoted to the foundations of projective geometry over an arbitrary corpus. The first chapter deals with linear spaces, that is, geometry based on homogeneous point co-ordinates In the second chapter, which is concerned with graphic spaces, the approach is axiomatic a graphic space is any set of abstract elements ('points') which satisfy the incidence relations of projective geometry On this basis one proceeds to erect a co-ordinate system

At this point Desargues' theorem on triangles in perspective comes into play. It can be shown that the theorem holds in every linear space, but that there are graphic planes in which it is false. In contrast with the situation in higher space, Desargues' theorem in the plane is not a consequence of the axioms of projective geometry A second group of results concerns Pappus' theorem (that is, Pascal's theorem for a line-pair) it may be proved that this theorem holds in a plane if and only if the corpus defining the co-ordinate system is commutative Also the theorem cannot be established on the sole basis of the incidence postulates and Desargues' theorem, but Desargues' theorem can be deduced from these postulates together with Pappus' theorem

There follows a very interesting chapter on finite linear spaces, a subject to which the author has made fundamental contributions during the past few years It is here, in the geometry of a finite number of points, that intuition receives its gravest shocks and that seemingly unshakeable theorems tumble like ninepins

A substantial appendix by L Lombardo-Radice on non-Desarguesian finite graphic planes takes the theory further, but much has happened in the two years since the book went to press The style and content of this work are such as we have come to expect of the distinguished author, whom all geometers will thank for this valuable addition to the literature

L ROTH

"OPINIONS OF THE LATE AND BEST PHISITIANS"

Tobacco

Experimental and Clinical Studies—a Comprehensive Account of the World Literature By Prof P S Larson, Prof H B Haag and Prof H Silvette Pp xii + 932 (Baltimore, Md The Williams and Wilkins Company, London Baillière, Tindall and Cox, Ltd , 1961) 160*s*

IN 1595, an anti-smoking tract appeared in England entitled "Opinions of the Late and Best Phisitians concerning Tobacco", establishing a tradition of criticism which has persisted to the present day This reference does not appear in the book under review, but there can be few of scientific interest which are not included The authors' stated intention is "to be deliberately non-selective, printing good work and bad, sound and uninformed opinion, alike, in the same type", for they discovered that "there was scarcely to be found consistency of data in any area of observation, and unanimity of interpretation was even more rare" The result is an enormous work with more than 6,000 references It is not, however, an unevaluated mass of contrapuntal observations, echoing the disagreements of a century and a half, for the authors have decided views expressed by length of quotation, inclusion of critical reviews, and their own comments on methods and principles of research

The authors are pharmacologists, and the first part is devoted to the pharmacology of tobacco in many species

The human race has experimented on itself with tobacco so persistently that short-term effects due to nicotine must be relatively unimportant It has been said that nicotine can be regarded as a naturally occurring hormone in regular smokers It is not significant that it can be toxic in large doses, so, after all, is adrenaline Since nicotine is the major constituent it has pride of place, and our ignorance of the other 150 constituents of tobacco smoke, 10 of which are carcinogenic, is startlingly apparent In such chronic habits as smoking these 'tracer' substances must be as worthy of study as nicotine

A large part of the volume is clinical One feels that in referring to particular diseases the aid of specialist clinicians might have been an advantage For example, the statement is made, correctly, that most authorities forbid smoking in thromboangiitis obliterans, but the patients observed by these authorities were almost certainly arteriosclerotic, and their conclusions will not stand up to critical appraisal

This is a minor criticism The authors' general critical approach could be imitated with benefit by many clinicians who are in the chase after chronic influences on chronic diseases

In most cases one must agree with the authors that the correct verdict on tobacco is "Remanded for further evidence" The greater part of the literature is critical of tobacco, but in this instance quantity does not count There is no disease from piles to coronary thrombosis for which it has not been blamed, but it has also been used to treat most of them It would be a mistake to condemn it from puritanical tendencies, when there may be beneficial effects as difficult to demonstrate convincingly as its alleged disadvantages One supposes that the habit is of some value to those who use it

KENNETH BLOOR

ÆTIOLOGY OF ALCOHOLISM: CONTROLLED OBSERVATIONS

Origins of Alcoholism

By William McCord and Joan McCord, with Jon Gudeman (Stanford Studies in Sociology, 1) Pp xi + 193 (London Tavistock Publications (1959), Ltd , 1960) 35*s* net

THIS is an important work It is a well-controlled study of a large group, of both 'normal' and 'pre-delinquent' boys, of which the original purpose was to consider the value in prophylaxis of criminality of guidance by trained social workers A vast amount of information was obtained In due course the boys grew up, and some of them became alcoholics Thus for the first time we have unprejudiced information about the alcoholic, obtained before the onset of the disease In other very numerous investigations the information necessary for evaluating pathogenesis has been elicited retrospectively and liable to many sorts of bias In the work presented in this book, bias seems to have been eliminated—partly by the multiplicity of observers and observations, partly by the absence of any design, in the original scheme, of studying alcoholism, and partly by careful coding and rating techniques

They find no support for some widely held views for example, glandular diseases, malnutrition, oral tendencies, latent homosexuality, do not correlate with alcoholism They list seventeen variables in the childhood background that did correlate with alcoholism Six were highly important (1) maternal alternation between affectionate and rejecting attitudes, (2) maternal deviance, for example, alcoholism, promiscuity, (3) paternal antagonism, (4) paternal escapism, (5) an 'outsider' in conflict with parental values, (6) absence of high demands on the child by the parents

They believe that their results indicate that by such forces the alcoholic has had developed strong desires to be dependent, but these are incompatible with the self-image in the stereotype of the American male—independent, courageous, dependable and resolute Drinking satisfies this by being a 'manly' pursuit, which yet satisfied dependency desires (I found this less cogently argued than the rest of the book)

They note differences between the personality of the pre-alcoholic and that of the developed alcoholic, and between factors that precede criminality in one, and alcoholism in another

It would perhaps be dangerous to generalize from this investigation about the genesis of alcoholism generally—there are some apparent differences between the alcoholics that the McCords describe and those with whom I am familiar Nevertheless it gives what appears to be valid and reliable information on an area in which hitherto we have had little but speculation W McAdam

THE BRITISH NATIONAL HEALTH SERVICE

The Genesis of the British National Health Service

By John Jewkes and Sylvia Jewkes Pp xi+67 (Oxford Basil Blackwell, 1961) 6*s* 6*d* net

The human and financial implications of Britain's National Health Service are so tremendous that the significance of a survey by Prof and Mrs Jewkes cannot be overrated They question the assumptions on which the National Health Service was established, challenge the validity of comparisons between Britain's centrally directed system and those of countries where the health services owe less to central direction and more to local enterprise, and have considerable reservations about whether or not the Health Service is as effective as its protagonists would proclaim

In their essay, the authors make a critical examination of the belief that, before the War, the British medical system was seriously defective and that nothing short of a centrally controlled free system could provide appropriate remedies, further inquiries are to be made into the economic and social consequences of the National Health Service As a basis for their inquiry, the Jewkes's have investigated the numbers and distribution patterns of doctors, dentists and nurses, the numbers of general practitioners in relation to the number of consultants, comparative mortality statistics and the way in which a health service might have developed if there had been no nationalized direction and control

Their findings are disturbing Although the statistics are not always revealing, it would appear that, even if the number of doctors has continued to increase under the National Health Service, the rate of increase has been no greater than that which obtained during 1921–39 The same can be said of nurses and dentists, and although, apart from our lesser number of dentists, British medical services compared favourably with those of the United States in 1939, the average American to-day is much better served, the gap between us continues to widen

With the introduction of the National Health Service it was hoped that the distribution of doctors throughout Britain would become more even Between 1911 and 1951 the geographical pattern remained largely unchanged and, although there was a slight gain in the number of doctors in more unpopular areas during 1951–59, the ratio still varies widely between north and south, spas and areas of heavy industry Specialist services have improved under the National Health Service, treatment by medical consultants being now much more widely available Nevertheless, the percentage of consultants to be found in the more attractive southern parts of the country has varied little between 1938 and 1957 Prof and Mrs Jewkes also indicate that the increase in the number of consultants owes much to the up-grading of men who, before the introduction of the National Health Service, were called general practitioners and whose titles alone have changed

A frequent complaint before the Second World War was that too many doctors carried too many patients on their panels Some improvements have taken place, but, since 1954, the position has deteriorated Between 1952 and 1959, for example, the average number of patients per principal in under-doctored areas fell only from 2,851 to 2,745 The charge, too, that older people have received far less medical attention since the introduction of the Service is also refuted by the figures

Two other points emerge from the survey. One is that, since the inception of the National Health Service, mortality-rates in England and Wales have not fallen more rapidly than in other Western countries The second is concerned with the administrative pattern of medical services and suggests that "the more sweeping criticisms of the pre-war organization of British medical services are not to be trusted and that the view that the pre-war weaknesses could summarily be swept away by a centralized organization was over-sanguine"

The findings of this inquiry raise so many issues of national importance that many people will wish to see the promised surveys into the social and economic consequences of the National Health Service Others will see that this inquiry is important not only for its own sake but also as an exercise in social science In many parts of this essay, Prof and Mrs Jewkes take exception to statements made by Prof R M Titmuss and others which were adduced to support the principle of a centrally organized health service In so doing they themselves, however unintentionally, have raised the question of whether social scientists should begin with a view and look for information to support it, or whether more profitable discussion might ensue if the inductive method of physical science were applied more faithfully Is this one of the reasons why so much of social science is still looking for its basic concepts ? T H Hawkins

A NEW MEDICAL DICTIONARY

The British Medical Dictionary

Edited by Sir Arthur Salusbury MacNalty Pp xix+1680 (London and New York The Caxton Publishing Co , Ltd , 1961) 210*s*

The appearance of this truly monumental work will be received with delight by everyone who has, systematically or occasionally, the need to consult medical journals Coinage of new words and changed meanings for old ones have led to the emergence of an English medical vocabulary which has become almost the equivalent of a foreign language to many old and new members of the profession Now, following the devoted efforts of Sir Arthur MacNalty and a team of colleagues over more than a decade, here is the very book for which we have been waiting

The production is of the highest quality, an important feature in a work which is bound to receive rough treatment The binding is stout and arranged so that, when an entry is found, the pages do not curl back in that maddening way so typical of bigger books (This one weighs 7½ lb) The paper will stand up to thumbing and the layout and type make reading easy

The quality of the 110,000 entries is in keeping with the standard of the appearance Definitions are so clear and precise that room has been found to include many variations on a single theme The term 'abscess', for example, is plainly described as a "collection of pus circumscribed in a cavity produced by tissue disintegration and displacement" The general entry, however, is followed by succinct explanations of more than 200 different kinds of abscess ranging from "atheromatous abscess" "bicameral abscess" and "collar-stud abscess" to "shirt-stud abscess" and "wandering abscess"

Each main entry is followed by its pronunciation, meaning and derivation, although readers are left to find out for themselves the pronunciation of secondary entries Where there is doubt, the simplest form of spelling is used, 'hæmospermia', for example, being preferred to 'hæmatospermia' for the condition in which "blood is discharged in the semen" Where shortening might lead to confusion, each spelling is included 'Hæmoblast', for example, is also listed as 'hæmatoblast' and 'hæmocytoblast', the actual definition appearing under the last-mentioned entry

For those who like to know at least a little about men and women whose names have left their mark on medicine, the treatment of eponyms is satisfying Baron von Munchhausen's connexion with his syndrome owes much to Richard Asher's historical knowledge and makes not only Munchhausen but also the entry 'come alive' The note about Dimitri Ivanovich Mendeléeff and, then, his Periodic Law, makes light work of mendelevium, a new transuranic element announced by Seaborg in 1955 The latter, incidentally, shows how recently some of the words in this dictionary have been coined and how wide-ranging has been the search for them

To complete this word-picture, words are included if they have any significance in medicine at all Thus, 'circuminsular' and 'circumvolute' are defined with precision along with more obvious medical words like 'circumocular' and 'circumoral' The only deliberate omissions are words which are obsolete or valueless, even here eponymous terms are included if they are still occasionally used in medical literature or have some historical interest Finally, to ensure that nothing is omitted or causes obscurity, three useful appendixes provide a firm base with a list of anatomical nomenclature, a number of physicochemical tables and specialized words used by pharmacists. The total result is a book of some 1,700 well-packed pages which will be kept up to date by cumulative annual supplements

English-speaking readers who have close or remote connexion with medicine will wish to thank the publishers for their vision and courage in producing such a magnificent dictionary They should see to it that all the editors of medical journals in countries in Europe and Asia who have been struggling to present articles in the English language should be informed of what could be a great aid to them These, and all English-speaking readers, have cause to be grateful to the editor and his distinguished colleagues for labouring so long to produce such a distinguished work Lexicographers, as Dr Johnson knew, are held high in national esteem With all his outstanding contributions to medicine, Sir Arthur MacNalty may have little thought that he is now most likely to be remembered as the editor of *The British Medical Dictionary.* K M HAWKINS

APPLICATIONS OF SCIENCE TO PEACEFUL USES

Current Trends in Scientific Research

Survey of the Main Trends of Enquiry in the Field of the Natural Sciences, the Dissemination of Scientific Knowledge and the Application of such Knowledge for Peaceful Ends By Pierre Auger Pp 245. (New York United Nations, Paris Unesco, London· H.M S.O , 1961) 33*s*

PROF AUGER'S ambitious survey of the main trends of inquiry in the natural sciences and the dissemination and application for peaceful ends of such knowledge, and on the steps which the United Nations, its specialized Agencies and the International Atomic Energy Agency could take to encourage the concentration of such efforts on the most urgent problems having regard to the needs of the various countries was undertaken at the request of the General Assembly of the United Nations This survey was carried out with the assistance of a special advisory committee and on the basis of texts prepared and supplied by the several agencies and other bodies Nevertheless, the task remains formidable and indeed forbidding, for the selection or omission of particular features must remain a matter of personal judgment which is liable to challenge, and if it is not easy to discern the precise purpose which the survey will serve, Prof Auger is to be congratulated on the courage and judgment with which he has discharged his mandate rather than criticized for particular omissions

The survey is in three parts The first, which occupies some 180 out of the total 229 pages, surveys the trends of scientific research, by functional divisions rather than academic disciplines, and is preceded by an excellent introduction on the development of research and the transition from discovery to application Here, and also in some of the separate sections, as in those on mathematics, the physical sciences, the chemical sciences and the biological sciences, Prof Auger attempts to set forth his conclusions as to the main trends in research, but in the applied sciences this is less frequently done and more open to criticism In the second part of the report Prof. Auger reviews very briefly the main factors which affect the organization of scientific research and the dissemination of its results, while in the third are set forth the recommendations concerning the practical steps which might be taken by the United Nations and the Agencies to concentrate effort on the most urgent problems from a general point of view By and large these two parts may well prove the most useful feature of the survey, the second part in particular should stimulate useful discussions, though here the absence of references is something of a drawback R BRIGHTMAN

SHORT REVIEWS

A Bibliography of the Honourable Robert Boyle, Fellow of the Royal Society

By Prof. John F Fulton. Second edition. Pp xxvi + 217 (Oxford Clarendon Press, London· Oxford University Press, 1961) 50*s* net

THE late Prof John Fulton's *Bibliography of the Honourable Robert Boyle* has now appeared in a second edition, almost thirty years after the first edition was published in the *Proceedings of the Oxford Bibliographical Society* Addenda to the first edition were also published by this Society in 1933 and 1947. In its revised form this exhaustive bibliography, with its scholarly annotations, has now been issued in one volume by the Clarendon Press, Oxford To this volume Prof Fulton has contributed a new preface, in which attention has been directed to changes rendered necessary as the result of newly acquired information. The preface to the first edition has been reprinted with "some omissions, several corrections, and a few added notes" This preface also contains some interesting notes on the dispersal of Boyle's library Major changes are few. The discovery by Miss M E Rowbottom (Wellcome Historical Medical Museum) in 1950 of a new and, incidentally, the earliest published writing of Boyle has necessitated an addition to the list of his works, and references to the large number of papers and monographs dealing with various aspects of Boyle's life and work that have appeared since the first edition have also been added It is a great convenience to have all this information incorporated in a single volume, and historians of science, librarians, bibliographers, book collectors and antiquarian booksellers will all be permanently indebted to Prof. Fulton for his work

V A EYLES

The Annual of the British School at Athens

No 55, 1960 Pp x + 238 + 59 plates (London British School at Athens, 1961) 63*s* net.

THIS volume from the British School at Athens includes a variety of interesting material It begins with a report on the rest of the pottery found at Karphi during 1937–39 with some observations on the relationship between the designs which appear on the painted wares and the patterns used for textiles Then there is Part 1 of a survey of prehistoric Laconia from the Neolithic period into the Bronze Age and even, in some cases, continuing on to Hellenistic and Roman times This is a little-known area, the scene of many incidents in the Homeric poems and other writings, and few excavations have taken place there It is followed by a consideration of Minoan trade relations as reflected by the Minoan objects found in Cyprus Four white 'lekythoi' in the National Museum at Athens are also described and some Euboean floral black-figured vases in the Museum at Chalcis There is also a discussion of the shrine of Kodros, Neleus and Basile at Athens

Work at Knossos is represented by reports on the excavation of a well containing Protogeometric and Geometric pottery and also of Protogeometric graves at Agios Ioannis Several inscriptions at Chios provide the material for a review of the local early tribal organization, and a fragment in the Piraeus Museum forms the basis for a brief study of the cult of Apollo Delios It is followed by interesting discussions of the Sibylline tradition at Delphi and of the connexion between the small clay nodules stamped with seal impressions, known as *cratulae*, and the Linear *A* accounting system The volume ends with some further consideration of architectural questions concerned with the Temple of Poseidon at Sunium. Numismatics and later work are both represented in a survey of the influence of the base silver deniers made at Tours in the thirteenth century A D on the coinage of Frankish Greece Altogether a useful volume full of good things

JOAN LIVERSIDGE

Observations and Experiments in Natural History

By Alan Dale Pp. viii + 154 + 8 plates (London William Heinemann, Ltd., 1960) 12*s* 6*d* net

THE aim of this book is to appeal to young scientists It is designed to encourage their own observations and experiments—two essentials for anyone taking up a scientific career

The book consists of notes of observations and experiments carried out by the author and others, and also suggestions for the reader's own activities Sometimes a problem is posed, and a line of experiment suggested, leaving the reader to discover the answer Wherever appropriate, broad or detailed biological facts are included

There are six chapters The first is an introduction The others cover invertebrate animals, excluding insects, insects, vertebrate animals, lower plants, higher plants As these titles suggest, a wide field is covered and, therefore, a little is learned about a lot This prevents the book from being a specialist or text-book, and, instead, acts as a stimulus This also accounts for the lack of continuity in style Each chapter is written in note form, with titles and sub-titles There are many small black-and-white figures, and eight black-and-white full-page plates

The book should interest all young people with a natural curiosity, not only those with an eye on their future

B. J G MAITLAND

Contributions to the Systematics of Oriental Termites

By M L Roonwal and P K Sen-Sarma (Entomological Monographs No 1) Pp xiv + 407 (New Delhi Indian Council of Agricultural Research, 1960.) Rs 12, 19*s*

FIVE papers dealing with the systematics of termites from the oriental region are presented here in one volume, the publication and distribution of which would appear to have suffered a delay of more than three years Related contributions by Dr Roonwal and his colleagues have continued meanwhile to appear in a variety of scientific journals, resulting in some confusion in the chronological sequence of their series

Four papers are short and deal with a variety of genera in several sub-families of the Termitidae The fifth paper, comprising 181 pages and 46 plates, is a revision of two genera of Kalotermitidae, *Kalotermes* and *Neotermes*, in which 29 species are re-described, measured in considerable detail and fully illustrated, and a further six species described as new In addition a number of lectotypes have been designated, since it was formerly the more usual practice to give a series the status of co-types It is noted that in some instances the lectotype selected is the only specimen at the authors' disposal, and would not appear to have been chosen from a series of co-types

This revision of two important genera of oriental dry-wood termites is a valuable contribution to the literature of the Isoptera, reflecting credit on the authors and the Indian Council of Agricultural Research, which financed the work It will be of much practical assistance to entomologists working in the region, and beyond, on the biology and control of these insects W V Harris

Ornamental Trees for Garden and Roadside Planting

By S A Pearce Chapters on Diseases by Derek A Reid, and Insect Pests by Joyce van Konynenburg Pp 195+94 photographs (London. W H and L Collingridge, Ltd , 1961) 35*s* net

THE author, who is on the staff of the Royal Botanic Gardens, Kew, in writing this book enjoyed the advantages of being able to refer to one of the finest collections of living trees

He has succeeded in passing on to his readers his expert knowledge, for this well-produced book contains in its sixteen chapters most that nearly all those interested in trees for ornamental purposes should require to know when selecting the right tree to plant in the right place. Having made this selection, advice is given on the correct planting of a tree and its after-treatment, including an excellent chapter on dangerous trees and how to deal with these, with some useful information on a tree owner's liability.

Ninety-four good black-and-white illustrations and nine helpful line drawings are included The student, however, who refers to the book may be a little disappointed in the absence of a good annotated diagram of a cross-section of a complete tree-trunk to illustrate the chapter on "Life of a Tree" and the omission of a paragraph on the *p*H of soils in the chapter entitled "Knowing your Soil". In keeping with the high standard reached by the author when dealing with the practical aspects of growing trees are the six chapters devoted to descriptive lists of these.

He is to be commended in arranging for the specialists Derek A Reid and Joyce van Konynenburg to contribute the authoritative chapters on "Diseases" and "Insect Pests of Trees" F P Knight

Cork and the Cork Tree

By Dr Giles B Cooke (International Series of Monographs on Pure and Applied Biology Division Botany, Vol 4) Pp. xii+121 (London and New York Pergamon Press, 1961) 50*s* net

CORK from the bark of the cork oak (*Quercus suber*) of southern Europe has been used by man from very early times and has been of importance commercially in Europe over a very long period In spite of the advance of synthetic materials the demand for cork does not lessen, probably because natural cork has a combination of unique properties not to be found in other materials A good idea of the manifold uses of cork in the modern world may be obtained from a perusal of this book The author was previously director of research of a large crown cork and seal company in the United States and has obviously made a close study of cork and its many modern applications

Last century, the cork oak was introduced to cultivation in many other parts of the world where the climate seemed suitable, often through the agency of Kew No lasting success or commercial development resulted from this, however, and southern Europe and north Africa continue to meet the world demand for cork Interesting details are given in the book of early planting of the cork oak in the southern United States and of a recent project to stimulate further planting there There is also up-to-date and useful information on the cultivation and treatment of the cork oak in Portugal and on production and trade in cork in that country—the world's largest producer The book contains chapters on the physical properties, chemical composition, and the manufacture of cork articles, and the many forms of composition cork so much used to-day F N Howes

Studies in Paleobotany

By Prof Henry N Andrews, Jr With a chapter on Palynology by Charles J Felix Pp xii+487 (New York and London John Wiley and Sons, Inc , 1961) 94*s*

THE appearance of a new and up-to-date book about fossil plants is of rare occurrence In the event, a special welcome must be accorded to *Studies in Palaeobotany*, for Prof Andrews writes with great clarity and his text is accompanied by numerous excellent illustrations, many of which are completely new or reproduced from publications not easily available to the majority of readers The larger part of the volume is devoted to a systematic survey of the major groups of vascular plants, but there are separate sections dealing with more general aspects such as the evolution of the seed, Palæozoic and Mesozoic floras, fossil plants of the polar regions, and palæobotanical techniques There is also a section on bryophytes, and Charles J Felix has contributed a most useful chapter on the specialized topic of palynology

Prof Andrews argues in favour of a polyphyletic classification of the vascular plants, but many would not agree that all the evidence on which his arguments are based is sufficiently convincing As one example, there may be noted the importance attached to *Aldanophyton*, the supposed lycopsid of Cambrian age Very little is really known about this fossil, and there is no proof of its affinities, still less that it was a genuine vascular plant It is true that the Lycopsida and Psilopsida were already co-existent during the Silurian, but there is no evidence as to which appeared first or whether they represent quite separate lines of evolution as polyphyletism demands To me, it seems that the more conventional outlook, which regards the *Rhynia*-type as having provided the ancestral stock for the other groups of vascular plants, is still not seriously challenged

Two errors need to be noted Fig 9–2*A* is not a reconstruction of *Calamophyton bicephalum* but of *C primaevum*, and on p 416 the Cathaysian flora is incorrectly stated to have overlapped the Angara province when, in actual fact, the reverse was the case Alan Wesley

Introduction to a Submolecular Biology

By Albert Szent-Gyorgyi Pp xi+135 (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1960) 5 dollars

FOR some twenty years Prof Szent-Gyorgyi's interest has been in possible mechanisms by which the reactions in cells are co-ordinated in metabolism and in the transfer of energy He has successively viewed this central problem from various physical points of view, first, the common-energy level or continuum theory, then the triplet state (in *Bioenergetics*), and now, in this new little book, the theory of charge-transfer complexes Once again, the possible catalytic effect of water is emphasized, and the author's lucid and enthusiastic prose is reinforced by photographs of the colourful events which happen when various solutions of donors and acceptors are mixed and frozen The results of extensive molecular orbital calculations by the Pullmanns are included, and serve as the backbone of the discussion, which considers the topics of drug action, adenosine triphosphate, the thymus gland and the living state There are growing numbers of scientists interested in electron mechanisms in biology who will find this book most stimulating, and a source-book of problems for some years to come

D D ELEY

The Falkland Islands

By M B R Cawkell, Dr D H Maling and E M Cawkell Pp xii+252+16 plates (London Macmillan and Co , Ltd , New York St Martin's Press, Inc , 1960) 18*s* net

THE relatively little-known Falkland Islands have had a most eventful history since human occupation reached them Their initial discovery is still somewhat obscure, in spite of active research by the more politically minded writers of South America In the present work, which is a worthy successor to that of the late Miss V E Boyson, the many facets of the islands are carefully described, although sometimes with less enthusiasm than others This volume proceeds systematically from 'discovery', through the early and later developments to administration and the role of the church and the school The more scientific aspects of the islands, the climate, vegetation, geology and structure, and bird life are admirably discussed and give the serious reader a very clear insight into the many problems of the islands The selected bibliography which appears at the end of the book is of great assistance in following up any specific subject more closely This volume should be read by those who are interested in the far-flung parts of the British Commonwealth, since it is clearly shown that the Falkland Islands is a well-developed colony R J ADIE

Water Supply

Economics, Technology, and Policy. By Jack Hurshleifer, James C de Haven, and Jerome W Milliman Pp xii+378 (Chicago University of Chicago Press, London Cambridge University Press, 1960) 7 50 dollars, 60*s*

THIS is an interesting but highly critical account of the problems of water supply in the United States approached through the eyes of two economists, Prof J Hurshleifer of the University of California and Prof J W Milliman of Indiana University, aided by a physical chemist, J C de Haven The work has been made possible through the Rand Corporation as part of a research programme

The authors believe that many water supply professionals are living in an artificial world of their own creation without respect for economic principles and rationality The present and approaching shortage of water and the proposed remedies are examined in the light of this belief Many of the conclusions reached are as a result highly controversial Much of the substance of the book will, however, be of considerable interest to those concerned with problems of the supply of water in other parts of the world Questions of over- and under-investment, financial returns on outlay, pricing, water in relation to other economic commodities, local regional and national organization and control, technological advances, and the legal position so far as water is concerned are all critically considered

A great deal of blame is laid by the authors on the imperfections in water law in the United States, where water rights are not clearly defined and cannot be transferred with ease as are rights in land and minerals, etc As a result it is argued that the economic market processes that ordinarily direct resources to uses that maximize their productivity do not operate

The establishment of clear property rights in water poses, of course, difficult problems Water is sometimes a transient resource, sometimes in store, sometimes above and at other times below ground, sometimes even unwanted But increasingly it is becoming a scarce resource in both semi-arid and humid areas, and capital will be increasingly invested to satisfy the public demand for more water The plea of this book is that this capital should be wisely invested with due forethought and on sound economic principles W G V BALCHIN

Population Redistribution and Economic Growth, United States, 1870–1950

By Simon Kuznets, Ann Ratner Miller, and Richard A Easterlin (Memoirs of the American Philosophical Society, Vol 51) Pp xiv+289 (Philadelphia American Philosophical Society, 1960) 5 dollars

THIS is the second volume of a three-volume project designed to link various indexes of economic growth to the redistribution of American population, under the direction of Prof Dorothy Thomas and Prof Simon Kuznets In the first volume, which appeared four years ago, the difficulties of collecting and adjusting comparable time series of economic data for individual years since 1870 were described, and the validity of the estimates discussed. The present volume consists of three monographs, dealing respectively with the labour force in different States, with the regional growth of income and with the changing distribution and structure of economic activity

In each of the three monographs there is noted a process of convergence of inequalities between individual States Labour force participation-rates (that is, the proportion of the population in gainful employment), income per head, and structure of manufacturing all show this trend The authors are content to describe what has happened, and do not attempt to theorize about the future, nor do they suggest that the process of convergence that they describe was a necessary condition of growth in the past 80 years

The third volume will deal with the role of migration and the interrelations between economic and demographic variables The whole project promises to be an important contribution to the study of American economic history and development E GREBENIK

Advances in Enzymology and Related Subjects of Biochemistry

Vol 22 Edited by F F Nord Pp v+567 (New York Interscience Publishers, Inc , London Interscience Publishers, Ltd , 1960) 105*s*

THE twenty-second volume of this useful series contains three articles on metabolic topics, two about the mechanism of action of enzymes, one on practical techniques, two on more biological topics, and one on pure chemistry

The sections of metabolism reviewed are the synthesis and hydrolysis of sulphate esters (by A B Roy), the biochemistry of sulphonium compounds, particularly with regard to transmethylation (by S K Shapiro and F Schlenk), and the biosynthesis of cholesterol (by G Popjak and J W. Cornforth) The last-mentioned review follows appropriately the review on carotenoid synthesis in the previous volume

An important article by D E Koshland on "The Active Site and Enzyme Action" summarizes the methods which may be used to label and identify the active centre of an enzyme, as well as putting forward some conclusions about the chemical mechanism of enzymatic catalysis S. Shifrin and N O Kaplan discuss the binding of coenzymes by enzymes, principally in cases where this may be studied by spectroscopic methods

The genetic control of enzyme activity, and the induced synthesis of enzymes, are considered in articles by J. R. S Fincham and H O Halvorson respectively These two articles emphasize the increasing interest in 'enzyme biology'

Two articles are of great practical importance to the practising enzymologist F Turba gives a valuable account of the purification of enzymes by column chromatography, with many well-documented examples J Baddiley and N A. Hughes give an up-to-date account of the chemical methods now available for the synthesis of nucleotide coenzymes and their analogues E. C. WEBB

Röntgenstrahlinterferenzen

Von Max von Laue Unter mitarbeit von E. H Wagner Dritte, neubearbeitete und erweiterte auflage Pp x+476 (Frankfurt am Main: Akademische Verlagsgesellschaft 1960) 75 D M

IT is always interesting and instructive to read a book written by the founder of a subject and to see how he considers that it has developed since it began Laue's book has, of course, been a standard work for many years and most other text-books have been based on it, either directly or indirectly Modern treatment of diffraction theory, for example, is much nearer to Laue's treatment than to the more vital and productive, but less clearly rigorous, treatment through Bragg's law

It is interesting, and not a little salutary, to see the difference between Laue's treatment of X-ray diffraction and that of British authors He justifies this third edition by stating that a great deal of progress has recently been made in research on the structure of crystals , yet this section of the book looks curiously old-fashioned, with its diagrams of diamond, graphite and fluorspar. The author's interests lie much more in diffraction by imperfect structures—liquid crystals, temperature-affected lattices and deformed crystals—than in the structures in which workers in Britain are mainly interested The names that appear frequently in our text-books—Bernal, Lonsdale, Hodgkin, etc —are scarcely mentioned in this book, but the elegant diffraction work of Hosemann and Renninger is given considerable prominence

It is sad to think that Laue's death in an accident has withdrawn the founder of the subject from among us and that he will not be present next year at the fiftieth anniversary celebrations of his great idea in Munich This book will serve as a constant memorial to him H LIPSON

Modern Physics

By M. S Smith Pp ix+254. (London Longmans, Green and Co , Ltd , 1960) 15*s* net.

THIS is a lively and well-written account of the way physics has developed in the past sixty or seventy years The author has a refreshingly original style and has attempted to convey the spirit of the investigations he describes as well as the essential detail , he has avoided the rather dreary repetition of standard diagrams and tables that so many text-books adopt

He is, however, rather unrealistic in claiming that it will serve as an introduction to the subject for sixth formers and undergraduates , it can scarcely yet be claimed, for example, that a detailed consideration of Schroedinger's equation is merely introductory The book is much more likely to be useful to the more mature physicist who wishes to have a readable survey of atomic and nuclear physics and who may wish to have some help in straightening out his ideas for presentation to others

Moreover, the book scarcely justifies its title , it contains nothing of solid-state physics, biophysics or modern developments in optics Admittedly a book of this size and modest cost could not be expected to be so general, but the title ought to have been more specific

The book is attractively produced and misprints and mistakes seem to be few But it was copper sulphate, not zinc sulphide, that was first used to diffract X-rays (p 40) ; the field of a dipole is inverse cube, not inverse fourth-power (p. 72) , and the word 'anticipate' is incorrectly used on p 80 H LIPSON

Laboratory Management and Techniques

By J. A. Edwards Pp xvi+207. (London · Butterworth and Co (Publishers), Ltd , 1960) 35*s*.

THE author makes clear in his introduction that this book does not pretend to deal with the higher problems of laboratory administration as this subject has been so adequately covered by E. S Hiscocks in his excellent book (*Laboratory Administration*, London, 1956) A reading of Mr Edwards' book, however, reveals that he too is dealing largely with administrative matters The essential difference appears to be one of point of view Mr Edwards' conception of laboratory management is that of a laboratory steward This conception is, in my opinion, better suited to the organization of teaching laboratories than to industrial and research laboratories The value of the contents of the main part of the book to all laboratories is nevertheless indisputable and quite independent of the organization-level from which it is viewed There are six parts to the book, dealing with the new laboratory, laboratory organization and maintenance, accident precautions, special and auxiliary units, purchases and records, and staff problems and human relations These parts are subdivided and filled with information and advice on design, organization, equipment and documentation This information and advice is of a kind which is obviously based on a wide experience of practical laboratory management and has rarely been recorded in an accessible form

Stores organization and fire precautions are particularly well dealt with The special and auxiliary units include the radioactive materials laboratory, lecture theatre, photographic processes, workshops and library

Those who occasionally import apparatus or chemicals will welcome the chapter on Customs and Excise procedures. This chapter deals also with applications for industrial methylated spirit, duty-free spirit and permission to use stills It is admirably concise and informative

The book is well produced and illustrated It will be of great value to all whose duties include the provision of the ways and means of scientific endeavour E I JOHNSON

Lehrbuch der Organischen Chemie

13, neubearbeitete und erweiterte Auflage Von Prof Paul Karrer Pp xx+1080 (Stuttgart Georg Thieme Verlag, 1959) 60 D M

ORGANIC chemistry has undergone a great transformation both in extent and depth since Prof Karrer's classic text-book first appeared in 1927, and much of this change has come about during the ten years that separate the last English from the new German edition of this work Prof Karrer has given recognition to this fact by inviting a group of authorities to revise and enlarge the existing text and to contribute a number of new chapters The general layout and the major portion of the contents, however, remain unaltered

While some of the newly written chapters, as, for example, those on conformational analysis, steroids, and amino-acids and polypeptides, are excellent, the shorter sections inserted into the old text are generally not well assimilated so that a consistent presentation fails to emerge In particular the treatment of reaction mechanisms leaves an unsatisfactory impression Throughout the book they are presented without formal consistency and the basis for their inclusion or omission is not readily apparent, alternative mechanisms are listed uncritically (Cannizzaro reaction, pinacol rearrangement, aldol condensation) and some are of an unorthodox nature (ester saponification, hemiacetal formation) Two further points of criticism force themselves on the reader's attention A good deal of up-to-date information has been included, but at times abbreviated to an extent which obscures its significance (chemistry of caryophyllene, biogenetic role of phenol dehydrogenations) On the other hand, there are some surprising omissions (mechanism of halogen and halogen acid addition to olefins, Michael addition, Bredt's rule)

Prof Karrer's book has for many years occupied a leading place among the text-books of organic chemistry Its principal virtue still lies in the generous amount of factual information to be found within its covers, but one wonders whether its value as a pedagogic text can be effectively maintained by the method that has been adopted in this latest edition K H OVERTON

Radiation Use and Control in Industrial Application

By Charles Wesley Shilling (Modern Monographs in Industrial Medicine, Vol 5) Pp viii+223 (New York and London Grune and Stratton, Inc , 1960) 6 75 dollars

IN his preface, Dr Shilling emphasizes that this book is non-technical and is intended for the person who needs only a working knowledge of the subject; in particular "the physician who must handle radiation exposure and injury cases and who must answer questions concerning the mysteries of radiation" In consequence the book has been written with a medical bias, but the author's aims have not been achieved since the treatment of the physical aspects of protection, such as shielding, instrumentation and monitoring techniques, is meagre and rather inadequate

The first section of the book covers the origin and nature of the radiations and the dose to man due to natural sources, and is followed by sections on the prevention and treatment of radiation injury, the control of radiation and the use of radioisotopes Although the treatment of each topic is, of necessity, concise, the subject-matter on the medical aspects is sufficient to acquaint the industrial physician with the various problems and to provide a basis for further reading It should be noted, however, that the control procedures are considered from the United States point of view, and British readers should acquaint themselves with the national legislation and recommendations

Some of the illustrations appear unnecessarily elementary and there are one or two errors in the text, for example, the maximum permissible concentration of radionuclides in air and water for the exposure of the entire population is given as one-tenth of the occupational exposure-level, whereas for individuals the International Commission on Radiological Protection recommends a reduction factor of one hundred However, these errors are not serious provided the book is used for general reading rather than as a text-book B E JONES

Commutative Algebra

Vol 2 By Prof Oscar Zariski and Prof Pierre Samuel (The University Series in Higher Mathematics) Pp x+414 (Princeton, N J . D Van Nostrand Company, Inc , London. D. Van Nostrand Company, Ltd , 1960) 58*s* 6*d*

THE first volume of this work was published in 1958 Now that the second volume has appeared it is possible to be much clearer on the motivation behind the subject as a whole This is buried in the history of algebraic geometry, and the authors have been careful to indicate what parts of geometry have led to the immense algebraic developments of recent years The book is very carefully written and will be an essential reference, and even a text-book, for the pure mathematician who moves or wishes to move in this field

There are three long chapters, given to valuation theory, polynomial and power series rings and local algebra In addition there is an appendix of about eighty pages containing a good deal of previously unpublished material. The contents of the chapter on valuation theory are illustrated largely by examples from the theory of algebraic function fields, and the notions of normal and derived normal models, of great importance in geometry, are introduced Geometry is seriously introduced in the chapter on rings, and includes an account of algebraic varieties in affine and projective space, together with a treatment of dimension theory, the Hilbert characteristic function and chains of syzygies The chapter on local algebra gives an account of local rings and their properties, and then makes use of these rings in the local study of algebraic and analytical varieties This study culminates in a section on analytical irreducibility and analytical normality of normal varieties

This volume, together with its predecessor, is abstract from cover to cover But the exposition is not condensed, and the work is likely to become the standard introduction to the arithmetic foundations of algebraic geometry For this reason it seems a pity that, apart from a few scattered references, there is no bibliography L S GODDARD

Reciprocals of the Integers from 1000 to 9999, with an Appendix on Mechanical Barrel-setting Calculators

By T H Redding Pp iv+42+2 plates (London Taylor and Francis, Ltd , 1960) 18s 6d net

THE actual entries are the reciprocals to six figures, multiplied by 10^6, so that each entry is divided into two blocks of three digits by the decimal point, thus facilitating transfer from table to machine The author does not say much about how the calculations have been checked, but some small sampling has revealed no error There are no horizontal rules except in the frame, so the page is fairly clean, with 1,000 entries at an opening and a thumb-index A clear modern 'equal height' fount is used, though it is scarcely as effective as the old-style 'head and tail' fount used by Comrie and Peters There is an appendix of some twenty pages, in which the nature and use of barrel-setting desk machines are described in simple terms for the novice The book should be of most value to those who are not expert at computation but have need now and then to make desk calculations. T A A BROADBENT

An Introduction to the Theory of Numbers

By Prof Ivan Niven and Prof Herbert S Zuckerman Pp viii+250 (New York and London John Wiley and Sons, Inc , 1960) 6 25 dollars, 50s

THIS compact and lucid text could be used by good sixth-form specialists or first-year honours students In the first part of the book the basic concepts and theorems are presented divisibility, primes, congruences, quadratic reciprocity, number-theoretic functions, diophantine equations, Farey series and continued fractions, the simpler properties of the distribution of the primes The last three chapters introduce more specialized topics algebraic numbers and number fields, the partition functions with the formulæ of Euler and Jacobi, and the fairly recent study of the density functions of a sequence of integers The proofs are clear and concise, but they rightly demand a certain sophistication of outlook without which the reader is unlikely to be able to see why a particular line of argument is chosen An excellent feature is the supply of exercises for the student; these range from simple corollaries on the main text to quite searching extensions of it, answers are given where appropriate A young student with a taste for number theory and a firm grasp of elementary algebra would find the book profitable reading

Elementary Logic of Science and Mathematics

By Dr. P H Nidditch Pp vii+371 (London University Tutorial Press, Ltd , 1960) 18s

THIS book has two aims to provide a detailed but elementary course in modern logic and to present basic material in the philosophy of science, covering probability and measurement, the scientific method and the construction of theories The author has succeeded well in writing a book that is both accurate, informative and easy to read About one-third of the book deals with formal logic, sentence logic is studied by means of a valuation theory (truth tables), and in terms of axiom systems The predicate calculus is developed both as an axiomatic system and as a Gentzen-type system of natural inference; some attempt is made to wed the two codifications but a full equivalence proof is wanting Among other axiom systems presented are Boolean algebra and a theory of probability Definitions are given with great care, there are numerous historical references and a good collection of examples, with solutions or hints for solution

The method used in the second part of the book is largely that of judicious quotation, the great scientists are allowed to speak for themselves and there is no attempt at criticism or comparative study, but there is a valuable selection from original sources

R L GOODSTEIN

Health in Industry

A Guide for Engineers, Executives and Doctors

By Prof R C Browne Pp. vii+157 (London Edward Arnold (Publishers), Ltd , 1961) 18s net

OVER the years the Nuffield professor of industrial health at King's College, Newcastle upon Tyne, has delivered courses of lectures to science, medical and technological students at the University on various aspects of occupational health The subjects have been varied and topical, and have shown concern for the health of the executive, the heavy cost of sickness absence, the importance of good design, the causes and consequences of accidents and fatigue, automatic processes and their effects on the worker and the part played by good working conditions on output Particular attention is directed to the essential precautions which must be taken in using ionizing radiations, while Prof Browne also analyses the influence of various chemical substances on the factory worker

The author has now addressed his lecture-material to all employers and managers who are, in some way or other, responsible for the industrial environment Much of it will be of interest and value, and the book should appeal to many who bear responsibility for people in industry The book could also be used in industrial health sessions during courses on industrial administration In such a book a surprising feature is the absence of all reference to skin diseases and the use of barrier creams which may cause more complaints than they cure In the section on the health of the manager, the author might also have given some practical advice about diet Many industrial executives become ill because they are unaware of the simple rules of health, although they sometimes call their complaint 'pressure of work' T H HAWKINS

LETTERS TO THE EDITORS

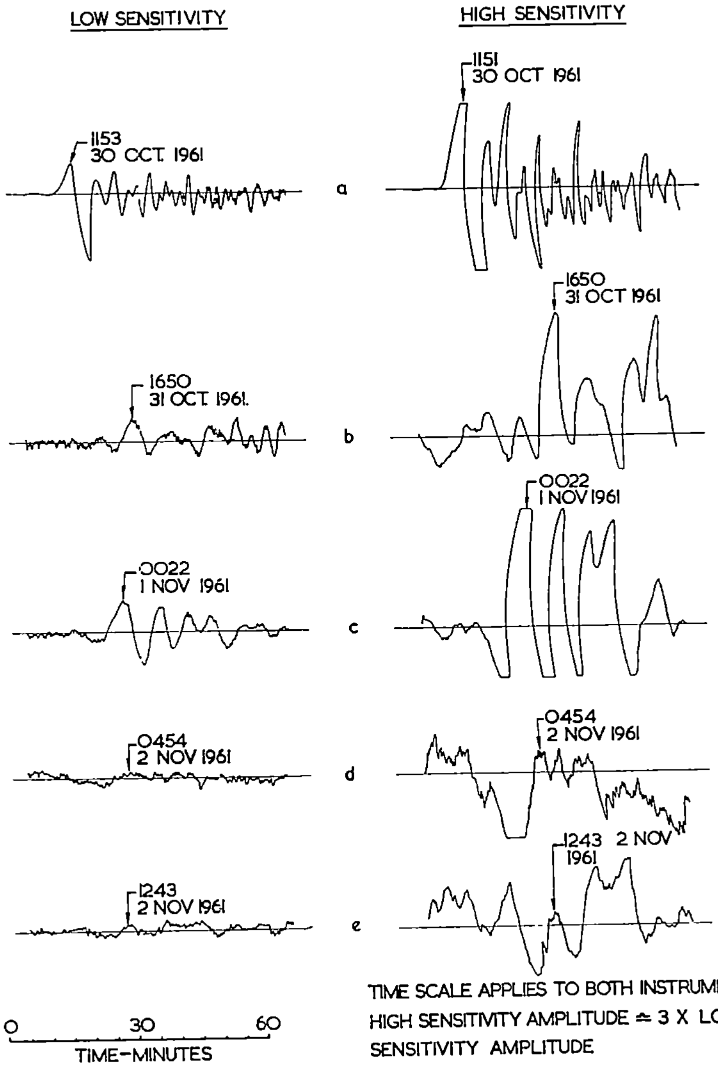
SEISMOLOGY

Microbarograph Records from the Russian Large Nuclear Explosions

DURING the recent series of Russian atomic weapon tests, microbarographs were operated at this Establishment The instruments used were purely mechanical devices having limited frequency response Excellent records were obtained from several of the larger firings at Novaya Zemlya and particularly from the 50-megaton firing of October 30. Taking the origin time as 08 33 hr from a study of the seismic signal, we saw the start of the first characteristic microbarograph record (Fig. 1*a*) 3 hr. 11 min later at 11 44 hr on October 30, subsequent to this, we obtained clear signals at approximately 16 40 hr on October 31 (Fig 1*b*), 00.10 hr on November 1 (Fig 1*c*); and 12 40 hr on November 2 (Fig 1*e*). We looked for a signal at around 05.10 hr on November 2 but could not see one against the background (Fig 1*d*)

It would appear that the waves are being successively reflected at the antipodes of Novaya Zemlya and at Novaya Zemlya, with relatively little absorption or scattering. We have re-examined our records of the 30 megaton firing on October 23 and they show similar evidence of reflexions corresponding relatively in time to those shown in Figs 1*b* and *c* for the 50-megaton firing, but with the signal to noise ratio much smaller.

Observations made on the phenomena with more refined instruments or arrays and a compilation of results on a world-wide scale could yield extremely interesting data about the Earth's atmosphere We have noticed a number of points of interest already in our brief examination of the records For example, there is a good agreement between the wave shape observed and the form one would expect from a study of the paper by Hunt *et al* (ref 1, particularly Fig 10). Brune *et al.*[2] have recently treated the problem of an elastic surface wave on a sphere and found a $\pi/2$ phase shift at each polar reflexion, our observations, although difficult of interpretation because of dispersion, do suggest a phase reversal after two such reflexions The waves diverging from the origin (Figs. 1*a*, *c* and *e*) also appear to have a simpler, more compact, waveform than the waves converging on to the origin (Fig 1*b*).



TIME SCALE APPLIES TO BOTH INSTRUMENTS
HIGH SENSITIVITY AMPLITUDE ≏ 3 X LOW SENSITIVITY AMPLITUDE

Fig 1 Microbarograph records taken at the Atomic Weapons Research Establishment, Foulness

An interesting comparison can also be made with the records obtained following the eruption of Krakatoa in 1883[3] The average time along several paths for waves to pass around Earth following Krakatoa was 36 hr. 20 min ± 10 min (*S E* 35 readings), the corresponding figure from our records being 36 hr 27 min with an accuracy of a few minutes

ASTRONOMY

The Galactic Red Shift

The recent development of the technique of resonant scattering of γ-rays, using the Mossbauer effect, appears to raise the possibility of a terrestrial test of one theory of the red shift observed by Hubble in the light coming from distant galaxies

The usual interpretation of the galactic red shift is that it is a Doppler effect due to mutual recession of the centres of the galaxies, there are, however, other possible interpretations, and among these is the suggestion by Finlay-Freundlich[1] that it is due to loss of energy by light in passage through a radiation field Finlay-Freundlich was led to this conclusion from a study of stellar red shifts and put forward the empirical relation that the fractional energy loss is proportional to the path-length and the fourth power of the temperature (energy density) of the radiation field With this simple empirical relation and using the observed stellar and galactic red shifts, he deduced a value for the average intergalactic (radiation) temperature which does not seem unreasonable on general thermodynamic grounds

Born[2] pointed out that Finlay-Freundlich's empirical relation might correspond to an otherwise unknown photon–photon interaction in which loss of energy occurs without change in direction of the photon Born showed that there was some evidence in the empirical relation for a fundamental length which ought perhaps to be part of a general description of the radiation field, and suggested that the energy apparently lost might reappear as radio emission

These suggestions by Finlay-Freundlich and Born if correct, would have very far-reaching consequences in cosmology and in the field theory of elementary particles However, several authors[3] have directed attention to certain difficulties Among other points it is asserted that the observed stellar radio emission and the change in red shift of binary stars in eclipse are too small to be consistent with the proposed theory Some of these difficulties may be very real, but bearing in mind the experimental difficulties in measuring stellar red shifts, the variety of causes which can result in both red and blue shifts, and that an otherwise unknown photon–photon interaction could result in the appearance of an entirely unknown particle, it seems worth considering the possibility of a terrestrial experiment under controlled conditions

At present, attempts are being made at Harwell and elsewhere to observe the gravitational red shift using γ-rays from iron-57 and the Mossbauer effect The resolution using iron-57 is $\sim 6 \times 10^{-13}$ It is easy to show that if the γ-rays in these experiments were allowed to pass through a radiation field of similar quality and the same order in energy density as on the surface of the Sun, extending over a distance of about a metre, the red shift expected from Finlay-Freundlich's relation is about 1 per cent of the resolution 1 per cent is not far from the expected gravitational red shifts in the present experiments in which the photons fall considerably larger distances In a practical attempt to test Finlay-Freundlich's relation, it would probably be necessary to have a radiation density times path-length such that the expected shift would be of the same order as the resolution, and although this would require a considerable effort, it does not seem entirely beyond present pulse techniques such as are used in thermonuclear work, but in this case involving lower plasma temperatures It should be a reasonably fair test if most of the energy in the radiation field lies in or near the visible region, and if the dependence on energy of the incident photon in Hubble's law can be regarded as sufficiently well established

A negative result for this proposed experiment would serve the useful purpose of removing one theory of the galactic red shift At present it would be idle to pursue in detail the various possible interpretations of an unambiguous positive result, but it may be of interest to outline one of these briefly and simply here

If we can regard our Sun as typical of about 10^{11} stars in a typical galaxy and use a value of $\sim 2 \times 10^{6}$ light years as the average intergalactic distance, it is easily shown that the average rate R_1 of release of radiation into unit volume of intergalactic space is $\sim 3 \times 10^{-29}$ erg/c c /sec The average rate R_2 of apparent loss of energy by photons in the galactic red shift is $K\rho$, where K is Hubble's empirical constant and ρ is the average energy density of radiation in intergalactic space Using a value for K of 5×10^{-18} sec $^{-1}$ and for ρ of $\sim 6 \times 10^{-12}$ erg/c c., it is clear that $R_1 \sim R_2$ Confirmation of Finlay-Freundlich's relation would justify this value of ρ and also the qualitative interpretation $R_2 = K\rho$ In these circumstances the galactic red shift becomes a vast sink which receives the radiation from the stars and transforms it into some other form, the processes involved being in approximate equilibrium at present It does not seem entirely inconceivable that at least some of the energy thus transformed might reappear eventually in space as neutrons by a net reaction involving unknown particles The hydrogen from the neutron decay would provide fuel for new stars as in Hoyle's theory of continuous creation The net effect of the entire process would be to slow up what seems at present an inevitable decline towards a universe of black dwarfs, photons and neutrinos as the hydrogen in the stars is steadily transformed to helium photons and neutrinos The amount of recycling of hydrogen by such a hypothetical process could be quite large, as most of the energy released in the net reactions in the stars goes to the photons which escape from the stellar surfaces Approximate equilibrium at present need not conflict, at least qualitatively, with the recent results of Ryle, if a 'beginning' consisting of a vast hydrogenous cloud is assumed, for in the early stages of condensation the low value of ρ would correspond now to an apparent increase in the frequency of observation of low-intensity (assumed distant) sources

OCEANOGRAPHY

Ultra-violet Absorption of Sea Water

It has been shown that at wave-lengths less than 230 mμ , the absorbency of sea water is about double that of a solution containing the same concentration of inorganic salts[1,2] We ascribe the difference to the presence of organic matter which may be the same as the blue-absorbent substances named "Gelbstoff" by Kalle[3]. We have found regional differences in the east Atlantic and English Channel, high ultra-violet absorbencies usually being characteristic of coastal water[2]. This property may be used in hydrographic surveys, and for this purpose we have measured the absorbencies of filtered samples at 220 mμ, using a 10-cm. cuvette in a Unicam *S.P.*500 spectrophotometer.

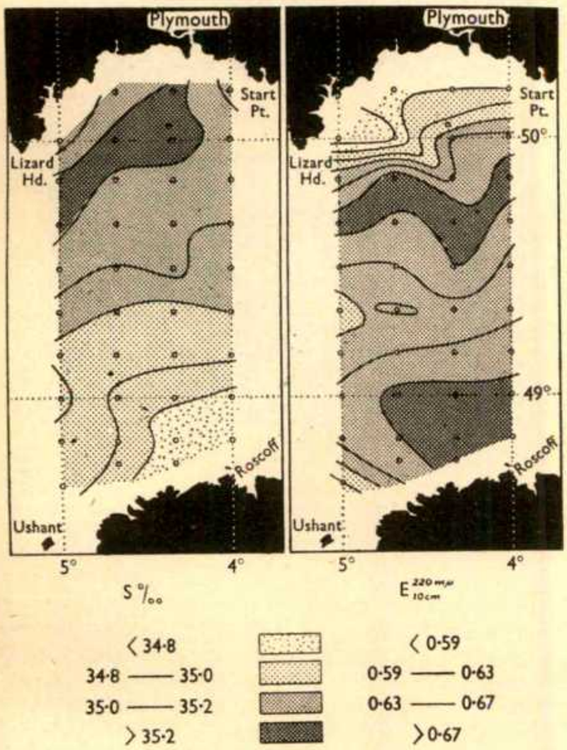

Fig. 1

Ultra-violet absorbencies of samples from 10 m. depth from a survey across the English Channel in April, 1961, are compared with salinities in Fig. 1. Water of low salinity and high ultra-violet absorption was found in the south-east corner of the area, and has presumably come down Channel on the French side, being diluted with land drainage. On the English side there is an intrusion from the west of higher salinity water of low ultra-violet absorption which we think is of Atlantic origin. This water appears to have displaced water of salinity 35·1–35·2 per mille but of higher ultra-violet absorption (*E*(200 mμ, 10 cm.) approx. 0·7) which was found off Plymouth in February, 1961 [2]. This displaced water, though indistinguishable by its salinity, is made evident as a band of high ultra-violet absorption in mid-Channel.

PHYSICS

Proposed Harmonic Generator or Mixer for Optical Frequencies

In a recent communication[1], Lainé has suggested the use of my latest form of 'cold cathode' arc harmonic generator as a mixer for obtaining beats at high microwave frequencies (that is, frequencies corresponding to submillimetre waves) between the outputs from two optical masers. I would like to comment on this proposal and suggest a simpler alternative device.

If one accepts the principle of field emission as the source of electrons from the cathode of the arc harmonic generator, then Lainé's suggestion is indeed feasible. On this basis one calculates that for the liquid platinum cathode used at present, the electron emission current density must be about 10^8 amp./cm.^{2} for a cathode spot diameter of about 1μ. The positive ion field required to produce this emission must be of the order of 10^8 volts/cm., extending over a region of only 10 Å. outwards from the cathode surface. The time-constant of the electron emission process should thus not exceed 10^{-15} sec. If the outputs from the two optical masers were first plane-polarized with the electric vectors perpendicular to the cathode surface and then focused into a region one optical wave-length in diameter (at glancing incidence) at the cathode spot then the positive ion space-charge field would have a superimposed field at optical frequencies and the electron emission should vary at the beat frequency. To produce a reasonable effect, optical fields in excess of 3×10^7 V./cm. would be required—implying maser powers of tens of kilowatts. A second disadvantage is that microwave conduction along the arc plasma (the only means of communication with the cathode spot) is shunted by diffusion spreading of the plasma in the region of the cathode, thereby imposing an upper limit to the beat frequency which can be detected. For the argon plasma at 300 atmospheres pressure this limit is about 700 Gc./s.

However, a possible field emission mixer can be made very simply. All that is required is a small drop of liquid cæsium in a glass vacuum enclosure. The energy from the optical masers should be plane polarized with the electric field perpendicular to the cæsium surface and focused into a spot about 1μ diameter striking the cæsium at glancing incidence. Strong field emission would take place for field strengths of 10^7 V./cm. which could be obtained with 3 kW. of maser power. The optical waves would penetrate the liquid surface to a depth more than an order of magnitude greater than that needed to overcome the potential barrier. During the positive going half-cycle of the optical electric field, electrons would thus be emitted in a highly 'non-linear' manner, travelling outwards for about 20 Å. in 10^{-15} sec. This oscillating charge would radiate at the beat frequency and at harmonics of the optical frequencies. As an optical frequency doubler, efficiencies approaching 1 per cent might be attained.

Further reduction of the maser power required for beat production should be possible if one makes use of the field emission studies of Martin, Trolan and Dyke[2]. They have drawn electron currents of several m.amp. continuously from a tungsten point of 0·1μ radius. If the maser output could be focused on to such an emitting point, the electron current would be modulated at the beat frequency. Some sort of magnetic focusing of the electron beam would be necessary to prevent space-charge demodulation and to enable the energy in the electron bunches to be coupled to a microwave waveguide circuit. Beat frequencies in excess of 1,000 Gc./s. should be practicable by such a method.

Detection of Spin Magnetization Variation in a Two-level Maser Oscillator

THE phenomenon of amplitude modulation in the spontaneous emission of two-level masers has been observed by several investigators[1–3], and has been the subject of a number of theoretical discussions[3–5]. The basic mechanism underlying most of the semi-classical treatments is an oscillatory transfer of energy between the spin system, in the working substance, and the cavity radiation field. In such a process the spin magnetization vector M should undergo damped, pendulum-like nutations, correlated to the modulation of the emission, between the inverted state, M anti-parallel to the steady magnetic field in the z direction, and the thermal equilibrium state, M parallel to the steady field. The quantum mechanical treatment[6] of the interaction between the spin system and the radiation field in the cavity also suggests the oscillatory behaviour of M_z. Stevens[6] further suggested that the direct observation of the variation of M_z, during an oscillation pulse, would be a more instructive test of the theories mentioned than monitoring the modulated cavity energy. Evidence confirming the suggested behaviour of M has been obtained in an induction experiment designed to detect the variations in the 'dipole' field of M_z.

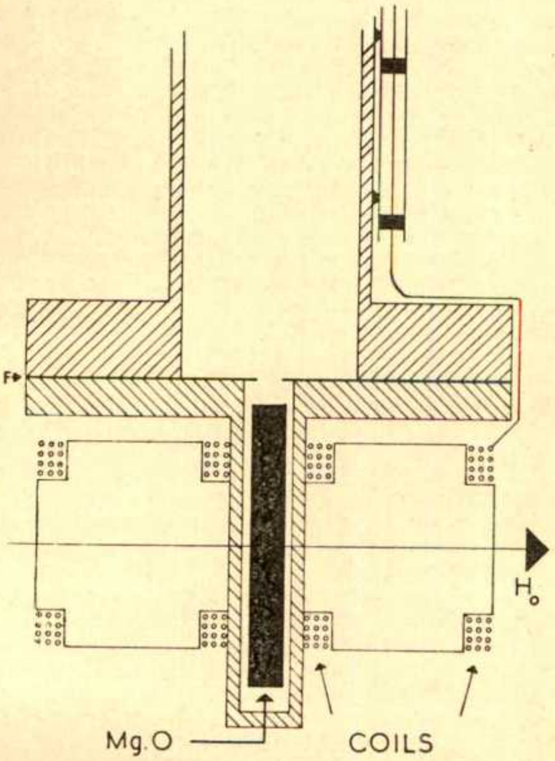

Fig. 1. Cavity with sample, pick-up coils and co-axial lead. Cavity, 0·9 × 0·1 × 0·8 in., sample, 17·5 × 2·0 mm. *F*, Silver-plated copper foil with iris to wave-guide

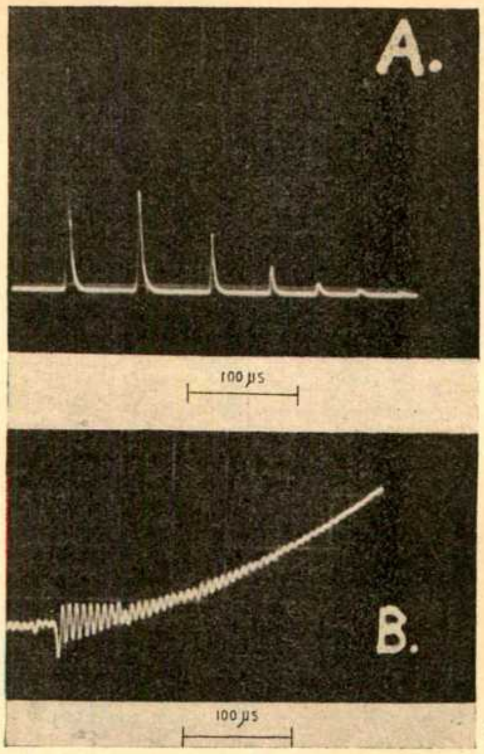

Fig. 2. *A*, Modulated emission from field-swept two-level maser: maximum power, 17 mW. *B*, Shock excitation of pick-up coils due to nutation of magnetic moment of the spin system; maximum pick-up voltage, 0·5 mV.

The maser operated in this laboratory[7] is of the field-swept type. The sample, neutron-irradiated magnesium oxide containing about 5×10^{18} spins, was mounted in a rectangular 'TE_{102}' plastic cavity resonator[8]. Oscillation pulses have been observed in which the amplitude modulation frequency was dependent upon the rate of field sweep. It was estimated that the skin-depth at these frequencies was greater, by orders of magnitude, than the cavity silver plating, so that variations of the field of M_z would not be totally confined within the cavity. Furthermore, calculations predicted that the voltage induced by this flux in an external coil, of 800 turns, surrounding the sample would be of the order of a millivolt.

Such a coil system should be balanced against pick-up from the swept field. The coil assembly used in this experiment satisfies this requirement, to a sufficient extent, and is shown in Fig. 1. The field of M_z would couple only to the inner coils, whereas the outer coils compensate for the pick-up of the swept field in the inner coils. At 1·2° K. the coils had a resonant frequency of 150 kc./s.; $Q = 4$ and a damping time constant of 60 μsec.

Maser oscillations and the corresponding pick-up voltage in the coils were simultaneously recorded on two oscilloscopes. Typical oscillograms of these recordings are shown in Figs. 2*A* and 2*B* respectively.

The oscillation envelope, shown in Fig 2*A*, is not continuous so that variations of M_z should occur only during the intermittent pulses, leading to shock excitation of the pick-up coils This was found to be advantageous because the response time of the system is too long to record completely the variations of M_z In Fig 2*B* there are shock excitations coincident with the first three oscillation pulses This coincidence was checked in a special experiment The rising base-line is due to the residual pick-up from the swept field This evidence, in support of the nutating character of *M*, is further substantiated by the fact that no effect was observed when the inverting microwave power was reduced below the level necessary to sustain maser oscillations so that only the residual pick-up was observed.

This experiment establishes the existence of variations of M_z and therefore of the nutations of *M* during emission. Further measurements of M_z will, very likely, provide useful information on the mode of operation of maser oscillators The technique described could be improved, to give detailed measurements of M_z, either by using critical damping in the pick-up coils, or by modifying the system to respond to the nutations of *M* as modulations of a high-frequency carrier wave fed to the coils

GEOLOGY

Occurrence of Magnesite–Dolomite Sediments in South Australia

In November 1960 samples of precipitating sediment were taken from a lagoon of saline water near Salt Creek in the south-east province of South Australia These were found to consist of magnesite and dolomite in about equal proportions The salinity of the water was 3 2 per cent, and analysis showed that calcium constituted a much smaller proportion of the total salts than in normal sea-water The proportion of magnesium was also lower. The *p*H was about 10

Samples were taken from the bed of the lagoon after it had become dry during the summer At the surface the proportions of magnesite and dolomite were approximately equal. At a depth of 6 in. the approximate composition was magnesite 20 per cent, dolomite 80 per cent. At 10 in , magnesite was no longer detectable and the sediment consisted entirely of dolomite This persisted to a depth of 20 in , where it graded sharply into black sulphide-bearing sands

X-ray examination of the magnesite showed that the lattice was expanded when compared with normal magnesite The lattice constants were estimated as $a_0 = 4\ 66$ and $c_0 = 15{\cdot}23$ This may be compared with the magnesium carbonate described by D L Graf, A J Eardley and N F. Shimp[1] from Lake Bonneville, U S A , which has a significantly expanded unit cell with lattice constants $a_0 = 4\ 669$ and $c_0 = 15\ 21$

Last year we[2] recorded the occurrence of hydromagnesite–aragonite sediments in a similarly situated lagoon which is about 8 miles south of the lagoon in which the magnesite–dolomite is forming This new discovery may throw more light on the origin of the magnesite–dolomite sediments of Proterozoic age in South Australia.

We believe this to be the first recorded observation of naturally precipitating magnesite–dolomite sediment.

CRYSTALLOGRAPHY

X-ray Data for the Chrome-Urania System, $Cr_2O_3\,2UO_3$

A new binary compound in the chrome-urania system has been briefly described by Borchardt[1] This compound has been prepared by mechanically mixing 78 weight per cent uranium oxide (UO_2) and 22 weight per cent chromium oxide (Cr_2O_3), pressing the mixture into pellets and firing to 1,250° C in platinum dishes The samples were reground and refired and then examined by chemical, optical, and X-ray techniques. A trace of free chrome was observed optically in mixtures where the chemical analysis indicated excess chromium over a Cr U atom ratio of 1. The X-ray powder patterns indicated only one phase

The preparations were black, with grain sizes less than 50µ Two small crystals which were recovered from the preparations showed external morphology with 6/*m* symmetry Single-crystal precession photographs, however, showed the crystals to be truly orthorhombic with three-fold interpenetrant twinning producing the pseudo-hexagonal habit Fig 1 shows the true orthorhombic lattice and its relation to the twin in the 0*kl* zone Of particular interest is the superposition of the 002 and 041 reflexions Table 1 lists the X-ray powder pattern along with the indexing based on the cell determined from the single-crystal patterns Table 2 lists the cell data and optical properties of the compound

The presence of the pseudo-hexagonal twinning suggested the possibility of a high-temperature inversion to a truly hexagonal phase Using a hot-stage furnace (Materials Research Corporation), samples were examined in air up to 1,400° C , but no evidence for the expected phase change was found. However, samples left at 1,250° C. for several days developed clusters of multiple and single crystals of the compound on the surface of the sample The crystals were yellow-brown tabular crystals with a rectangular outline Most of the crystals were twinned, producing

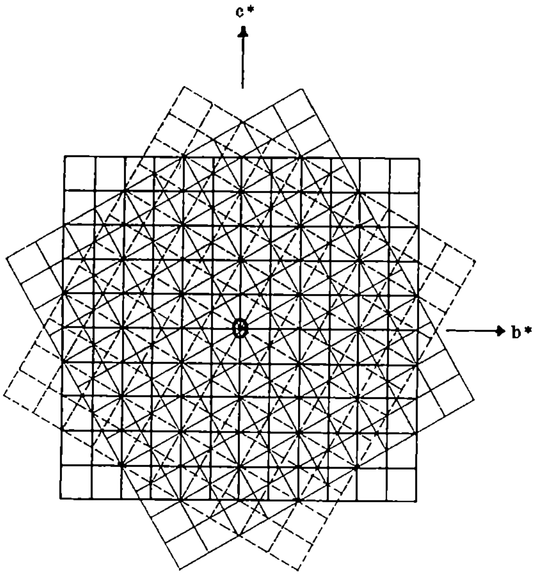

Fig 1 Relationship of the true cell in the 0*kl* zone with respect to the twinned lattices The true cell is shown as heavy lines Only points with *k* = 2*n* are included, since reflexions with *k* = 2*n* + 1 are extinct Notice particularly the superposition of 041 and 002 in different lattices

a 'cockscomb' effect around the periphery of the plates

Several crystals were examined with the precession camera The twinning was the same as mentioned above Untwinned crystals showed extinctions in *hk*0 when *h* + *k* = 2*n* + 1, *h*0*l* when *l* = 2*n* + 1, and 0*kl* when *k* = 2*n* + 1. Very weak reflexions are noted for *hkl* when *h* + *k* = 2*n* + 1, and *h*0*l* when *l* = 2*n* + 1 The extinctions indicate the unique space group *Pbcn* with a pseudo symmetry *Cmcm* The specific gravity of the crystals is greater than 3 3, which suggests either one molecule per unit cell with a calculated specific gravity of 4 18 or two molecules with a specific gravity of 8 36 One molecule would produce a problem with respect to the position of the ninth oxygen in the unit, because the space group does not allow any odd-fold special positions This inconsistency can indicate either that the oxygen is statistically distributed over 2-, 4-, or 8-fold sites, or the chemical analyses are incorrect in indicating a fully oxidized uranium The specific gravity of 8 36 is reasonable when compared with specific gravities of the components Using Vegard's law and values of 5 24 and 8 24 for Cr_2O_3 and UO_3 respectively, the calculated specific gravity for 80 weight per cent UO_3 and 20 weight per cent Cr_2O_3 is 7 64. Because deviations from Vegard's law would tend toward smaller unit-cell dimensions and high specific gravities, the values of 8 36 for two molecules per unit cell is acceptable

Structure of Asparagine Monohydrate

THE structure of asparagine has been discussed several times during recent years[1-5] A number of properties would be better explained by a ring structure than by the conventional straight-chain structure[1,2], but on the other hand, the carboxylic group had to be free[3] The structure of crystalline asparagine monohydrate has now been determined by us with X-rays, and although this does not give definite information about the structure of the molecule in solution, it does give some indications about it

* With the origin halfway between three pairs of non-intersecting screw axes

The molecules in the crystal appear to be held lightly together by several hydrogen bonds, as could be expected (Fig 1 and Table 2) First of all, there is a continuous spiral of hydrogen bonds, in the direction of the *a* axis, involving the water molecules (O_4) and the double-bonded oxygens of the carboxylic groups (O_1) Then there are three hydrogen bonds linking the nitrogen of the amino group (N_1) with different oxygen atoms O_3 (in another molecule), O_4 and O_2 The nitrogen of the amido group (N_2) forms only one good hydrogen bond with O_1, the other one, with O_2, is weaker

Of interest in connexion with the discussion whether the structure of asparagine is a ring or an

A prime indicates an atom from a different molecule

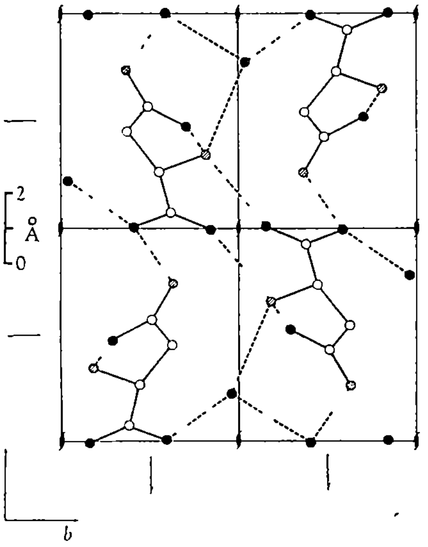

Fig. 1. Arrangement of the molecules of asparagine and water in the unit cell, as seen along the *a* axis, origin on two-fold screw axis parallel to the *a* axis. Covalent bonds and the hydrogen bonds ≤ 3.0 Å are shown. ○, Carbon; ⊘, nitrogen; ●, oxygen

open chain is the question whether there is some kind of a bond between N_1 and O_3 atoms of the same molecule. The distance between N_1 and O_3 within the same molecule is rather short (3.09 Å), but the distances between N_1 and three other oxygen atoms are still shorter (Table 2). Moreover, the difference Fourier shows hydrogen atoms in correct positions for hydrogen bonds between those atoms, but nothing between N_1 and O_3 atoms of the same molecule. Therefore, it can be concluded that there is no intramolecular hydrogen bond between N_1 and O_3 in crystalline asparagine. However, this does not rule out the possibility of a hydrogen bond in this position in solution. The structure would then be a kind of intermediate between a ring and a chain and so could account for all properties. The ring, for example, looks like the ring in proline and could therefore explain why asparagine reacts with ninhydrin in the same way as proline, and not as the other amino-acids, including glutamine[1,2].

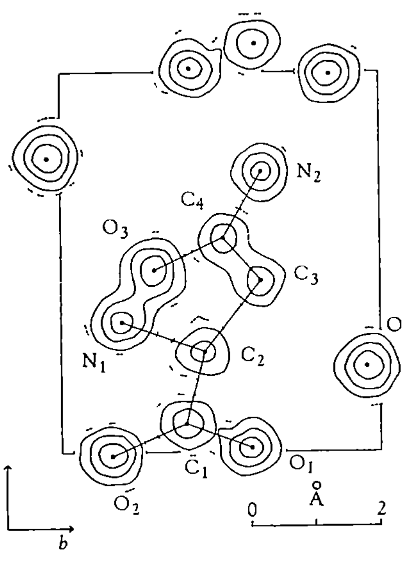

Fig. 2. Fourier projection of asparagine monohydrate on the (0*yz*) plane, after two cycles of refinement of the *y* and *z* co-ordinates. Origin as in Fig. 1

Crystallographical data about the structure are: space group $P2_12_12_1$, $a = 5.582$ Å, $b = 9.812$ Å, $c = 11.796$ Å, unit cell volume = 646.1 Å^3, four molecules per unit cell. D_0 = 1.543 gm./cm.^{3} (ref. 6). D_x = 1.543 gm./cm.^{3}.

The structure was solved using the three-dimensional sharpened Patterson. The *y* and *z* co-ordinates were first refined using the Fourier projection on (0*yz*), after two cycles giving an *R* factor of 16.2 per cent and the Fourier projection represented in Fig. 2. Then all the co-ordinates and the anisotropic temperature factors were refined using least squares programmes on the *IBM* 704. The final *R* value was 7.4 per cent.

The final atomic co-ordinates are shown in Table 1, the intra-molecular bond-lengths and the hydrogen bond-lengths ≤ 3.0 Å are shown in Table 2; these hydrogen bonds are also shown in Fig. 1. Other distances between nitrogen and oxygen shorter than 3.25 Å are N_2–O_2 = 3.02 Å and N_1–O_3 (intramolecular) = 3.09 Å. There were no intermolecular distances involving carbon atoms shorter than 3.3 Å.

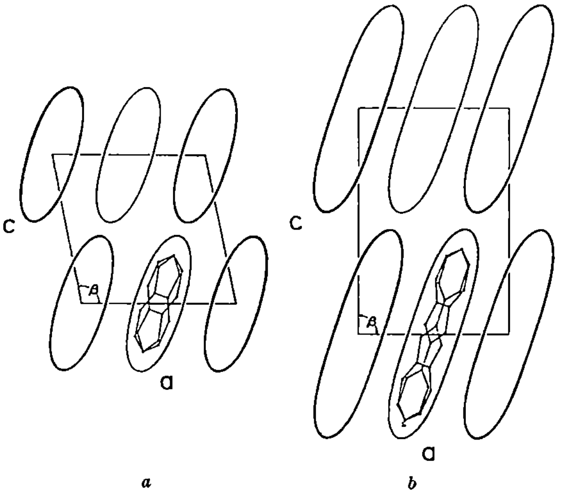
Crystal Structure of 2-Phenylazulene

AFTER a long controversy, the space group of azulene is now apparently established as the centrosymmetric $P2_1/a$, with two non-centro-symmetric molecules in the unit cell[1,2], a result which leads to a disordered structure in which successive azulene molecules in the crystal are reversed in direction at random. Two previously observed cases of random positioning, namely, between chlorine and bromine in *p*-chlorobromobenzene[3] and between methyl and chlorine in 2-amino-4-methyl-6-chloropyrimidine[4], involve atoms or groups of comparable size, and are not as surprising as is the case of azulene, where there is a rather large difference in size between the five- and seven-membered rings.

The disorder in the azulene structure complicates the precise determination of the bond-lengths in this interesting molecule. Accordingly we initiated an X-ray study of a derivative, 2-phenylazulene. Crystals of this substance were found to be monoclinic, with a = 7.92 ± 0.02, b = 5.79 ± 0.03, c = 11.81 ± 0.02 Å, β = 90°. The observed density is 1.24$_8$ gm./cm.^{3}, the density calculated for two molecules per unit cells is 1.252 gm./cm.^{3}. Weissenberg photographs taken about the three principal axes showed the absences ($h0l$) with h odd and ($0k0$) with k odd. The space group is therefore also $P2_1/a$. The lattice constants of azulene itself are[1] a = 7.91, b = 6.00, c = 7.84 Å, β = 101° 30′, and it may be noted that the values of a and b are quite similar for



a *b*

Fig 1 The unit cells of azulene (*a*) and 2-phenylazulene (*b*)

both crystals In the azulene structure, the long axis of the molecule lies very close to the direction [102] If the molecule is now lengthened by the substitution of a phenyl group in the 2 position while at the same time preserving the relation between adjacent molecules as found in azulene, then the unit cell of 2-phenylazulene is reproduced very closely In the broad sense, then, the two structures are isotypic, as may be seen in Fig 1, which shows the close relationship between the two unit cells

A trial structure for 2-phenylazulene was formulated on the basis of the above assumptions, and after trial and error adjustments the Fourier transform of two superimposed molecules yielded satisfying agreement with the observed values of F_{h0l} The electron density projected down *b*, as calculated with 48 of the 72 observed F_{h0l} together with the signs obtained from the transform, is shown in Fig 2

These considerations strongly imply that the structure of 2-phenylazulene, like that of azulene, is disordered, with the direction of the long molecular axis reversed at random A disordered structure for azulene is unexpected, but a similar structure for the 2-phenyl derivative seems even more unexpected since it suggests that the two ends of the molecule are essentially indistinguishable during the crystallization process Additional refinement of the structure is proceeding

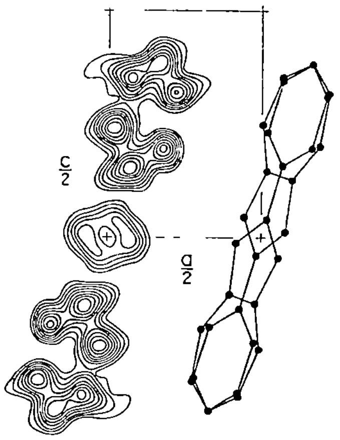


Fig. 2 Projection of the 2-phenylazulene structure on (010)

We wish to thank Prof E. Heilbronner for excellent crystals of pure 2-phenylazulene This work was supported by the U S National Science Foundation

Preparation of Single-Crystal Graphite from Melts

Single-crystal graphite demonstrates a very high degree of anisotropy between the properties obtained in directions parallel and normal to the basal plane This has generated a great deal of scientific curiosity The closest approach to single-crystal graphite so far has been in the purification and recovery of flakes of natural graphite Unfortunately, the flakes of natural graphite are imperfect, well-developed single crystals are rather scarce, especially in the larger sizes It is felt that the following technique for producing single-crystal graphite will provide basic material for work on carbon and graphite and for optical work requiring single-crystal lamellæ

We have been successful in producing single-crystal graphite by heating in a graphite crucible some titanium boride powder at 2,500° C under vacuum for 2 hr A thin, highly reflecting, flexible film forms at the surface of the melt, which may then be carefully removed from the substrate (Fig 1) Alternatively, single-crystal graphite films can be produced in graphite crucibles on the surface of melts of tungsten, zirconium carbide, nickel, chromium rhenium and molybdenum, heated at the proper temperatures

Results from X-ray diffraction of the films indicate that the material possesses the highest degree of orientation, having lattice spacings identical with the classical values given in the literature Electron diffraction observations (Fig 2) and electron optical investigations confirm the single crystallinity of the material (ref 1 and personal communication between T H Johnson and H Fernandez-Moran)

The mechanism of the technique described for graphite single-crystal growth is undoubtedly different from that in the decomposition of aluminium carbide[2],

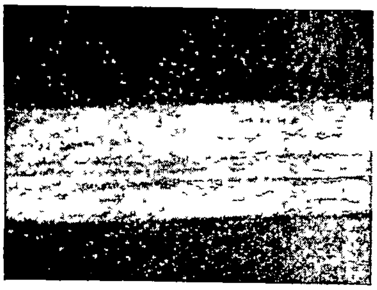

Fig 1. Cross-section of single-crystal graphite (× 500)

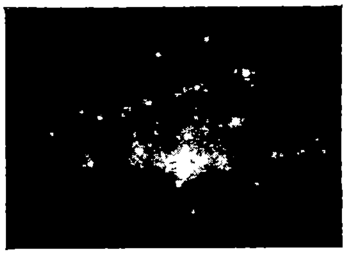

Fig 2 Reflexion electron diffraction pattern of single-crystal graphite (Radio Corporation of America *EML*-1 electron microscope, at 50 kV electrons and 50 cm distance)

in the present instance, the growth may be attributed to the formation of supersaturated solutions of carbon in the melt A detailed investigation of the mechanism in the present technique for graphite growth has begun

Definition of Rate Constant and Activation Energy in Solid State Reactions

DISLOCATIONS in alkali halide crystals doped with silver ions can be 'decorated' by a hydrogen treatment, which causes reduction and subsequent precipitation of silver[1] In the course of work on the kinetics of this solid state reaction, the problem arose of deducing the reaction constant and the activation energy without exact knowledge of the reaction mechanism, which is rarely discussed in the literature.

The definition of a rate constant k and an activation energy E for solid state reactions in analogy with reactions taking place in gases or solutions gives rise to several difficulties In the latter reactions, the rate constant is the proportionality factor between the reaction velocity and the concentration of the starting products Thus, it can be defined as the velocity for unit concentrations The dimensions of k are sec^{-1} for first-order, and $l\ mol^{-1}\ sec^{-1}$ for second-order, reactions The activation energy E is derived from the dependence on temperature of k according to Arrhenius's law

In solid-state reactions, the concepts of concentration and order of reaction generally have no significance. The reaction velocity is defined here as the change with time of the thickness of the layer of product formed, or of the weight of this layer, or of the number of gram equivalents of product formed.

Consequently, a rate constant cannot be defined in the same way as for reactions in gases or solutions If we accept the same conditions as for gas reactions, k must be independent of time and have the factor sec^{-1} in its dimensional formula, and increase with temperature according to an exponential law, from which an activation energy for the reaction could be derived It will be difficult to predict whether the latter condition will be fulfilled, since the well-known assumption for gas reactions of an equilibrium between activated and non-activated molecules according to the Boltzmann distribution is not valid here. In certain cases, other circumstances will lead to the same exponential dependence on temperature of k

This is generally the case for many reactions such as tarnishing reactions (for example, oxidations), substitution reactions and double decompositions which follow the parabolic reaction law In these cases, the velocity is governed by a diffusion process through a growing layer The velocity dx/dt is proportional to the reciprocal of x, the thickness of the layer, hence $dx/dt = k_1/x$, which leads to $x = (2k_1t)^{1/2}$ The rate constant k_1 is expressed in $cm^2\ sec^{-1}$

If we consider the weight of the layer per unit area instead of its thickness, a rate constant k_2 having as dimensions $gm^2\ cm^{-4}\ sec^{-1}$ is defined If we consider the number of gram equivalents of product formed, a new constant k_3 can be defined from the differential equation of reaction-rate with dimensions $gm\ equiv.\ cm^{-1}\ sec^{-1}$

In tarnishing reactions, the rate-constant is generally proportional to the diffusion coefficient D of one of the reaction partners in the product formed. The exponential dependence on temperature of D leads to the validity of the Arrhenius relation for the rate constant:

$$k_1 = k_0 \exp(-E/RT)$$

where E is the activation energy for self-diffusion Nevertheless, Jost[2] emphasizes that, on account of the complexity of the tarnishing process, a simple dependence on temperature of the net process often cannot be expected

The theory of Wagner[3] for the velocity of substitution reactions and double decompositions, based on the model of the closed galvanic cell, leads to an expression for k which is proportional to the specific conductivity σ of the products formed For the reaction $AgCl + Cu \rightarrow Ag + CuCl$, for example, k is proportional to σ_{CuCl} The exponential dependence on temperature of k will be a consequence of the exponential dependence on temperature of σ in solids The activation energy of the reaction will be that of electrical conduction (which is the same as for self-diffusion)

Thus, for reaction laws of the parabolic type, a rate constant can be defined in a similar way as for gas reactions, its exponential dependence on temperature included Dimensionally it is dependent on the way the reaction velocity is defined.

Consider now a reaction following the linear law, for example, tarnishing reactions when the formed layer is porous or incoherent Here, the reaction is governed by phase-boundary processes, and the velocity is independent on time

$$dx/dt = k_4 \text{ or } x = k_4t$$

The constant k_4, which is expressed in $cm\ sec^{-1}$, is the rate of the phase-boundary process (for example, chemisorption) which will generally not increase exponentially with temperature Consequently the Arrhenius relation will not be valid

In solid state reactions governed by logarithmic laws, new difficulties arise on account of the presence of several constants independent of time and dependent on temperature

Hence for solid state reaction kinetics, rate constant and activatom energy can only be clearly defined when a suitable hypothesis for the mechanism of the given reaction is available If the rate constant is defined from the experimental relation between the quantity of product formed and time, it is difficult to predict whether it will show an exponential dependence on temperature Even if this is approximately the case, the interpretation of the activation energy thus found remains dubious (see, for example, ref 4)

Suppose that no hypothesis for the parabolic law was available, and that the rate constant k_5 had been defined by $x = k_5 t^{1/2}$ The activation energy deduced from the temperature dependence of k_5 would not be E, the activation energy for diffusion, but $\frac{1}{2} E$

$$k_5 = (2k_1)^{1/2} = (2k_0)^{1/2} \exp(-\tfrac{1}{2} E/RT)$$

Moreover, k_5 has not the right dimensions (cm sec $^{-1/2}$ instead of cm ^{2} sec $^{-1}$)

Heat of Formation of the Difluoromethylene Radical

ATKINSON[1] has accounted for the products of the mercury photosensitized decomposition of tetrafluoroethylene by supposing that the excited mercury atoms (Hg $^3P_1$) are able to decompose tetrafluoroethylene to give two difluoromethylene radicals This requires that the dissociation energy of the carbon–carbon bond in tetrafluoroethylene is equal to, or less than, 112 kcal /mole Since this value is significantly smaller than the lower (125–30 kcal /mole)[2] of many values suggested for the dissociation energy of the carbon–carbon bond in ethylene, it is of some interest to obtain independent estimates of the heat of formation of the difluoromethylene radical

The fluorobenzene ion ($C_6H_5F^+$) is an abundant species in the mass spectrum of benzotrifluoride. Similarly, difluorobenzene ions are abundant in the mass spectra of fluorobenzotrifluorides This appears to be a specific rearrangement similar to that observed by Beynon[3] in the case of oxygen-containing compounds Energy considerations suggest that the most probable process in these cases involves the expulsion of a difluoromethylene radical from the trifluoromethyl group, as for example

$$C_6H_5CF_3 + e \rightarrow C_6H_5F^+ + CF_2 + 2e$$

In this case, the appearance potential ($A(C_6H_5F^+)$) of the fluorobenzene ion (13 35 eV.) taken together with the ionization potential ($I(C_6H_5F)$) of fluorobenzene (9 30 eV , cf the value of 9 20 eV from photoionization work[4]), and the heats of formation of fluorobenzene[5] (−26 5 kcal /mole) and of benzotrifluoride[6] (−138 9 kcal /mole), the heat of formation of the difluoromethylene radical is found to be equal to or less than −17 kcal /mole Thus, using the value for the heat of formation of tetrafluoroethylene[7] (−152 kcal /mole), the dissociation energy of the carbon–carbon bond in this compound is found to be 118 kcal /mole Within the uncertainties in the experimental quantities (which amount to about ± 5 kcal /mole) this is a maximum value for this quantity In a similar way the appearance potential (13 15 eV) of the *p*-difluorobenzene ion from *p*-fluorobenzotrifluoride together with the ionization potential of *p*-difluorobenzene (9 15 eV), the heat of formation of *p*-difluorobenzene (−72 2 kcal /mole, calculated from $\Delta H_f(p-C_6H_4F_2)$ (l) = −79 5 (Scott, D W, private communication), taking ΔH_v (estimated) = 7 3 kcal /mole), and the heat of formation of *p*-fluorobenzotrifluoride (assumed to be close to that of *m*-fluorobenzotrifluoride, −184 2 kcal /mole (Scott, D W, private communication)), give a further estimate for the heat of formation of difluoromethylene (−21 kcal /mole) consistent with the first value Since there is no value available for the ionization potential of *m*-difluorobenzene it is impossible to make any calculation based on the appearance potential (13 75 eV) of the ion of this molecule from *m*-fluorobenzotrifluoride

A less-certain but independent estimate of the heat of formation of the difluoromethylene radical may be obtained from some kinetic data of Atkinson and Atkinson[9], who have shown that octafluorocyclobutane is able to decompose by the process

$$c-C_4F_8 \rightarrow CF_3—CF=CF_2 + CF_2$$

The energy of activation for this process must fulfil the condition

$$E \gg \Delta H_f(CF_3CF=CF_2) + \Delta H_f(CF_2) - \Delta H_f(c\text{-}C_4F_8)$$

Atkinson and Atkinson[9] give for the rate coefficient for this reaction

$$k = 3{\cdot}9 \times 10^{16} \exp -79{,}000/RT\ s^{-1}$$

Taking the energy of activation together with the heats of formation of octafluorocyclobutane (−352 kcal /mole from the heat of dimerization[10] and the heat of formation[6] of tetrafluoroethylene) and of hexafluoropropene (−259 from Duus's results[11], and the heat of formation of tetrafluoroethylene) requires that the heat of formation of difluoromethylene is equal to, or less than, −13 kcal /mole The value quoted for the rate coefficient, however, was obtained from an analysis of the data that supposed that the quasi-stationary concentration of octafluorocyclobutane was controlled by its decomposition into two molecules of tetrafluoroethylene A fuller analysis would probably require a slightly larger energy of activation and a larger pre-exponential factor for the rate coefficient, and this in turn would require a slightly more positive limiting value for the heat of formation of difluoromethylene

Our value for the heat of formation of difluoromethylene (about −17 kcal /mole) supports the values proposed by Reed and Rabinowitch[12], and by Mann and Potocki[13]. It suggests that the radical is more stable than does the value (about −5 kcal / mole) implied by the results reported by Reed[14] from a study of electron impact processes with carbon tetrafluoride Our conclusions about the bond dissociation energy in tetrafluoroethylene are similar to those of Margrave[15], but there remain the problems of the discrepancy between the value assumed by Margrave[15] for the ionization potential of the difluoromethylene radical (11 eV) and that found by Reed[14] (13 35 eV), and of the nature of the process by which the difluoromethylene ion is formed from tetrafluoroethylene Our values for the heat of formation of difluoromethylene and the heat of formation of the trifluoromethyl radical (−115 kcal/mole) give for the carbon–fluorine bond dissociation energy in the latter radical the value 117 kcal/mole. This is a little less than that (121 kcal/mole) of the carbon fluorine bond in carbon tetrafluoride[14]

Dislocations as Active Centres in Heterogeneous Catalysis

Much work has been carried out in recent years on the relation of heterogeneous catalysis to point defects in solids or to semiconductivity We have found an example of catalysis in which dislocations play the part of the active centre in the case of copper for the decomposition of diazonium salt (Gattermann's reaction) A sample of copper, free from point defects and containing dislocations only, is obtained by annealing the cold-worked sample in an appropriate temperature-range The necessary data on annealing, a twisted sample, as given by Boas[1], are summarized in Fig 1

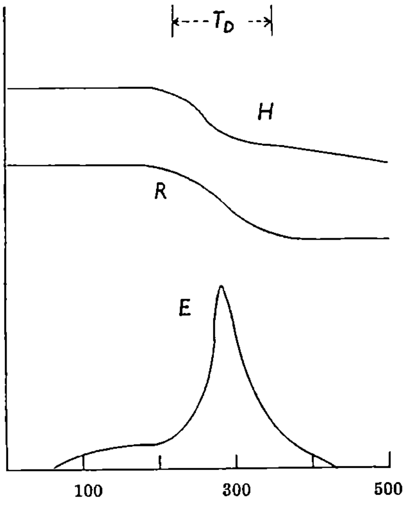

Fig 1 Changes of hardness (*H*) and electrical resistivity (*R*), and the release of defect energy (*E*) during annealing of copper samples (99 96 per cent) deformed in torsion to $nd/l = 1\ 8$, where *n* is the number of turns, *d* the diameter and *l* the length (see ref 1)

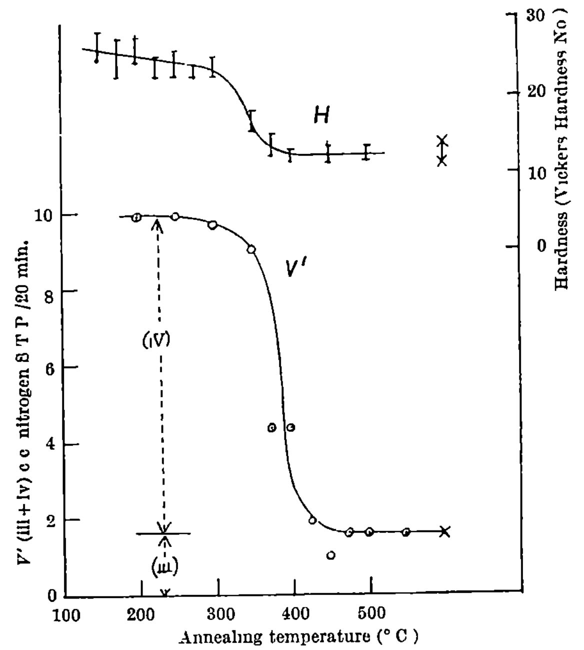

Fig 2 The heterogeneous catalytic activity at 25° (*V*′) and hardness (*H*) of copper cold-worked and annealed at various temperatures ×, Values for samples not cold-worked

In a temperature-range T_D, a sudden change takes place in hardness, in electric resistivity and in density, with the rapid release of defect energy and recrystallization[2] These phenomena have been attributed to the disappearance of dislocation in the deformed metal, because point defects produced in copper by deformation or irradiation at sub-zero temperatures disappear by annealing below room temperature

In our experiments pieces of copper wire (99 96 per cent pure) were twisted to $nd/l = 1\ 0$ after complete annealing at 550°, and then were annealed again at various temperatures The samples were washed with ammonia water and thrown into a solution of diazonium chloride, the reaction velocity was measured by the total volume of nitrogen (*V*) evolved in 20 min, the part of *V* to be ascribed to heterogeneous catalysis (*V*′) is shown in Fig 2 together with hardness of the samples Though the value of T_D is considerably influenced by impurities as well as by the degree of cold-working of different samples, the sudden and concurrent changes in hardness and in catalytic activity in the annealing temperature-range, 300–430° C, are ascribed to the disappearance of dislocations Consequently, it may be concluded that the reaction corresponding to (iv) in Fig 2 is a catalytic effect due to dislocations, amounting to 84 per cent of heterogeneous catalysis in the case shown The value of *V* consists of the rate of (i) natural decomposition, (ii) homogeneous decomposition catalysed by cuprous ion dissolved from the metal, (iii) heterogeneous decomposition catalysed by the normal surface of copper and (iv) heterogeneous decomposition catalysed by the end of the dislocation at the surface The change of surface area on annealing is considered to be negligible, because it was found that catalytically active copper powder deposited from copper sulphate solution by means of the reaction with zinc dust has almost the same adsorption capacity for methylene blue even after it is annealed at 500° and loses most of the activity

(3 2 × 10^{-7} and 3 1 × 10^{-7} mole/gm , respectively) The volume of nitrogen evolved, V, for a sample without dislocations (obtained by annealing at temperatures higher than T_D) is the sum of (i), (ii) and (iii), and the decrease in V on removing copper from the solution is the sum of (iii) and (iv) when reduced to the initial concentration of the solution, hence each value can be obtained separately For example, (i) is 4 6, (ii) 1 5, (iii) 1 6 and (iv) 8 3 c c for samples annealed below T_D as shown in Fig 2, (ii) as well as (iii) being almost constant irrespective of the annealing temperature

In the case of nickel, the catalytic activity for the hydrogenation of ethylene is greatly enhanced by rolling the metal foil, but this effect is eliminated by annealing at a temperature between 200° and 300° (ref 3). From the results of annealing experiments for deformed nickel[1,4], the evolution of energy and the change of physical properties between 90° and 320° and those between 520° and 660° were concluded to be due to the disappearance of vacancies and dislocations, respectively. Consequently, the greater proportion of the enhanced activity found by us may be attributed to point defects at the surface formed by cold-working (although the value of T_D may not be exactly the same as that with vacancies in the bulk crystal), contrary to Cratly and Granato's postulate[5] ascribing the activity to dislocations. By means of the method described, we hope to obtain some knowledge of the physical nature of the active centres in metallic catalysts

We wish to thank Dr M Kikkawa and the late Mr H Ushio for supplying us with copper samples, and Prof. H. Wakeshima for his advice

BIOCHEMISTRY

Polysaccharide Content of the Prolapsed Nucleus Pulposus of the Human Intervertebral Disk

The nucleus pulposus of normal human intervertebral disk contains the two acidic mucopolysaccharides, chondroitin sulphate and keratosulphate[1-3] During ageing an increase of collagen occurs[4] leading to a decreased ratio of mucopolysaccharide to collagen, although the absolute amount of mucopolysaccharide remains constant[4].

A recent paper by Hendry[5] has shown that the prolapsed nucleus pulposus is in fact relatively desiccated *in situ* He postulated that this was due to a loss or deterioration of the protein–polysaccharide complexes present. We have analysed a series of nuclei pulposi, from prolapsed disks, for ester-sulphate and have found that without exception these contain very low amounts compared with our measured normal specimens

The values obtained for the prolapsed nuclei pulposi are considerably lower (in most cases less than half) than values in the literature for the normal nucleus The decrease in ester-sulphate content on ageing shown in Table 1 is apparent rather than absolute, due to increase of collagen increasing the total percentage dry weight It is unlikely that all these low ester-sulphate values are only due to an abnormal increase in the collagen content of the nucleus, in fact, percentage dry weights of up to 75 per cent would be required to explain these values It seems more likely that a genuine decrease in the absolute quantity of mucopolysaccharides has occurred before or during prolapse

Table 1 Ester-Sulphate Analyses of Prolapsed Human Nucleus Pulposi at Various Ages

Age (yr.)	Ester-sulphate sulphur as percentage of dry weight
18 *f*	1 1
19 *f*	1 2
26 *m*	1 0
39 *m*	1 0
49 *m*	0 6
53 *f*	0 6

m, Male, *f*, female (free sulphate in all cases was found to be negligible)

It is seen that these results appear to favour Hendry's theory of relative dehydration of the nucleus leading to prolapse An alternative hypothesis arises which involves the possibility that the normal deposition of collagen fibrils, which with age tends to make an intervertebral disk more rigid and less likely to prolapse, might not occur so completely with a genuine deficiency of mucopolysaccharide, thus allowing the nucleus pulposus to remain a relatively unstrengthened gel Such a disk would then be the one more liable to prolapse than a normal disk of the same age group The possibility arises that the mucopolysaccharides in the surrounding annulus fibrosus may also be reduced, giving rise to more friable wall structure

The cause of the loss in acidic mucopolysaccharides is unknown, although it is of interest that we have found that all samples of nuclei pulposi contain a hitherto unreported free monosubstituted guanidine compound (Sakaguchi test and electrophoretic isolation)

Metabolism of Propionate by Homogenates of Normal Sheep Liver

Propionic acid, one of the major products of cellulose fermentation in the ruminant stomach, is of unique importance in the carbohydrate economy of the sheep[1], in addition to its presumed function as a direct source of energy Following injection of propionate into the blood-stream of a fasting sheep, there may be observed both a sharp rise in blood glucose[2], and an increase in the rate of consumption of oxygen of the animal

This communication deals with the metabolism of propionate by whole homogenates of sheep liver, prepared to retain mitochondrial respiration. Measurements were made of the rate of consumption of propionate and the rate of uptake of oxygen In addition, the nature of the products of propionate metabolism was examined, and a hypothesis is proposed which relates these findings to the mechanism of propionate metabolism by the sheep

The experimental conditions were designed to permit the measurement of oxygen consumption in an atmosphere of 95 per cent oxygen, 5 per cent carbon dioxide, by the indirect method in ref 3 The apparent solubility of carbon dioxide in the medium used was determined to be 1 57 µl carbon dioxide/µl fluid/atmosphere (37° C) Volumes of 6 ml. and 3 ml , containing 1 0 ml and 0 5 ml of a 1/7 homogenate in 0 25 *M* sucrose, were used, the high solubility of carbon dioxide in the medium permitting standard Warburg flasks to be used despite the similar gas volumes of the pairs of flasks Replicate measurements indicate a precision of ±6 per cent for oxygen consumption-rates, and ± 9 per cent for rates of evolution of carbon dioxide

It was found that propionate was not consumed in the absence of oxygen, carbon dioxide, adenosine triphosphate (ATP) (or adenosine diphosphate), or of additional cytochrome *c* In the complete medium the mean rate of propionate consumption was 2 39 µequiv. / mgm. nitrogen / hr , with a standard error of 0 15 (eighteen observations) Gas-liquid chromatography[4] of reaction products failed to demonstrate either the accumulation of other volatile acids, or the disappearance of any volatile acid other than propionic

Fig 1 shows the relationship between the rate of propionate consumption and the rate of uptake of oxygen, only those experiments having been included in which it was demonstrated that the rate of consumption of propionate was identical in both 6-ml. and 3-ml volumes This criterion is necessary because only under these conditions is the measure of oxygen consumption-rate valid, and because the rate of propionate consumption was found to be extremely sensitive to loss of carbon dioxide from the medium during the initial manipulations The regression derived from the results shown in Fig 1 yields a value of 39 1 ± *SE* 1 0 µl. oxygen/µequiv of propionate consumed ; this is equivalent to the complete oxidation of half the propionate metabolized

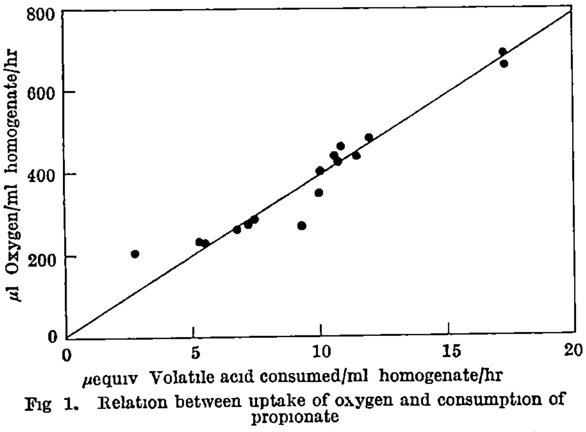

Fig 1. Relation between uptake of oxygen and consumption of propionate

Experimental conditions were as described in the legend to Table 1, but with varying homogenate concentrations Propionic acid consumption was measured as steam-volatile acid consumed, volatile acid being distilled from constant volume and titrated under nitrogen

The only detectable products of propionate metabolism were carbon dioxide and the dicarboxylic acids succinic acid, fumaric acid and malic acid Lactic acid production, presumably from endogenous glycolysis, was identical in the presence and absence of propionate and no consistent effect was found on the small endogenous ketone production. The dicarboxylic acids were detected following exhaustive extraction with ether, by paper chromatography using four different solvent systems[5-8]. Methyl malonic acid could not be detected in these reaction mixtures, but has been found to accumulate when propionyl coenzyme A and labelled carbon dioxide are incubated with sheep liver homogenates in which mitochondrial structure has been disrupted by homogenizing in *p*H 8 *tris* buffer for 5 min in a Servall Omni-mixer

Table 1 shows the rates of uptake of oxygen by homogenates respiring in the presence of succinate, L-malate and propionate These rates are consistent with an oxidation of propionate via L-malate, and since it has also been found that the stimulation in the rates of oxygen consumption caused by propionate and L-malate is not additive, it is inferred that propionate oxidation proceeds via the complete oxidation of L-malate

Table 1 OXIDATION OF PROPIONATE, SUCCINATE AND MALATE BY SHEEP LIVER HOMOGENATES

Exp No	µl. oxygen/mgm nitrogen/hr.			
	No substrate	propionate	succinate	malate
25	48	100	168	103
26	27	60	125	83
27	28	76	125	85
35	50	110	173	120

Oxygen consumption was measured by the indirect method of Warburg in 6 0 ml and 3 0 ml volumes of a medium having the following composition KH_2PO_4 3 6 × 10^{-3} *M*, K_2HPO_4 1 64 × 10^{-3} *M*, $NaHCO_3$ 2 50 × 10^{-2} *M*, KCl 9 0 × 10^{-2} *M*, $MgCl_2$ 5 × 10^{-3} *M*, sucrose 4 0 × 10^{-2} *M*, ATP 1 3 × 10^{-3} *M*, cytochrome *c* 1 1 × 10^{-5} *M*, substrate 5 0 × 10^{-3} *M* and liver protein contributing 3–4 mgm nitrogen/6 0 ml After gassing with 95 per cent oxygen, 5 per cent carbon dioxide for 9 min in the bath at 37° C , flasks were equilibrated for 10 min and buffered isotonic substrate added from the side-arm to a final concentration of 5 0 × 10^{-3} *M* Manometric readings were taken at 6-min intervals for 36 min , oxygen consumption-rates being computed over the final 30 min Homogenates were prepared from the livers of freshly killed sheep in 0 25 *M* sucrose in a glass homogenizer immersed in ice water Nuclei and cell debris were removed by centrifuging at 600*g* for 10 min in a refrigerated centrifuge

In attempting to explain the quantitative link between the rates of consumption of propionate and uptake of oxygen, two possibilities have been considered, either of which may be expressed by the reaction sequence shown in Fig 2, in which it is proposed that the complete oxidation of 1 mole of L-malate leads to the activation of 2 moles of carbon dioxide.

One means by which this could be achieved is by the maintenance of a stable rate of oxidative phosphorylation Assuming the activation of propionate to release pyrophosphate[9], and the fixation of carbon dioxide to release orthophosphate[10], then the P/O ratio necessary to sustain the rate of propionate uptake found would be 6/7 (0 86 ± 0 02, cf Fig 1), a curious value, maintained with unusual precision

A more probable explanation may lie in the direct transfer to propionyl coenzyme A of carbon dioxide derived from oxidation of the malate carbon skeleton.

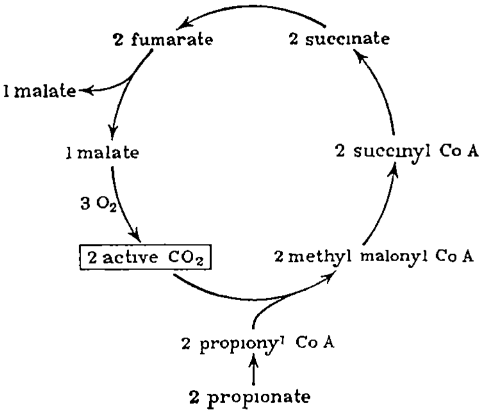

Fig 2 Proposed mechanism of propionate metabolism by sheep liver

The recent observation of Swick and Wood[11] of the direct transfer of the oxalacetate β carboxyl group to propionyl coenzyme A to form methyl malonyl coenzyme A in cell-free extracts of *Propionibacterium shermanii* supports this hypothesis Swick and Wood pointed out that such transferable carboxyl groups exist in methyl malonyl coenzyme A and malonyl coenzyme A in addition to oxalacetic acid, and that these molecules have a common structural feature in that the active carbon dioxide group is derived from a carboxyl group β to a carbonyl function which is in turn adjacent either to a second carboxyl group or to a coenzyme A moiety During complete oxidation of malate via pyruvate and the tricarboxylic acid cycle, both oxalacetic acid and oxalosuccinic acid lose carboxyl groups of this nature With this in mind, work on the mechanism of propionyl coenzyme A carboxylation in sheep liver mitochondria is being continued

The relationship between uptake of oxygen and consumption of propionate by liver homogenates is of considerable interest in relation to the *in vivo* synthesis of glucose from propionate The observations reported here demonstrate a mechanism whereby precursors of carbohydrate are derived from propionate at twice the rate at which propionate may be oxidized

We thank Dr H R Marston for suggesting this work, which was undertaken as part of a general investigation of cobalt deficiency in sheep

Binding of *RP2-L*—a Nuclear Protein of Neoplastic Tissues—to Deoxyribonucleic Acid

Recent work in this laboratory has indicated that the incorporation of radioactive amino-acids into nuclear proteins, especially the acid-soluble nuclear proteins, represents an important metabolic pathway in transplantable rat tumours[1-3] The acid-soluble nuclear proteins obtained from rats injected with L-lysine-U-^{14}C were chromatographed on carboxymethyl-cellulose columns[4] after the acid extracts had been dialysed against 0 5 *N* acetic acid The cellulose columns (sodium form) had been equilibrated against 0 05 *M* sodium acetate buffer, *p*H 4 0 Gradient elution was used with *N* formic acid followed by 8 *N* formic acid All procedures were carried out at 4° C The resolving power of this method provided specific chromatographic patterns for protein distribution and distribution of radioactivity for the acid-soluble nuclear proteins of the Walker tumour and various tissues of the tumour-bearing rat The chromatograms of the acid-soluble nuclear proteins from the various non-tumour tissues contained one to three radioactive peaks with relatively low specific activities The chromatograms of the nuclear extracts of the Walker tumour, and a number of other malignant tumours, contained a radioactive peak which was not found in any of the growing or non-growing[4,5] non-tumour tissues studied

In the present work, deoxyribonucleoproteins were extracted with water from cell nuclei, isolated from the Walker tumour and liver of tumour-bearing rats[6-10] The deoxyribonucleoproteins were then precipitated by making the medium 0 15 *M* with respect to sodium chloride (ref 10) L-lysine-U-^{14}C (10 μc.) was injected 1 hr before the tissues were excised[3 4] The nuclei from 3–5 gm of tissue were blended in 50 ml distilled water 6 times for periods of 10 sec. The temperature was maintained at 4° C The sample was centrifuged at 2,000*g* for 30 min and the nuclear residue was washed twice with 50 ml distilled water. To the combined supernatant solutions containing the deoxyribonucleoproteins, solid sodium chloride was added to make a final concentration of 0 15 *M* and the sample was kept in the cold laboratory (4° C for 1 hr) and was again centrifuged at 2,000*g* for 30 min after the supernatant solution (the 'nuclear sap') was decanted The white deoxyribonucleoprotein precipitate was stirred with 0 25 *N* hydrochloric acid for 20 min and then was centrifuged at 100,000*g* for 30 min After centrifugation of the supernatant nuclear sap at 100,000*g* for 30 min, 2 *N* hydrochloric acid was added to the combined supernatant solutions to make a final concentration of 0 25 *N* hydrochloric acid Of the total deoxyribonucleic acid (DNA) found in the various fractions, 80–90 per cent was in the residue which was precipitated after the acid extraction of the nucleoproteins The remaining 10–20 per cent was in the water-insoluble residue No DNA was found in the supernatant solutions in which the concentration of sodium chloride was 0 15 *M* In this communication the DNA-bound protein is referred to as 'chromosomal protein' and proteins of the supernatant fractions are referred to as proteins of the nuclear sap

The optical densities at 280 mμ of a standard volume of 3 0 ml of extracts of chromosomal proteins of tumour and liver respectively were 0 30 and 0 20 per gm wet weight of tissue The optical densities of the acid-soluble proteins of the nuclear sap of tumour and liver respectively were 2 0 and 1 0 The

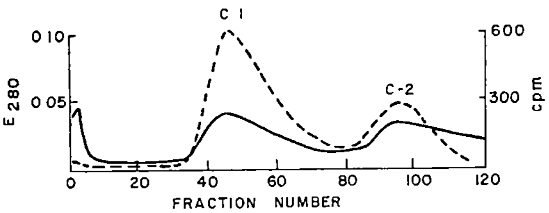

Fig 1 Chromatographic patterns of both radioactivity and protein-concentration for chromosomal proteins of the Walker 256 carcinosarcoma The data are averages of three experiments Gradient elution was employed with N formic acid followed by elution with 8 N formic acid at fraction 80 Solid line, optical density, broken line, radioactivity

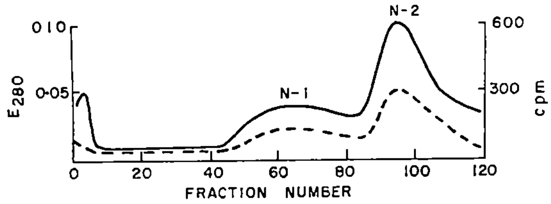

Fig 2 Chromatographic patterns of both radioactivity and protein-concentration for nuclear sap proteins of the Walker 256 carcinosarcoma The data are averages of three experiments Solid line, optical density, broken line, radioactivity

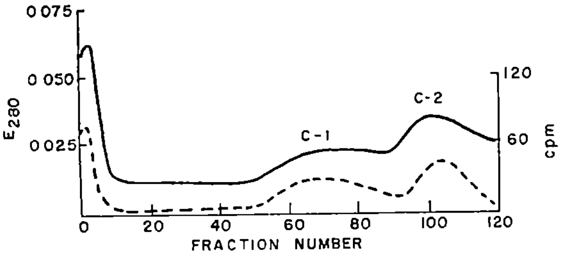

Fig 3 Chromatographic patterns of both radioactivity and protein-concentration for chromosomal proteins of the liver of the tumour-bearing rat The data are averages of three experiments Solid line, optical density, broken line, radioactivity

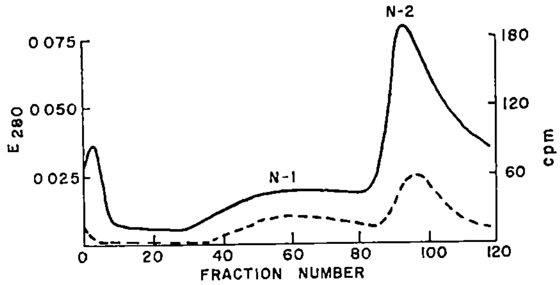

Fig 4 Chromatographic patterns of both radioactivity and protein-concentration for nuclear sap proteins of the liver of the tumour-bearing rat The data are averages of two experiments Solid line, optical density, broken line, radioactivity

extracts obtained were chromatographed on carboxymethylcellulose as described above, after dialysis against 0 5 N acetic acid

In order to maintain maximum resolution of the proteins, extracts of 'chromosomal proteins' from 4–6 gm of tissue and extracts of nuclear sap from 2–3 gm of tissue were chromatographed

The patterns for the protein distribution and radioactivity in the chromatograms of 'chromosomal' (DNA-bound) proteins and the cationic proteins of the nuclear sap of tumour and liver are presented in Figs 1–4 The specific activity of the chromosomal proteins of the tumour was much higher than that of the other extracts The most radioactive proteins, that is C–1 of the tumour (Fig 1), were eluted with N formic acid in the same position as $RP2$–L, the protein peak found in neoplastic tissues Like $RP2$–L, the specific activity of the protein of peak C–1 was high (10,050 c p m /E_{280}) In addition, the protein of peak C–1 of the tumour contained 35 per cent of the total counts of the total acid extract Since C–1 or $RP2$–L was concomitantly dissolved and precipitated with DNA, and was not found in the preparations which did not contain DNA, these data indicate that C–1 or $RP2$–L is a DNA-bound chromosomal protein

The finding that a protein, found thus far only in neoplastic tissues, is synthesized rapidly on the chromosomes suggests that the genetic change in tumour cells may be reflected in production of abnormal chromatin These findings may provide a tool for investigation of the nature of the abnormalities of the DNA in neoplastic cells

Isolation and Identification of Rhamnose from Rabbit Skin

THE presence of neutral sugars such as galactose, mannose and L-fucose in several animal sources such as glycoproteins or blood group substances is well known[1] but L-rhamnose has not been previously reported as a constituent of mammalian tissues

Skin from rabbits (1–2 years old), injected with glucose-U-^{14}C, was treated with a depilatory, cut into strips, frozen in liquid nitrogen and ground into a fine powder in a Wiley mill The powder was homogenized with water in a Virtis-45 homogenizer at maximum speed for 30 min , the extract centrifuged at 5,000 r p m. for 30 min , the supernatant filtered through glass wool and lyophilized to yield 0 10–0 20 gm /10 gm of milled powder

Hydrolysis of the lyophilized material with 0 25 N hydrochloric acid for 30 min.–1 hr , followed by methyl pentose analysis[2] of the supernatant, indicated that the lyophilized material contained 1–3 mgm. methyl pentose/100 mgm of material The presence of rhamnose was suggested by the relative mobility of reducing substances in butanol/pyridine/water (6 4 3), butanol/acetic acid/water (4 1 5) and isopropanol/water (9 1)[3-6] The latter solvent gave the best separations from other methyl pentoses such as fucose

250 mgm of the water-soluble fraction were hydrolysed as above (1 hr) and salts removed on a 'Dowex 50 H^+–Dowex 1', HCO_3^- mixed-bed resin

The resulting solution was concentrated, banded on acetic acid washed Whatman *BMM* paper, and chromatographed for 17–20 hr at room temperature in a solvent system of 9 parts isopropanol : 1 part water Visualization of reducing substances with silver nitrate on a parallel strip showed three spots, one of which had a mobility corresponding to that of rhamnose. The appropriate area was eluted with water, and an aliquot assayed for radioactivity in a Packard 'Tri-Carb' liquid scintillation counter using dioxane/anisole/dimethoxyethane (6 1 : 1) as solvent and 2,5-diphenyl oxazole 1,4-*bis*-2-(5-phenyloxazolyl) benzene (40 . 1) This fraction was found to contain carbon-14. 50 0 mgm of crystalline L-rhamnose hydrate was added as carrier, the solution concentrated to a thick syrup and allowed to crystallize for 2 hr –3 days The crystalline rhamnose obtained in several experiments was identified by infra-red spectrometry and contained 85–98 per cent of the total radioactivity present in the water eluate of the chromatogram, the specific activity was not lowered on recrystallization

The fine structure of the rhamnose-containing compound is at present unknown and will be the subject of subsequent investigation

Formation of Histamine and Histamine-like Substances from Histidine by Quartz Dust

It has been shown[1] that quartz dust is capable of participating in a number of oxidative and hydroxylative reactions The present communication reports the production of histamine, from the interaction of quartz dust with histidine, and the chromatographic isolation of additional products of this reaction, namely, imidazole–carboxylic acids from the lungs of guinea pigs treated with quartz dust

Attention was first directed to a possibly harmful effect of histamine in silicosis by Uspensky *et al* [2], who in 1957 reported an overall increase of this material in the lungs of silicotic animals over that in the lungs of normal animals, and ascribed the toxic action of quartz to its release of histamine in excessive amounts into the tissue

It has now been shown in this laboratory that quartz dust, when treated with the amino-acid *dl*-histidine base, produces several imidazole-like substances, one of which has been identified as histamine both chromatographically (descending unidimensional system using Whatman No 1 paper, *n*-propanol / 0 2 *N* ammonia (3 1), spraying reagent· Pauly's sulphanilic acid reagent) and biologically (guinea pig uterus) Similar chromatographic products were obtained when hydrogen peroxide was treated with histidine under the same conditions. The reaction of quartz with histidine may be of the oxidation-reduction type due to the peroxidative properties of quartz reported earlier[1] Deamination and partial decarboxylation of histidine were obtained by Holtz[3] by treating it with ascorbic acid and glutathione in air or oxygen, or by passing oxygen and hydrogen through a medium containing histidine and metal catalysts

In the present work a yield of at least 5 μgm histamine (0 1 per cent) was obtained by alternatively shaking and incubating 1 gm of quartz dust with 5 mgm. histidine in 5 ml water at 37° for 5–10 days After centrifugation, the dust was washed with ethanol–hydrochloric acid and this washing was added to the supernatant mother liquor before concentrating to about 0 2–0·5 ml The reaction was accelerated and the yield was increased when the medium was made slightly alkaline with sodium carbonate This was also found when the contents of the vessel were allowed to dry out during shaking When carried out in acid solution (hydrochloric acid), which also stabilized any histamine formed, the reaction took place rapidly at 85–90° C. Iron ions in the medium either retarded or inhibited histamine formation· this finding agrees with that of Holtz[3]. Furthermore, acid-washed quartz produced more histamine from histidine than did untreated quartz with an iron content of 0 03 mgm /gm

The asbestos dusts, crocidolite and chrysotile, and mine dust (a dust collected from ventilation shafts in a Witwatersrand gold mine) were also able to produce histamine from histidine in the presence of sodium carbonate, but the relatively inert dusts, kaolin and talc, were without effect These latter have already been reported[1] to have low or negligible oxidizing or hydroxylating abilities.

Dusts producing histamine also gave rise to a second Pauly-positive material which was detected chromatographically (orange red, R_F value 0 1–0 14), and which was later identified by the use of other solvents as a complex spot consisting of a number of imidazole carboxylic acids Glutamic acid, a well-known degradation product of histidine[4], was also produced.

Quantitative assays of lung tissue for histamine indicated that this reaction between active dusts and histidine might occur *in vivo* The assays were carried out on the wet, unperfused lungs of two groups of four guinea pigs, the animals of one group were exposed for 140 days to a superfine quartz dust (80 per cent of particles less than 2μ) at a concentration of 25,000 particles/c c for about 7½ hr a day; the other group were controls. A mean value of 8 7 mgm /100 gm. dried tissue for histamine (as the dihydrochloride) was obtained for the lungs of the group treated with quartz dust compared with 5 4 mgm /100 gm. for the control group This represents a 29 per cent increase of histamine in the dusted groups of animals. In a further group of animals dusted for a period of 180 days, the increase was of the same order (namely, 31 per cent) Chromatographic analyses of the trichloroacetic acid extracts of lungs after adsorption with activated charcoal and elution with ethanol / hydrochloric acid (2 1) showed the presence in the dusted group of the Pauly-positive spot described above (R_F 0 1–0 14), but not in the control sample even when much higher concentrations of lung extracts were used This spot, however, was absent when lung extracts of animals treated with dust for only 70 days were chromatographed. On further resolution in other chromatographic solvent systems, the imidazole carboxylic acids listed in Table 1 were identified In addition, traces of urocanic acid were identified in lung extracts from

Table 1 R_F VALUES OF MATERIALS FOUND IN TWO SOLVENT SYSTEMS

Solvent system	Material	R_F value
n-Butanol/acetic acid/ water (50 12 50)	Imidazole pyruvic acid	0 24
	Imidazole lactic acid	0 27
	Imidazole acetic acid	0 34
	Hydroxymethyl imidazole	0 41
Isopropanol/ammonia (0 88)/ water (160 8 16)	Imidazole pyruvic acid	0 04
	Imidazole lactic acid	0 07
	Imidazole acetic acid	0 06

animals treated with dust, this might be a hydrolysis product of its choline ester, murexine, a substance producing pronounced pharmacological effects Very small amounts, or none, of these materials were detected in extracts from the lungs of the control group The enzymatic conversion of histidine to some of these degradation products has been reported by van Thoai[5], who treated L-amino-acid-oxidase with histidine

The evidence obtained from these experiments suggests that not only can quartz produce histamine from histidine *in vitro*, but also a number of other derivatives, some of which are biologically active The presence of these substances in the lungs of animals exposed to quartz dust but not in controls makes it seem likely that the *in vitro* course of events shown above may occur *in vivo*.

The possibility of histidine as a basic substance being adsorbed on quartz dust after this has entered the lung tissue, and its continual transformation into small amounts of histamine and other potentially harmful substances might over a long period of time be of importance in the pathogenesis of silicosis

I wish to thank the director of this Unit, Dr H S Gear, for facilities extended to me during this work, the senior biochemist, Dr J S Harington, for valuable assistance with the preparation of this manuscript, and Mrs Lippuner, of the Department of Pharmacology, University of the Witwatersrand Medical School, for carrying out the biological assays.

Influence of *p*H and Urea on the Ultra-violet Fluorescence of Several Globular Proteins

RECENT work by Weber[1-3] has shown that the ultra-violet fluorescent spectra of globular proteins differ from those predicted for the summation of the independent contributions of their aromatic amino-acid constituents Those examples investigated which contained tyrosine, but no tryptophan, showed a tyrosine emission spectrum, but with a reduced quantum yield Those containing both tyrosine and tryptophan showed an emission spectrum predominantly resembling that of tryptophan alone, with an emission maximum in the range 320–350 mμ The present communication will be concerned solely with proteins of the second category

These include a protein showing a reversible structural transition at extremes of *p*H (bovine serum albumin), a protein the internal structure of which is probably invariant to *p*H (lysozyme), and a protein undergoing a simultaneous denaturation and unfolding into a random coil at neutral *p*H (pepsin) An Aminco-Bowman spectrofluorometer, equipped with a thermostatted cell-holder, was used for all measurements Unless otherwise specified, the temperature of measurement was 24° C The wave-lengths of excitation and of emission were 290 mμ and 340 mμ, respectively

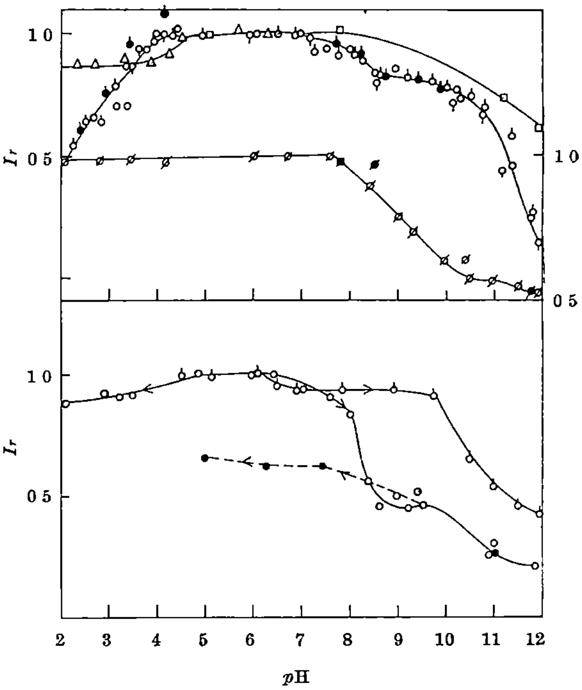

Fig 1 Relative fluorescence intensities Upper ⫯, Armour bovine plasma albumin in water, ○, bovine plasma albumin fraction from diethylaminoethyl cellulose column (containing 0 24 mole —SH per mole albumin in water, △, same, in 2 0 *M* potassium chloride, □, same, in 8 *M* urea, ⫰, bovine plasma albumin fraction from diethylaminoethyl cellulose column (containing 0 98 mole —SH per mole albumin) in water, o, Armour crystalline lysozyme in water The curve is displaced downward by 0 5 unit with respect to the albumin curve The right-hand ordinate applies Lower ○, Armour crystalline pepsin in water, ⫰, same, in 0 2 *M* potassium chloride The protein concentration is 0 1 gm /l in each case The filled circles represent reverse points The ordinate is the fluorescence intensity relative to that at *p*H 6, which is the starting point for either acid or alkaline titration The wave-lengths of activation and of emission are 290 mμ and 340 mμ, respectively

All the proteins under examination had an emission spectrum characteristic of tryptophan, with a maximum in the range 320–350 mμ The dependence of fluorescence intensity on *p*H was very different for the various proteins All these had, however, the common feature of undergoing a pronounced quenching in the *p*H region 9–12 (Fig 1)

In the cases of bovine serum albumin and lysozyme, the reverse curve obtained on back titration from alkaline *p*H showed no major deviation from the forward curve, in harmony with expectations arising from the reversible character of the alkaline titrations for these proteins

The presence of urea in high concentration (10 *M*) appears to reduce the magnitude of alkaline quenching at a given *p*H for bovine serum albumin considerably

At *p*H's acid to *p*H 5 the various proteins examined showed a wide divergence of behaviour Lysozyme and native pepsin, the macromolecular properties of which appear to be invariant to pH in this range, show a small decrease in intensity. However, bovine serum albumin, which is known to undergo a structural transition in this zone[6] of pH, shows a reversible quenching of fluorescence if the titration is carried out in the absence of added electrolyte. In 2·0 M potassium chloride the acid quenching is reduced somewhat, presumably because of the suppression under these conditions of the inflation of the molecular domain occurring at low ionic strengths[6].

In addition to the acid and alkaline quenchings bovine serum albumin showed a small but definite quenching in the region pH 7·0–9·0 (Fig. 1). It is of interest that spectral evidence exists for a minor structural change in this zone[7]. Katz and Klotz have reported changes in calcium ion binding properties in this region[8].

Pepsin, which is known to undergo an irreversible denaturation, accompanied by a gross molecular disorganization at a critical neutral pH zone[6–9], shows somewhat different behaviour[9]. The emission increases slightly between pH 2 and pH 5. The onset of irreversible denaturation, which occurs at pH 7·5–8·5 in the absence of added electrolyte, is reflected by a sharp drop in fluorescence intensity (Fig. 1). If 0·2 M potassium chloride is present the extent of the drop is greatly reduced. In either case a second region of decrease is noted in the zone of tyrosine ionization, pH 9–12.

A complete interpretation of this fairly complex behaviour will certainly require the disentangling of several effects in each of the examples considered. It is likely that the ionized form of tyrosine is the only group the absorption spectrum of which overlaps sufficiently with the tryptophan emission spectrum to permit an important degree of radiationless energy transfer[4,5]. From the behaviour of pepsin and bovine serum albumin, it is clear that the intensity of fluorescence of globular proteins is a function of their molecular organization and can be expected to be influenced by molecular events which alter the secondary or tertiary structure and thereby modify the environment of the fluorescent group.

Bovine plasma albumin fractions were obtained through the courtesy of Dr. R. Hartley.

Note added in proof. In subsequent work with another lysozyme preparation a minor (10 per cent) quenching was found between pH 6 and pH 2. The acid branch of the lysozyme curve of Fig. 1 may thus require revision.

Retinene-1 in Insect Tissues

Attempts to detect vitamin A in insect tissues have been largely unsuccessful. One species of cockroach (*Blatella germanica*) has been raised for generations on a diet devoid of vitamin A and carotenoids[1]. As no vitamin A could be detected in oil extracted from these insects, it appeared that the vitamin played no part in their metabolic processes. Other workers[2] similarly have reported their inability to detect vitamin A in Blattidae. Acetone extracts of the locusts *Schistocerca gregaria* and *Locusta migratoria migratorioides* gave negative tests for the vitamin[3], while extracts of the heads of fruit-flies, grasshoppers, and dragonflies also have been reported to be lacking in vitamin A (ref. 4). No dietary requirement for vitamin A could be demonstrated for either *Drosophila melanogaster*[5,6] or *Anopheles labranchiae atroparvus*[7].

However, extracts of the pupæ of the silkworms *Bombyx mori* and *Antherea pernyi* have been reported[8,9] to contain vitamin A, while Goldsmith[10] recently has demonstrated that extracts of the heads of honey-bees contain retinene-1, and that a visual pigment of this insect is a rhodopsin compound analogous to vertebrate visual pigments. Wolken *et al.*, in a recent report[11], have announced the detection of retinene-1 in house-flies.

In the experiments reported here, the presence of retinene-1 in the honey-bee and the house-fly was confirmed, and the compound detected in extracts of the following insects, which represent many major orders of insects: *Paracolletes fulvescens* (Hymenoptera), *Locusta migratoria* (Orthoptera), *Uropetala carovei* (Odonata), *Cicindela tuberculata* (Coleoptera), *Nyctemera annulata* (Lepidoptera), *Cutelia sedilotti* (Orthoptera).

Adult specimens of these insects were collected locally, and in some cases were preserved by deep freezing, and in others were killed by decapitation and immediately experimented on. The heads were separated from the rest of the body and the two tissues extracted separately. In the case of the bees, the legs were removed to avoid excess carotenoids from pollen. The tissues were ground with anhydrous sodium sulphate and the mixture extracted with anhydrous acetone. This treatment releases carotenoids, vitamin A and retinenes from proteins. The resulting extracts were evaporated and the residues taken up in petroleum ether. On chromatography on aluminium oxide columns, yellow absorption bands developed, and were eluted with acetone–petroleum ether mixtures (4 per cent, 10 per cent and 40 per cent v/v). Each fraction was evaporated and the residues taken up in a small amount of chloroform. A Carr-Price reaction with saturated antimony trichloride solution in chloroform, and acetic anhydride, was conducted on each fraction. One fraction from insect heads of each species gave a noticeable blue coloration and an absorption maximum at 664 mμ.

These observations demonstrate the presence of retinene-1 in the heads, and its absence in the bodies, of each of the insect species investigated. It is a reasonable conclusion, considering the known functions of retinene in vertebrates and in other invertebrate phyla, that the retinene detected occurs in the insect eyes and is involved in their visual processes. It is of considerable interest that no vitamin A alcohol was detected in the above experiments. Moreover, the amounts of retinene present in the insect heads was very small and about 10 gm of tissue was necessary to give a satisfactory positive result

These findings indicate that the rhodopsin type of visual pigment occurs in many insects This being the case, the experiments[1,5-7] in which insects have been raised on diets devoid of vitamin A and carotenoids are difficult to understand Perhaps there is some other insect visual system that does not involve retinene, or alternatively, and more likely, perhaps the insects raised in these nutritional experiments were visually defective

PHYSIOLOGY

Oscillatory Flow in an Air-filled Elastic System

A REPORT has been published by me[1] of the study of oscillatory flow in a fluid-filled elastic system, using an 'oscillator' It has now been discovered that the same device (Fig 1) will oscillate, in stationary wave motion, when there passes through it a stream of air, instead of water or blood

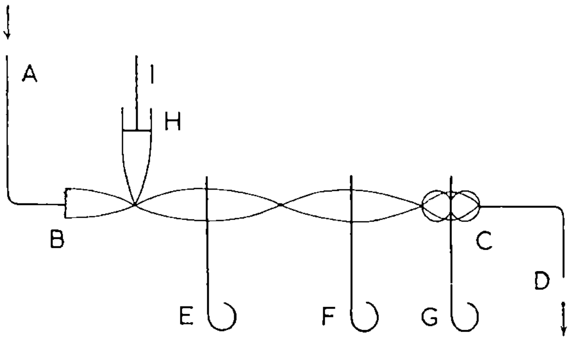

Fig 1 Diagram to show the component parts of the 'oscillator'

Air compressed to a pressure of about 0 7 kgm /cm^2 is delivered from a tank of which the outlet is controlled by a screw valve The air is led by the rigid tube (*A*) to the elastic tube (*BC*), which is composed of latex rubber, 0 7 cm in diameter and 97 cm long The other end of *BC* is connected to the rigid outlet tube (*D*) Extensions of the torsion springs (*E*) and (*F*) compress the elastic tube at the sites of antinodes, the extension of the torsion spring (*G*), at the site of a pseudo-stationary node, the loops being as shown The waves are both transverse and longitudinal, belonging to two systems of differing length, namely, 1–2 cm and approximately 75 cm As the wave-length approaches the diameter of the tube, the particles of air describe more or less circular orbits The correct position of the springs may be determined previously, by running water through the model from a reservoir, as already described At this stage, the quarter-wave matching stub (*H*) is useful in suppressing stationary waves at the proximal end of *BC* one end of the stub is connected to a node, as shown, the other closed by the piston (*I*)

Using compressed air, the model can be made to produce a great variety of noises and sounds, including musical notes Oscillations of low frequencies resemble purring noises at high frequencies, squealing noises result Harsh sounds occur, resembling those made by parrots or chirruping sounds such as those of other birds

Tuning is effected by altering the pressure of the springs on the elastic tube In the case of the spring (*G*), however, tuning is also effected by moving the point of application with relation to the junction of *BC* and *D* Tuning is particularly sensitive at this site The effect of transverse compression appears to be analogous to the application of a 'shunted inductance' the greater the pressure, the higher the frequency and conversely Movement of the point of the spring, in relation to the end of the tube, alters the length of the system of short stationary waves The segment of elastic tube involved can be regarded as a cavity resonator, so that the effect is analogous to that of altering the 'capacitance' The shorter the wave-length, the higher the frequency and conversely Increase of 'resistance', brought about by closing the screw valve which controls delivery of air, causes the pitch of the note, or noise, to rise and conversely

The spring (*G*), pressing on the elastic tube, produces a shape closely resembling that of one vocal cord It may be assumed that, in the larynx, the wave-lengths of the vibrating expired air approach the dimensions of this structure and of the related cavities The system of long waves of the tube (*BC*) is then related to the vibrating columns of air in the trachea and bronchi during speech and the apparatus can be regarded as an analogue for study of the mechanism of phonation

The model suggests that, in addition to approximation of the vocal cords, elevation and depression of the larynx when the pitch of the voice rises and falls, respectively, are also of significance in tuning In phonation, moreover, the action of the thorax and lungs is that of velocity modulation of the expelled air, whereas that of the larynx is to effect density modulation of this air

Hormonal Control of the Development of the Thymus of the Fœtal Rabbit

THAT the fœtal adrenal is physiologically active has been firmly established, for example, Jost and Jacquot have shown its importance in the development of fœtal liver glycogen[1-3] That the adrenal itself is influenced in its development by a structure or structures within the skull—generally assumed to be the hypophysis—has been demonstrated in the rabbit[4,5] and rat[6,7] by fœtal decapitation, following which there is a considerable reduction in the adrenal by full term Since it is well recognized that in the adult animal adrenal hormones have a thymolytic action, it was considered possible that the development of the fœtal thymus might be influenced by the fœtal adrenals To test this hypothesis rabbit fœtuses were decapitated at 20–21 days of development and the thymus glands were weighed when the fœtuses had reached almost to term The results were clear cut, for in the operated fœtuses the thymus on average was 72 per cent heavier than in their litter mate controls[5]

The operation of decapitation of the fœtus, performed to remove the pituitary, does not affect the development of the fœtus, as judged by gross weight[8,9] The operated fœtuses, together with their litter mates, continue to develop within the uterine cavity for a further eight days It was thought that the resulting increase in thymus weight might be the result of the reduction in the development of the adrenals secondary to the decapitation of the fœtus which abolishes fœtal pituitary secretions, in particular, fœtal adrenocorticotrophic hormone (ACTH)[6]

However, it could be argued that the increase in size of thymus in the decapitated fœtuses might be due to the absence of other fœtal pituitary hormones apart from ACTH, or even to the removal of some other structure in the head, such as the brain or the pineal To investigate this point further, it was decided to inject ACTH into the fœtus, at the same time as the decapitation was performed, to replace the fœtal ACTH, and to investigate the effect of this combined procedure on the development of the adrenals and the thymus A long-acting preparation of ACTH in gelatin was used to avoid having to repeat the injection into the fœtus

Eight fœtuses were decapitated by the method described by Jost[10] between the 21st and 22nd day of development, and 0 2 ml of 'Acthar' gel was injected subcutaneously in the interscapular region of each fœtus just before it was returned to the uterus The fœtuses were recovered after a further seven days of intra-uterine development, by Cæsarian section, and the adrenals and thymus removed and weighed to the nearest 0 1 mgm The weights were expressed per 100 gm of body-weight, and were compared with 15 litter-mate controls

The results are shown in Table 1 There is no significant difference between the weights of the decapitated fœtuses injected with ACTH and the litter-mate controls The adrenals were found to be slightly larger in the decapitated fœtuses injected with ACTH compared with the control fœtuses, but this difference is not significant The thymus of the experimental fœtuses showed no significant increase in weight over the thymus of the controls

These results provide confirmation of the view that the increase in weight of thymus found in decapitated fœtuses[5] is due to the retarded adrenal development, caused by the absence of fœtal ACTH following the decapitation

Table 1 THYMUS AND ADRENAL WEIGHTS OF THE RABBIT FŒTUS FOLLOWING DECAPITATION AND INJECTION OF ACTH

Fœtuses	No	Age at investigation (days)	Body-weight (gm) headless	Adrenal weights (mgm / 100 gm)	Thymus weight (mgm / 100 gm)
Decapitated + ACTH (at 21–22 days)	8	28–29	23 4±1 8	25 4±4*	275 3±13*
Controls	15	28–29	23 0±1 5	19 6±1*	261 6±13*

* These differences are not significant

These findings also provide an explanation for some of the endocrine abnormalities present in the human anencephalic fœtus It has long been known that the pituitary of these fœtuses is very small or absent[11], and the small adrenals and large thymus reported in this human abnormality[12] are likely to be secondary to the deficiency of fœtal ACTH

I am indebted to Prof A Jost for his help with the technique involved in intra-uterine surgery of the fœtus, to the Medical Research Council for a grant for apparatus, to Armour Laboratories for a supply of ACTH, and to Prof E W Walls for his help and encouragement in this work

Luteinizing Hormone in Persistent Vaginal Œstrus

THE placement of experimental lesions in the anterior part of the hypothalamus may be followed by persistent vaginal œstrus in the guinea pig and rat Such animals possess relatively small ovaries which have no fresh corpora lutea Various attempts have been made to explain these effects in terms of an altered output of gonadotrophins by the pituitary gland The original view that the secretion of luteinizing hormone was blocked[1] was supported by Van Dyke *et al* [2], who found that in animals with persistent œstrus induced by lesions, the ovarian interstitial tissue showed a high lipid content indicative of deficiency in luteinizing hormone. Recently, Taleisnik and McCann[3] reported a pituitary luteinizing hormone content in animals with persistent œstrus which was lower than in intact animals However, after gonadectomy the amount of luteinizing hormone of persistently œstrous rats showed an increase, but the level of hormone in plasma remained low, indicating that the pituitary release of the hormone is blocked On the other hand, Hillarp[4] concluded, also on the basis of the condition of the ovarian interstitial tissue, that during persistent œstrus luteinizing hormone was still being secreted in considerable amounts In other work, the possibility was stressed that in persistent œstrus induced by lesions, secretion of follicle stimulating hormone may be enhanced, because in animals which had been operated during the first two weeks after birth, puberty occurred at an earlier age than in control animals After puberty, a number of these animals showed persistent œstrus[5] A third possibility has been advanced by D'Angelo and Kravatz[6], who assumed that in persistently œstrous rats secretion of follicle-stimulating hormone may be decreased This assumption was based on their finding that the serum of unilaterally gonadectomized

rats with persistent œstrus contained less follicle-stimulating hormone than that of cycling animals after removal of one ovary.

There is no conclusive evidence for any of these hypotheses. Cook[7] was unable to detect differences between separate pituitary contents of follicle-stimulating and luteinizing hormone when the pooled glands of rats with persistent œstrus were compared with those of intact or operated rats with regular cycles.

We are investigating gonadotrophin contents in pituitary gland and serum of rats with persistent œstrus following a basal lesion in the anterior part of the hypothalamus; the lesions involved the dorsal and caudal end of the optic chiasm. This preliminary report concerns results on pituitary luteinizing hormone. Assays were carried out in the following manner. Individual pituitary glands were homogenized in saline solution with a Potter–Elvehjem apparatus, the final volume of each homogenate being 12 ml. Twice daily 0·5 ml. of each homogenate was injected beneath the skin into one hypophysectomized immature male rat (body-weight 30–40 gm.) for six days, resulting in a total dose of 0·5 equivalent of one single hypophysis. The weight of the ventral prostate served as an index of the luteinizing hormone potency of the pituitary homogenate. The control group consisted of twenty-five rats with a lesion which showed normal cycles, and twenty-three intact rats. Since no differences were apparent between the results obtained in these two categories they were combined in this work. Gans and De Jongh[8], using a slightly different method for assay of luteinizing hormone, have found that pituitary luteinizing hormone fluctuates during the œstrous cycle with a peak during late di-œstrus followed by a decline in pro-œstrus. In the present work, therefore, the data on control rats were related to the phase of the œstrous cycle prevailing at the time of death. The finding of Gans and De Jongh was confirmed as may be seen from Table 1. Animals with persistent œstrus possessed a high pituitary luteinizing hormone potency, comparable with that noted in the late di-œstrus phase of the normal cycle. Both the weights of the ventral prostate and of the testes of recipients of pituitary homogenates derived from these two groups of individuals were significantly higher than those of recipients of homogenates obtained from rats in œstrus or early di-œstrus.

These findings show that a hypothalamic lesion causing persistent œstrus and inhibition of ovulation does not necessarily block the production of luteinizing hormone within the pituitary gland. The high pituitary content may be the result of an enhanced production or an inhibited release of luteinizing hormone. It is of great interest that preliminary results on serum luteinizing hormone have brought to light a marked contrast between the conditions of persistent œstrus and late di-œstrus; while the high pituitary luteinizing hormone content of late di-œstrus has a parallel in the high serum content, the serum of rats with persistent œstrus possesses luteinizing hormone in only barely detectable amounts. If the latter finding can be confirmed, it would seem that a hypothalamic lesion which does not necessarily affect production of luteinizing hormone may inhibit its release from the gland.

Morphological Changes following Transplantation and Chronic Obstruction of the Rabbit Appendix

EXPERIMENTS reported by Sholpo[1] from the Moscow Medical Institute are claimed to be evidence in support of the theory that morphology and function depend on environment. In a series of 46 animal experiments Sholpo transplanted the rabbit cæcal appendix to various sites in the small bowel, almost all in the ileum. After three months the transplanted appendices showed marked reduction in the size of the lymphoid tissue. The results were summarized as follows:

"The vermiform appendix appears to be a convenient object for experimental researches on re-activity and plasticity of tissues of the digestive system. When surgically inserted into the digestive tube at different levels of the latter, the appendix finds itself in (an) unusual functional condition. The operation results in a substantial reconstruction of the wall of this organ: the glandular layer develops intensively, the lymphoid layer reduces both in thickness and in numbers of rows of lymph follicles. The appendix of (the) rabbit begins to display considerable muscular activity which is wanting under normal conditions".

It seemed to us unlikely that the changes which Sholpo described could occur as a result of an altera-

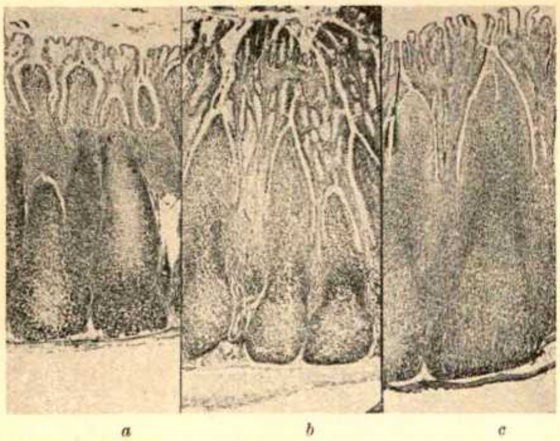

Fig. 1. The microscopical appearance of the wall of (*a*) the appendix; (*b*) the saccus rotundus and (*c*) an agminate patch. The villi of the glandular layer are on the top, the main thickness is formed by the lymphoid tissue and a thin muscular layer lies beneath

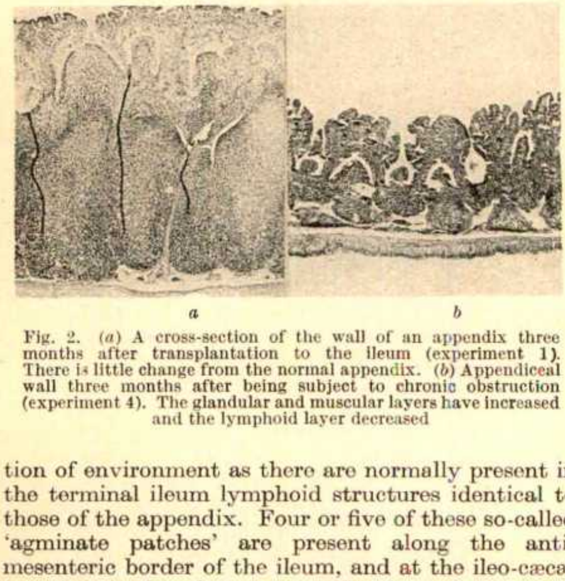

Fig. 2. (*a*) A cross-section of the wall of an appendix three months after transplantation to the ileum (experiment 1). There is little change from the normal appendix. (*b*) Appendiceal wall three months after being subject to chronic obstruction (experiment 4). The glandular and muscular layers have increased and the lymphoid layer decreased

tion of environment as there are normally present in the terminal ileum lymphoid structures identical to those of the appendix. Four or five of these so-called 'agminate patches' are present along the anti-mesenteric border of the ileum, and at the ileo-cæcal junction is found a large collection of lymphoid tissue, the saccus rotundus. The similarity of the microscopical structure of these lymphoid areas to that of the appendix is shown in Fig. 1. Their function also is similar[2]. We therefore felt that an environment compatible with the development of an agminate patch was unlikely to result in the structural alteration of the lymphoid tissue in the appendix, yet we too had observed changes similar to those found in Moscow in appendices transplanted into the ileum. However, as we became more practised at performing the anastomosis we found that these changes occurred less frequently, and stenosis at the suture line became less common.

Table 1

Operation	No. of rabbits	Died	Histologically normal after 3 months	Showing marked histological change after 3 months	With obvious anastomotic stenosis
1. Appendico-ileostomy	6	0	5	1	1
2. Appendiceal inter-position	6	0	3	3	2
3. Ileal diversion	6	3	3	0	0
4. Cæcal obstruction	6	0	0	6	—

Four experiments were therefore devised, the first three exactly like those of Sholpo and the fourth providing obstruction without transplantation: (1) The base of the appendix was separated from the cæcum and the tip anastomosed to the ileum. (2) The appendix was used as a replacement for an excised piece of ileum of equal length. (3) The ileal stream was diverted through the appendix into the cæcum by an end-to-end anastomosis. (In each operation the blood supply to the appendix was preserved and the anastomosis performed with 5/0 arterial silk sutures.) (4) In a further six rabbits the appendix was not disturbed but subjected to a chronic obstruction by producing a proximal cæcal stenosis with carbolized tape.

The normal histological appearance following three months transplantation is shown in Fig. 2*a*. After three months of chronic cæcal obstruction the glandular layer had developed, the lymphoid thickness reduced and the muscle thickness increased (Fig. 2*b*). In only one of the four transplanted appendices which showed a structural change was there no demonstrable suture line stenosis and here there appeared to be a functional obstruction as there was hypertrophy of the proximal ileum.

Sholpo's thesis is therefore rejected. The changes he described following appendiceal transplantation are, we suggest, the result of chronic obstruction as a result of the anastomosis and not the result of altered environment.

Increased Iron Absorption without Increase in the Rate of Erythropoiesis

IT is generally agreed that under normal conditions in man the total body iron is maintained at a relatively constant level by some mechanism which regulates the amount of iron absorbed from the gastro-intestinal tract. Apart from manipulating intra-luminal conditions within the intestine, numerous experimental conditions are known which increase iron absorption and which have in common an accelerated erythropoietic rate. These include anoxic hypoxia[1], cobalt administration[2], erythropoietin administration (Mendel, G. A., unpublished observations), pyridoxine deficiency[3], acetyl phenylhydrazine induced hæmolytic anæmia[4] and anæmia induced by loss of blood[5]. The rate of erythropoiesis has been considered of major importance under 'physiological' conditions in regulating iron absorption[6,7]. In certain disease states, such as hæmochromatosis, however, iron absorption may be increased without measurable increase in erythropoietic rate[8]. It is the purpose of this preliminary communication to report an experimental condition in which gastro-intestinal iron absorption is increased above normal in the virtual absence of erythropoiesis.

Erythropoiesis in the bone marrow of young adult *CF* No. 1 female mice was greatly reduced by the

Table 1 EFFECT OF HYPOXIA ON IRON ABSORPTION AND ERYTHROPOIESIS IN NORMAL AND SPLENECTOMIZED MICE TREATED WITH STRONTIUM-89

Treatment	Percentage of iron-59 absorbed from gastro-intestinal tract (72 hr)	Percentage of intravenous administered iron-59 incorporated into red blood cells (24 hr)	Average reticulocyte count at time of iron-59 administration (per cent)

* Standard error of mean

intraperitoneal administration of 4 μc /gm of strontium-89_{2+} chloride Jacobson[9] has shown that animals so treated rapidly develop compensatory ectopic erythropoiesis in the spleen For this reason splenectomy was performed on the day prior to the administration of strontium-89 Eleven days after injection of strontium-89, the rate of erythropoiesis as measured by the incorporation of 1 μc of intravenously administered ferric iron-59 citrate into red cells was reduced from the normal of 38 8 per cent to 4 1 per cent (Table 1) Reticulocyte values were correspondingly reduced The gastro-intestinal absorption of 1 5 μc of force-fed ferrous iron-59_{2+} sulphate was measured, as previously described[2], using total body counting in a Geiger–Muller well counter Iron absorption was somewhat reduced from the normal value of 15 5 per cent to 11 6 per cent in the splenectomized animal treated with strontium-89 It should be noted that in these experiments iron absorption was measured over a 3-day period to allow time for the elimination of unabsorbed radioiron from the gut The incorporation of intravenously administered iron into red cells was measured during the 24-hr period coinciding with time of maximum iron absorption[2]

The influence of hypoxic anoxia on the gastrointestinal absorption of iron-59 sulphate was studied in groups of normal and splenectomized mice injected with strontium-89 Hypoxia was produced by placing the animals in a chamber in which a gas mixture containing 10 per cent oxygen was maintained Twenty-four hours after being placed in the hypoxia chamber, intravenous or intra-gastric iron-59 was administered Twenty-four hours later, the animals were removed from the chamber Normal mice made hypoxic showed a marked increase in iron absorption (33 1 per cent) as well as an increase in erythropoietic rate (56 5 per cent) (Table 1) The splenectomized mice treated with strontium-89 that were made hypoxic likewise showed a marked increase in iron absorption (30 3 per cent) but no increase in the rate of erythropoiesis (4 0 per cent)

Mazur[10] has presented evidence that the transfer of iron from liver ferritin to the plasma under hypoxic conditions in rabbits, guinea pigs and dogs is mediated by the enzyme xanthine oxidase The present demonstration of increased iron absorption independent of increased utilization of iron by the bone marrow under hypoxic conditions suggests that a similar enzymatic mechanism may be of importance in the regulation of iron absorption The hypoxic splenectomized animal injected with strontium-89 should provide a useful model for the study of enhanced iron absorption that is independent of accelerated erythropoiesis The details of these experiments as well as related studies will be reported at length elsewhere.

PHARMACOLOGY

Hypertensive Effects of Bradykinin in Rats

BRADYKININ obtained from ox plasma[1] and synthetic bradykinin cause intense vasodilatation in many mammalian species Intravenous injections of bradykinin lower arterial blood pressure in anæsthetized animals. On a molar basis, bradykinin is only ten times less active than acetylcholine and as active as histamine[1] Two crude bradykinin-containing extracts from ox plasma—one prepared by us and the other kindly supplied by Prof Rocha e Silva—were shown to have the typical depressor action in normal rats, but frequently produced a striking hypertensive effect in rats nephrectomized 16–24 hr before These results are similar to those obtained with anephrotensin prepared from rat serum[2]

It seemed of interest to investigate whether pure bradykinin has the same hypertensive action in nephrectomized rats as the crude extract Forty-six male rats (180–200 gm) were nephrectomized under brief bromethol anæsthesia, 8–24 hr later they were again anæsthetized with allobarbitone and their blood pressure recorded from a carotid by a membrane manometer Twenty-four sham-operated animals were used as controls Synthetic bradykinin (Sandoz) supplied in sterilized ampoules, and a natural (89 per cent) purified product prepared by Dr Elliott were diluted with Tyrode solution and injected into a femoral vein Three ranges of dose were used (μgm / 100 gm body-weight) low (0 005–0 1), medium (0 15–0 5) and high (0 55–6 0) Angiotensin-amide (5-valyl) and anephrotensin were tested in the same animal Anephrotensin was obtained from the serum of dogs nephrectomized 48 hr before, 0 005–0 1 ml of the purified extract was given intravenously

In the intact rat with normal blood pressure (110–130 mm mercury) pure bradykinin, whether natural or synthetic, decreased arterial pressure Occasionally a small rise followed the hypotensive response In nephrectomized rats three different types of response were observed (*a*) a rise in blood pressure, (*b*) a rise in blood pressure preceded by a transient and slight drop, and (*c*) a weak depressor effect, which was usually less pronounced than the effect of the same dose in a normal rat

The type of response obtained depended both on the level of arterial pressure at which the injection was given and on the dose Out of a total of 61 injections of 'low' doses given to nephrectomized rats with an arterial blood pressure less than 100 mm (60–100 mm), 62 per cent purely hypertensive, 36 per cent diphasic and 8 per cent hypotensive responses were obtained. The incidence of hypertensive effects decreases when higher doses are used But when low and medium doses were injected into nephrectomized rats with blood pressures of 60 mm or less, a hypertensive effect was observed in all instances In nephrectomized rats with high arterial pressures (100–140 mm), a hypertensive effect of low doses of bradykinin was observed in 31 per cent and after medium doses in 17 per cent

When intact rats (in which bradykinin is uniformly hypotensive) were treated with a ganglion-blocking drug such as pentolinium, bradykinin produced a hypertensive effect in 76 per cent and a diphasic response in 24 per cent In rats with low blood pressure due to pentolinium, bradykinin had a hypertensive effect in all instances

These results in anæsthetized rats show that the hypotensive action of bradykinin is converted into a hypertensive one when basal pressure is lower than usual This was seen in nephrectomized animals investigated 8–24 hr after removal of the kidneys and in intact rats treated with pentolinium; a purely hypertensive action of bradykinin is more frequently observed with small doses The hypertensive action of bradykinin seems to be more dependent on the initial level of the blood pressure than on the absence of the kidneys In contrast, dog anephrotensin produces stronger hypertensive effects in nephrectomized rats than in normal animals, irrespective of the initial blood pressure

The fact that low and medium doses of bradykinin in pentolinium-treated or nephrectomized rats cause hypertensive effects will have to be taken into account when such animals are used in tests for angiotensin in extracts of blood which contain bradykinin

We wish to thank the Gildemeister Foundation for financial aid for the work reported We are indebted to Dr Elliott, Dr Boissonnas (Sandoz, S A) and Dr Gaunt (Ciba, Ltd) for their generosity in supplying natural bradykinin, synthetic bradykinin and angiotensinamide (5-valyl)

Release of Noradrenaline from the Spleen of the Cat by Acetylcholine

Acetylcholine contracts the spleen of the dog[1] and cat[2]. In those species the effect of acetylcholine in contracting the spleen is not blocked by atropine, but is blocked by dibenzyline and reduced by prior treatment of the animal with reserpine, thus it appears that the action of acetylcholine may be mediated by releasing noradrenaline from its stores in the spleen, which afterwards causes a contraction The work reported here provides further evidence that acetylcholine liberates noradrenaline from the cat spleen

The cat spleen was prepared for the collection of samples of its venous blood by a method similar to that in ref 3, in which a large vein branching from the main splenic vein was cannulated In addition a branch of the splenic artery was cannulated to permit intra-arterial injections into the spleen Heparin was given intravenously The splenic nerves were divided to exclude the reflex liberation of noradrenaline Acetylcholine bromide (1 5 mgm) was diluted with the animal's own plasma immediately before use, and injected into the splenic artery Splenic venous blood was collected during the next 40-sec period by temporarily occluding the main splenic vein, so diverting the flow through the cannulated branch, the blood was centrifuged and the plasma stored at – 10° C until required for assay Control samples of plasma were collected before acetylcholine injections Plasma noradrenaline was assayed on the blood pressure of the pithed rat recorded with a strain-gauge transducer as described in ref 4 The acetylcholine in the plasma was assayed on the blood pressure of the cat, to see whether there was sufficient to interfere with the assay for noradrenaline It was found that the volume of plasma injected into the rat contained less than 2 μgm of acetylcholine As a further precaution against acetylcholine interfering with the noradrenaline assay the pithed rat was injected with 1 mgm of atropine and 1 mgm of hexamethonium This treatment blocked both the muscarinic and nicotinic effects of 1 mgm of acetylcholine

Table 1 Effect of Acetylcholine (1 5 mgm) injected into the Splenic Artery on the Noradrenaline Content (mgm /ml) of Venous Plasma from the Cat Spleen before and after Phenoxybenzamine (10 mgm /kgm)

	Before phenoxybenzamine			After phenoxybenzamine		
Cat No	Control	After acetylcholine	Increase	Control	After acetylcholine	Increase
1	30	30	0	30	50	20
2	60	100	40	80	170	90
3	50	50	0	50	75	25
4	7 5	10	2 5	10	20	10
5	15	15	0	15	25	10
6	30	30	0	35	70	35
7 (reserpine-treated)	10	8	−2	7 5	7 5	0
8 (reserpine-treated)	20	20	0	12	12	0

The results are summarized in Table 1 The injection of acetylcholine into the splenic artery produced contraction of the cat spleen, but only in two out of six experiments was this accompanied by a detectable increase in the noradrenaline content of the splenic venous plasma

Brown and Gillespie[3] found that phenoxybenzamine (dibenzyline) increased the amount of noradrenaline which appeared in the venous plasma after stimulating the splenic nerve, therefore phenoxybenzamine (10 mgm /kgm) was injected intravenously into the cats After phenoxybenzamine the injection of acetylcholine did not contract the spleen, but the amount of noradrenaline appearing in the venous plasma was increased in every experiment. This observation provides a parallel with the experiments of Brown and Gillespie[3], who found an increased output of noradrenaline into the splenic vein after splenic nerve stimulation in the presence of phenoxybenzamine They suggested that phenoxybenzamine prevented the access of noradrenaline to receptor sites so that more was detected in the venous blood However, phenoxybenzamine also has anticholinesterase activity[5] An anticholinesterase would increase the effect of injected acetylcholine in releasing noradrenaline, and the effect of nerve stimulation if acetylcholine were an intermediary in the release of noradrenaline produced by sympathetic nerve stimulation. Evidence for such an intermediary action of acetylcholine in the sympathetic nerves to the spleen has recently been obtained[2].

Two cats were pre-treated with reserpine as described in ref. 6 in order to deplete the spleen of noradrenaline. In these cats acetylcholine did not produce a contraction of the spleen, nor did it cause an increase in plasma noradrenaline either before or after phenoxybenzamine.

These experiments show that the intra-arterial injection of acetylcholine releases noradrenaline from the spleen of the cat. When the noradrenaline stores were depleted by reserpine the intra-arterial injection of acetylcholine failed to increase the noradrenaline content of the splenic vein blood. These observations provide evidence that the sympathomimetic effect of acetylcholine on the spleen is due to release of noradrenaline from stores within the spleen.

We thank Smith Kline and French (Australia) for a gift of phenoxybenzamine (dibenzyline).

Protection by Antioxidants against Lethal Doses of Carbon Tetrachloride

Rees, Spector and Sinha[1] have shown that 'Phenergan', 10-(2-dimethylamino-isopropyl) phenothiazine hydrochloride, protects against necrosis of liver cells in rats dosed with carbon tetrachloride. Afterwards, Gallagher and Rees[2] found that 'Phenergan' maintained normal concentrations of oxidized pyridine nucleotides in the liver despite the administration of carbon tetrachloride. These findings, together with those of McLean[3,4] and Gallagher, Gupta, Judah and Rees[5] that 'Phenergan' protects rats against liver necrosis due either to vitamin E deficiency or to administration of thioacetamide, suggested that 'Phenergan' operates on a general metabolic mechanism involved in the maintenance of cellular and mitochondrial integrity. The value of 'Phenergan' as an alternative to vitamin E indicated that its action might be associated with antioxidant properties. Therefore, the antioxidants[6,7] α-tocopherol, sodium selenite and *NN*¹-diphenyl-*p*-phenylenediamine were investigated as possible protective agents in carbon tetrachloride poisoning.

Female Wistar rats weighing 150–180 gm. were used. They were observed for 14 days after carbon tetrachloride had been administered.

(*a*) *Vitamin E*. Table 1 shows that 95 I.U. of α-tocopherol acetate administered intraperitoneally 40 hr. before 4 ml. of undiluted carbon tetrachloride/kgm. was given by stomach tube protected all of 15 rats against death. The death-rate was also reduced by administering 2 doses of 95 I.U. vitamin E at 24 and 6 hr. before carbon tetrachloride. Doses of 95 I.U. given with, and 5 hr. after, carbon tetrachloride were of negligible protective value. A smaller dose (19 I.U.) of α-tocopherol given daily for 3 days prior to administering carbon tetrachloride reduced the death-rate to 72 per cent of 18 rats as compared with 98 per cent of 43 rats given carbon tetrachloride only.

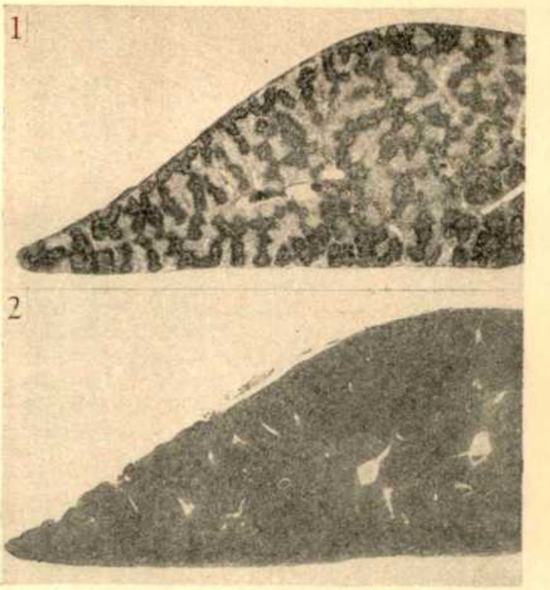

Fig. 1. Sections of liver stained with hæmatoxylin and eosin. (× 5). (1) Rat killed 24 hr. after receiving 4 ml. carbon tetrachloride/kgm. by stomach tube; the section shows widespread centrilobular necrosis and fatty change. (2) Rat killed 24 hr. after receiving 4 ml. carbon tetrachloride/kgm. by stomach tube. The animal had been given 100 mgm. DPPD in 0·3 ml. arachis oil intraperitoneally at 48, 24 and 0 hr. before carbon tetrachloride; the histology is almost normal

(*b*) *Sodium selenite*. Intraperitoneal injections of 0·5, 0·25, 0·25 and 0·25 mgm. sodium selenite at 72, 48, 24 and 6 hr. before the administration of 2·7 ml. carbon tetrachloride/kgm. reduced the death-rate to 51 per cent of 18 rats as compared with 89 per cent of 18 rats given this dose of carbon tetrachloride only (Table 2).

(*c*) *NN*¹-*diphenyl-p-phenylenediamine* (DPPD). Three intraperitoneal injections of 100 mgm. DPPD

		48	0·25			
		24	0·25			
		6	0·25	—	0	0

Table 3. Effect of NN^1-Diphenyl-p-phenylenediamine in the Prevention of Carbon Tetrachloride Poisoning

No. of rats	Treatment with DPPD: Time (hr. before carbon tetrachloride)	Treatment with DPPD: Dose (mgm.)	Carbon tetrachloride (ml./kgm.)	Deaths: No.	Deaths: Per cent
32	—	—	4·0	32	100
19	48, 24, 0	100	4·0	0	0
11	48	100	4·0	6	55
17	0	100	4·0	10	59
12	48, 24, 0	50	4·0	8	67
11	48, 24, 0	10	4·0	7	64

in 0·4 ml. arachis oil at 48, 24 and 0 hr. before giving 4 ml. carbon tetrachloride/kgm. protected all of 19 rats against death (Table 3). One dose of 100 mgm. DPPD either 48 hr. before or with carbon tetrachloride reduced the death-rate to 55 and 59 per cent respectively of 11 and 17 rats, as compared with 100 per cent of 32 rats given carbon tetrachloride only. Courses of 3 injections of 50 or 10 mgm. DPPD during the 48 hr. prior to administering carbon tetrachloride also reduced the death-rate.

The photomicrographs illustrate the protective effect of DPPD against histologically observable damage to the liver by carbon tetrachloride. Fig. 1 shows a section of the liver of a rat killed 24 hr. after having received 4 ml. carbon tetrachloride/kgm. The liver is typical for rats with severe acute carbon tetrachloride poisoning, showing centrilobular necrosis and fatty change. This contrasts with the virtually normal appearance of the liver section in Fig. 2, which is typical for rats killed 24 hr. after the same dose of carbon tetrachloride but which have been given 3 intraperitoneal injections of 100 mgm. DPPD during the 48 hr. before administration of carbon tetrachloride.

It seems likely that the antioxidants protect rats against the lethal effects of large doses of carbon tetrachloride by acting on a general permeability mechanism, and thus prevent the loss of mitochondrial and cellular pyridine nucleotides which would otherwise result from the physical damage to the cell produced by carbon tetrachloride.

HÆMATOLOGY

Thromboplastic Activity of Red Cells

The problem concerning the relationship of the thromboplastic activity of red cells to that of platelets which Inglis and Halliday[1] have recently studied has, in part, been answered by the work of my associates and me.

It was repeatedly noted that in very mild hæmophilia the prothrombin consumption carried out by my original method was often normal when whole blood was clotted, but not when the platelet-rich plasma was clotted under otherwise identical conditions[2]. This observation led to an investigation of the clotting factor in red cells and its probable role in the generation of thromboplastin. It was found that the activity of hæmolysed erythrocytes (hæmolysate) is similar to that of platelets but quantitatively much greater[3,4]. It is significant that, when a concentrated extract of platelets is added to normal native platelet-poor plasma that has been in contact only with silicone-coated surfaces, the consumption of prothrombin is too small to be determined; whereas, when the plasma is first brought in contact with a glass surface or treated with a minute amount of thrombin, the addition of a platelet extract brings about good consumption of prothrombin[5]. In marked contrast, the addition of an extract of red cells results in a high consumption of prothrombin even when added to native plasma that has been exposed only to silicone-coated surfaces[6].

These findings suggest that platelets can enter the coagulation reaction only after a plasma factor has been activated. Because this activation can occur by exposure to glass, the agent has been designated 'contact factor'. It appears that a platelet constituent interacts with the activated contact factor and that the resultant product is either very similar to, or identical with, the clotting agent found in the red cell. The latter factor, which appears to be a phospholipid[7], does not require contact factor to enter into the clotting reaction. From recent work it appears that some of the clotting agent formed from the platelets during clotting is removed by the red cells[8].

Whether the clotting activity of the intact red cell, which is feeble, has physiological significance remains unanswered. The alternative view that the red cell may be constantly removing this potent agent, which perhaps is being produced continuously, also deserves recognition and consideration.

We freely acknowledge the priority of Prof. Quick in discovering and reporting the platelet-like thromboplastic activity of red-cell hæmolysate. No reference was made to his work, as it was our opinion that it would be well known to all workers in this field.

The activity reported by us is, however, manifested by non-hæmolysed cells. According to previous reports, non-hæmolysed red cells are capable of exerting only feeble platelet-like activity. Prof. Quick concurs with this. Our work, however, has shown that this is true only in regard to the initial stages of coagulation, but that after the formation of fibrin becomes evident red cells which are still intact develop much greater activity. We have not, as yet, investigated whether this is due to the envelope of the red cell being attacked by thrombin. The activity may be due to the same element in the red cell as is responsible for the platelet-like activity of red cell hæmolysate; but if so, this element can act while still attached to an intact cell, provided that its activity is released by coagulation initiated in some other way This activity is not manifested in the prothrombin consumption test described by Prof Quick because the clot is separated by centrifugation, which also effectively removes the red cells That centrifugation has this effect also demonstrates that the activity observed is not due to red cells which have been hæmolysed Some of our recent observations tend to show that, prior to the red cell developing this activity, it has a contrary inhibitory effect This is in agreement with findings reported by Prof Quick

P_1 Antigen in the Human Fœtus

It is well established that in the human fœtus and new-born the P_1 antigen is incompletely expressed[1,2] In the course of testing blood from 403 fœtuses between the ages of 12 and 28 weeks we have confirmed that the incidence of P_1 is below the adult-level, however, it was found to be considerably higher in young than in old fœtuses Moreover, in the early fœtuses the strength of the agglutination also tended to be greater

Table 1

Crown-rump length	P_1^+	P_1^-	Total	Percentage P_1^+
Less than 10 cm	50	36	86	58 14
More than 10 cm.	67	250	317	21 14
Adults (ref 3)	1,984	641	2,625	75 58

Taking a dividing line at 10 cm it can be seen from Table 1 that the distinction between these two groups of fœtuses is highly significant

IMMUNOLOGY

Selective Secretion of Circulating Antibodies in the Milk of the Rat

PASSIVE immunity is transmitted from mother to young in the rat, as in the mouse[1], partly before birth, but chiefly after birth by way of the milk and the gut of the suckling. Postnatal transmission continues until the twentieth day of age[2], when the capacity of the gut of the young rat to absorb antibody terminates although antibody continues to be secreted in the milk The lactating female rat was chosen for investigating the transmission of antibody from the circulation to the milk.

320						1	2		
160					1	10	6	2	2
80					4	13	2		
40			1	3	9	5			
20		1	4	10	1	1			
10		6	2	1					

Serum titre

Female rats were actively immunized within a day or two of the first littering with *Brucella abortus* Two injections, one of 0 5 and another of 0 75 ml of the World Health Organization standardized *Brucella abortus* agglutination concentrate, washed and resuspended in a five-fold dilution in saline, were given two days apart subcutaneously in the neck region Paired samples of blood and milk were collected daily, or on alternate days, and the serum and milk whey titrated in parallel. The same procedure was repeated at the termination of subsequent pregnancies of these same animals

Antibody appeared in the serum five days after the primary immunization and by the ninth day had attained titres of 1/160–1/640 Thereafter the titres declined gradually to 1/40–1/80 by the end of the first lactation and were at or near this level at the time of each subsequent immunization The secondary response was more variable the majority of animals had attained comparable serum titres of 1/160–1/320, while a few animals showed titres of 1/640–1/2.560, by the seventh day

The appearance of antibody in the milk was strikingly different after primary, as compared with subsequent, immunizations After primary immunization antibody appeared in the milk one or two days later than in the serum, and by the tenth day reached maximum titres equalling or exceeding those in the serum Thereafter these declined more rapidly than in the serum After secondary immunization the milk titres did not rise appreciably, as did the serum titres, and remained nearly constant throughout lactation, seldom equalling and never exceeding the serum titres This difference in the ratio of milk to serum titres is shown clearly by comparing the data in *A* with *B* in Table 1 Evidently the antibody formed in response to a primary immunization appears in the milk much more readily than the antibody formed afterwards

It has been known since the pioneer work of Ehrlich[1] on mice that circulating antibodies, whether actively or passively acquired, do appear in the milk If it were assumed that the antibody was derived exclusively from that in the circulation, as seems probable, then that which was produced in response to primary immunization was transmitted more readily than that synthesized later This interpretation involves a selective transmission to the milk of certain molecular types of antibody in preference to others The only alternative interpretation would require the assumption of local production and direct secretion into the milk of antibody in response to the primary subcutaneous injection of antigen in the neck region, for which there is no evidence.

Selective transmission of antibodies and of labelled globulin has been demonstrated repeatedly in recent years across the fœtal membranes and is known to occur in the guinea pig[3], rabbit[4], monkey[5] and man[6] It occurs across the neonatal gut-wall in the mouse[7], rat[8] and hedgehog[9], though it has not been observed in the ruminants, horse or pig It occurs also across the yolk-sac wall of the chick[10] Hitherto, so far as we are aware, it has been recognized only in transmission across the fœtal membranes and the neonatal gut, so that this is the first instance recognized in an adult and in a glandular secretion

It will be a matter of considerable interest to determine whether the relative rates of transmission of different antibodies from the circulation to the milk of the mother rat correspond to, or are independent of, those across the gut wall of the suckling rat, or whether these two membranes, across which the antibodies must pass in transit from the maternal to the neonatal circulation, exercise selection on a similar or dissimilar basis

I am much indebted to Prof F W Rogers Brambell for helpful advice and encouragement in this work and Mr W A Hemmings and Dr R. Halliday for their interest, and to Dr A W Stableforth and Mr W T Rowlands, of the Animal Health Division of the Ministry of Agriculture, Fisheries and Food for supplies of antigen

PATHOLOGY

5′-Adenylic Acid Deaminase in Dystrophic Mouse Muscle

THE discovery[1], in 1955, of a hereditary myopathy in a strain of mice has provided a useful subject for the investigation of muscular dystrophy Although the ultimate cause of the mouse disease may not be identical with the cause of any of the human muscular dystrophies, it is a reasonable assumption that many of the secondary changes will be similar A number of workers have reported quantitative enzyme changes in the dystrophic mouse muscle Some activities, for example, cathepsins[2] and glucose-6-phosphate dehydrogenase[3], show an increase, others, for example, lactic dehydrogenase[4] and phosphorylase[5], are decreased

5′-Adenylic acid deaminase, which converts adenosine-5′-phosphate into inosine-5′-phosphate (apparently irreversibly) is known to be present in much higher concentration in skeletal muscle than in any other tissue Its physiological function is, however, uncertain The experiments reported here show a sharp decrease in the activity of this enzyme in dystrophic mouse muscle

Four pairs of female mice, of the Bar Harbor strain, 3–5 months old, were used The animals of each pair were litter-mates, the 'normal' mice were heterozygous with respect to the recessive gene responsible for the disease Muscle from the hind limbs was chopped finely and homogenized for 3 min with about 5 volumes of ice-cold distilled water in a Potter–Elvehjem homogenizer rotating at high speed The homogenate was kept in ice for about 30 min , and diluted (usually 1 · 50) with distilled water Suitable volumes were shaken gently at 37° C for 10 min in a medium (total volume, 1 ml) containing citric acid–sodium citrate buffer, *p*H 6 7 (0 1 *M*) and 5′-adenylic acid (sodium salt) (5 μmoles) Perchloric acid (1 ml , 10 per cent) was then added, after centrifuging the sample, the ammonia content of the supernatant was measured with Nessler's reagent Homogenates produced no measurable ammonia from adenosine under the same conditions

The reference base was 'non-collagen N', determined by standing samples of the homogenate overnight at 30° C with 0 1 *N* sodium hydroxide; they were then centrifuged and total nitrogen of the clear supernatant determined by a micro-Kjeldahl procedure (Such 'non-collagen N' represented on the average about 90 per cent of the total nitrogen of the tissue)

The results are shown in Table 1 It may be seen that the mean activity of the muscle from the affected animals was only about one-third that of the normals The activities bore no relation, in either group, to the age of the mice

Mixtures of homogenates from normal and dystrophic muscle were also tested. The combined activities were equal to the sum of the activities when tested separately, thus making it unlikely that

Table 1 5′-ADENYLIC DEAMINASE ACTIVITY IN SKELETAL MUSCLE FROM DYSTROPHIC AND NORMAL MICE

Ammonia produced (μmoles/mgm of non-collagen nitrogen)

	Normal	Dystrophic
	192	51 6
	127	60 8
	217	64 8
	206	54 6
mean	186	57 9

Muscle homogenates were incubated with 5′-adenylic acid as described the low activity of the dystrophic muscle is due to an inhibitory factor

The pH-activity curves in citrate buffer for normal and dystrophic muscle were similar, with a peak at 6 7 The relative activity of the two was approximately the same in succinate buffer (pH 6 4) as in citrate buffer, although the measured activities were about 25 per cent lower

Identification of Antibody in β_2-Globulins of Mouse Serum and Ascitic Fluid

MICE given intraperitoneal injections of antigen–adjuvant mixture[1-3] produce large amounts of ascitic fluid which contains specific antibodies Inbred *AKR* mice injected intraperitoneally with isologous tumour cell fragments in modified Freund's adjuvant developed large amounts of peritoneal fluid which contained specific cytotoxic and neutralizing antibodies[2,4] These observations had immediate practical importance since immunological studies have been limited by the small amount of antiserum obtainable from each mouse Since little or no information on the biophysical properties of mouse ascitic fluid is available, an investigation was made of its electrophoretic and immunological characteristics

Female *AKR* mice were injected intraperitoneally with complete Freund's adjuvant, incomplete Freund's adjuvant from which *Mycobacterium butyricum* was omitted, or complete Freund's adjuvant containing isologous lymphoma cell fragments Female *CF*1 mice were injected with crystalline bovine serum albumin in complete Freund's adjuvant Complete Freund's adjuvant (85 parts Drakeol mineral oil, 15 parts 'Arlacel A', 1 mgm of *Mycobacterium butyricum*/ml) was modified so that the aqueous phase was due only to the water contained in the packed lymphoma cell fragments or crystalline bovine serum albumin Antigen–adjuvant mixtures with little or no aqueous phase were more effective in causing ascites formation than conventional water-in-oil emulsions Animals received three 0 25 ml injections one week apart Approximately 2 weeks after the last injection ascitic fluid was obtained by paracentesis and blood by cardiac puncture Serum and ascitic fluid were clarified by centrifugation Moving-boundary electrophoretic analyses were made in a Spinco model *H* instrument (barbital buffer pH 8 6, $\mu = 0{\cdot}1$) The component containing antibody was identified by the boundary disturbance test[5] In this procedure antigen is added to the buffer in the electrophoretic cell Combination of antigen with antibody in a specific component forms a precipitate which interrupts the light and produces a clear area in the electrophoretic pattern Ascitic fluid was fractionated by starch block electrophoresis (barbital buffer pH 8 6, μ = 0 075), and the fractions tested for precipitins by the interfacial ring test

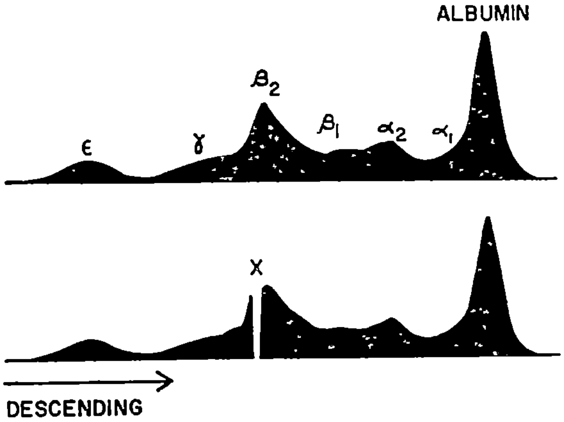

Fig 2 Electrophoretic boundary disturbance patterns of ascitic fluid from *CF*1 mice immunized with bovine serum albumin Top, control, bottom, 1 μgm bovine serum albumin/ml buffer

Normal *AKR* serum (Fig 1*A*) consisted of seven discernible components conventionally designated as γ-, β_2-, β_1-, α_2-, α_1-globulin, albumin, and a prealbumin component, ρ The concentration boundary is designated as ε Comparison of the electrophoretic patterns and analysis of the relative percentage of each component were made Serum pools and ascitic fluid pools from *AKR* mice injected with complete Freund's adjuvant (Figs 1*B*, 1*D*) or with complete Freund's adjuvant with lymphoma cell fragments (Figs 1*C*, 1*E*) had increased relative percentages of α_2- and β-globulins compared with normal serum The α_2-globulins were in greater concentration in the sera of immunized animals (Figs 1*B*, 1*C*) than in corresponding ascitic fluids (Figs 1*D*, 1*E*) The prealbumin component present in all serum pools was not detectable in ascitic fluid

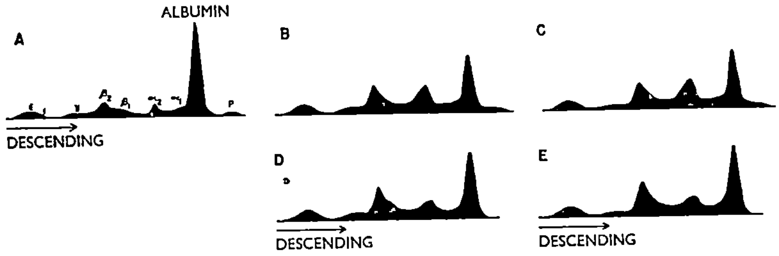

Fig 1 Electrophoretic patterns of *AKR* mouse sera and ascitic fluids *A*, Normal *AKR* mouse serum, *B*, serum from mice injected with complete Freund's adjuvant, *C*, serum from mice injected with lymphoma cell fragments in complete Freund's adjuvant *D*, ascitic fluid from mice injected with complete Freund's adjuvant, *E*, ascitic fluid from mice injected with lymphoma cell fragments in complete Freund's adjuvant

Animals injected with incomplete Freund's adjuvant did not produce ascites The *Mycobacterium butyricum* component of the adjuvant mixture was necessary for the induction of ascites by the immunization procedure described

Ascitic fluid from *CF*1 mice contained anti-bovine serum albumin precipitins A well-defined boundary disturbance (*X* in Fig 2) was produced in the β_2-globulin component when ascitic fluid (475 µgm. anti-bovine serum albumin protein/ml) was treated with 1 µgm of bovine serum albumin/ml. buffer Eluates obtained from starch-block electrophoresis of ascitic fluid contained anti-bovine serum albumin precipitins in fractions corresponding to β-globulins The *CF*1 serum was also shown to contain anti-bovine serum albumin precipitins in the β_2-globulin region by the boundary disturbance method

Serum and ascitic fluid from *AKR* mice had a similar distribution of electrophoretic components with one major difference Ascitic fluid did not contain prealbumin Relative concentrations of α_2- and β-globulins were greater in serum and ascitic fluid from immunized animals than in serum from normal mice, however, there was very little change in the relative concentration of γ-globulin This raised the question as to which component contained the antibody Boundary disturbance experiments showed that the anti-bovine serum albumin precipitins of mouse ascitic fluid and serum were contained in the β_2-globulin Prolonged immunization of the mouse might result in localization of antibody in a serum component other than β_2-globulin

Mouse serum contains a prealbumin component not detected in ascitic fluid The relative concentration of α_2- and β-globulins was greater in the serum and ascitic fluid of immunized animals than in the serum of normal mice, whereas γ-globulin remained relatively unchanged Anti-bovine serum albumin precipitins have been demonstrated in the serum and ascitic fluid of immunized mice and have the electrophoretic properties of a β_2-globulin

Nature of Increased Protein and DNA in Chronic Hepatic Injury

Excess protein and deoxyribonucleic acid (DNA) are found in chronic hepatic injury, for example, after administration of ethionine[1-3], butter yellow[4,5], 2 acetyl aminofluorene[6,7], and a high fat–low choline–low protein diet[1] This suggested that the excess protein or DNA is an abnormal product of the hepatocytes[1-3] This is supported by the incorporation of ethionine into hepatic proteins[2], presumably the abnormal proteins These proteins, or DNA, have been related to cancer[1,7] This communication is to point out that the excess protein formation results from alterations in cell population, rather than from formation of abnormal proteins

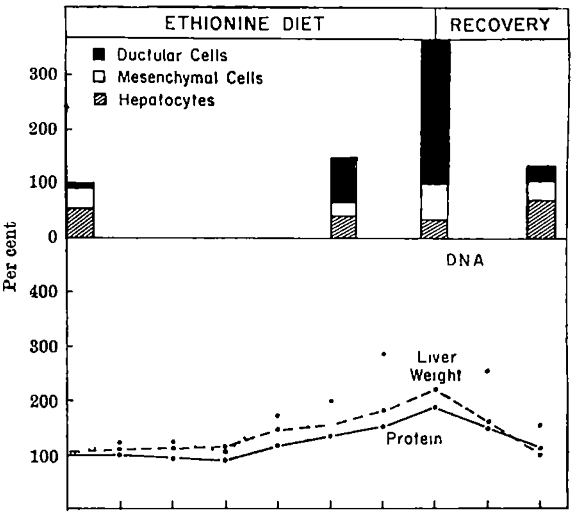

Fig 1 Changes in liver weight, hepatic protein and DNA content, and cell population during ethionine intoxication

A group of 42 rats was fed a synthetic diet supplemented by 0 5 per cent ethionine, with groups killed weekly up to seven weeks An additional 12 rats were similarly treated and then placed on the synthetic diet supplemented by 1 per cent methionine They were killed after one week or two weeks Twenty rats fed the synthetic diet alone were controls

From the third to seventh week the liver enlarged and its total protein content nearly doubled (Fig 1), with collagen (determined as hydroxyproline) accounting for only 5 per cent of the increment The total DNA content increased almost five-fold, while the RNA/DNA ratio decreased from 4 to 1 8 While in the control liver the ductular cells accounted (on the basis of differential cell counts) for only a small fraction of the population, with a ductular cell hepatocyte ratio of 1 10, after seven weeks on ethionine the ductular cells predominated, the above ratio being 7 1 Calculating the change in the total number of cells, the ductular cells increased about 50 times, while the number of hepatocytes decreased slightly (Fig 1) After two weeks of methionine supplementation, total protein and DNA reverted almost to control-levels, parallel with the disappearance of almost all ductular cells and a restoration of the cytological pattern of the liver After administration of 0 3 µc tritiated thymidine/gm body-weight at the seventh week of ethionine intoxication, incorporation of thymidine determined by scintillation counting was about 30 times the control (Table 1) Radioautographs demonstrated the label almost exclusively in ductular cells (Fig 2)

The rise in DNA is accounted for by the proliferation of bile ductules, qualitatively and quantitatively,

Table 1 Incorporation of Thymidine-^{3}H into Liver DNA, and the Distribution of Radioautographic Label in Different Cell Types in Control Rats and Rats Intoxicated with Ethionine

Diet	Total activity in DNA c /min	No of labelled cells per 100 high-power fields Hepatocytes	Mesenchymal cells	Ductules
Control	1,760	4	6	3
Ethionine (7 weeks)	47,250	12	18	200

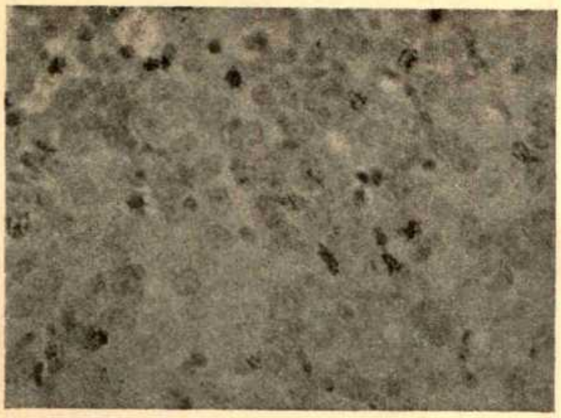

Fig. 2. Radioautograph of liver of rat fed ethionine for 7 weeks and then given tritiated thymidine. Labelled cells are all ductular cells. Hæmatoxylin. (× 120)

as shown by cell counts and autoradiography. Allometric analysis of the individual results for DNA and total protein shows a close relationship, indicating that the increase in liver weight and total protein are functions of proliferation of ductular cells. The smaller rate of increase in total protein and RNA than in DNA is explained by the much smaller cytoplasm to nucleus ratio of the ductular cell. In addition, the disappearance of excess protein and ductules during recovery run parallel. After a high-fat – low-protein diet, bile duct ligation and administration of α-naphthyl isothiocyanate and 2-acetyl aminofluorine, the same chemical and histological relationships hold true.

The excess protein and DNA are thus the structural protein of another cell type pre-existing in the normal liver rather than the accumulation of abnormal proteins as a reflexion of metabolic alterations of the hepatocytes. That the average cell size becomes smaller[5,6] is also explained by the proliferation of this new cell type. Radioautographs demonstrate that the previously observed increased uptake of thymidine-^{3}H (ref. 2) in ethionine intoxication is merely a reflexion of proliferation of ductular cells. No evidence exists that proliferation of ductular cells in the rat is related to carcinogenesis. The correlated approach applied emphasizes the value of morphological controls in the study of liver injury.

Translocated Heat Injury in Plants

TRANSLOCATED heat injury is common in burns of human beings[1] but is apparently not recorded in plants. When one of the two primary leaves of pinto bean (*Phaseolus vulgaris* L.) or cowpea (*Vigna sinensis* ((Torner) Savi) or the cotyledons of National Pickling cucumber (*Cucumis sativus* L.) was heated in water (5 sec. at 70° C. was suitable) and the opposite leaf abraded as in mechanical inoculation with viruses, the heated leaf was killed and the unheated leaf was severely injured. There was no apparent injury to the petioles and stem through which the injury stimulus passed. When the heated leaf was removed from the plant within 4 hr. after heating, the translocated injury to the opposite leaf was prevented, or recovery was favoured. Translocated injury still occurred if heating followed abrasion by as much as 12 hr., or if abrasion followed heating by as much as 16 hr., but comparable injury never occurred from abrasion or heat only. As the ratio of the area of the heated leaf to that of the unheated leaf was increased by removal of part of the leaf area, translocated injury was increased. The time of day to produce maximum translocated injury quickly was in the morning, but translocated injury could be produced at any time of day. Translocated injury was favoured by light and high temperatures in the environment. As the age of plants was increased from 12 to 23 days the degree of translocated injury was increased. The temperature coefficient for translocated heat injury was about 10. This translocated heat injury had various effects on infections which will be reported elsewhere. While no chemical responsible for translocated heat injury has been demonstrated, these results suggest a similarity between translocated heat injury in plants and animals.

A Distinction between Bolting and Flowering Effects on Senescence

IT is well known that flowering and fruiting processes bring about the senescence of most annual species of plants. Molisch[1] interpreted this senescence as due to the mobilization of food materials into the fruits. His interpretation has been questioned by Leopold, Kamien and Janick[2], for staminate as well as unpollinated pistillate plants of spinach show senescence after flowering. Both staminate and pistillate spinach plants develop a large seed stalk with the commencement of reproductive development, and it may be that Molisch's interpretation could be made more correct by including the mobilization of food materials into the stalk as an explanation of the imposition of senescence. The application of gibberellin to spinach which has not experienced photoperiodic induction will result in the formation of a stalk without the further development of flowers, providing an opportunity for distinguishing between the effects of bolting and of flowering on senescence.

Spinach plants of the 'Spica' variety planted on November 14, 1960, were grown under natural winter day-length. On March 31, 1961, twenty plants were selected for uniformity and divided into four groups of five plants each. Two groups were placed under short days (8 hr.) and two groups under long days (17·5 hr.). Day-lengths were shortened with curtains or lengthened with about 100 ft.-candles of tungsten light. Within each photoperiodic regime, one group was sprayed with 1,000 p.p.m. of gibberellic acid with the other group acting as a control.

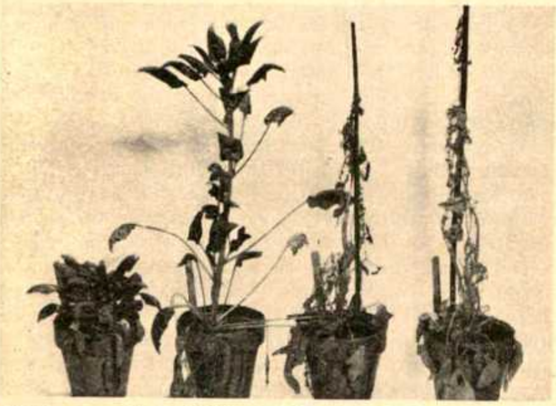

Fig. 1. Separation of bolting and flowering effects on senescence in spinach. Treatments from left to right: 1, short day; 2, short day + gibberellic acid; 3, long day; 4, long day + gibberellic acid. Photographed 49 days after treatment

Under conditions of long days, all plants bolted and flowered and afterwards showed senescence. The dates of death of plants treated with gibberellic acid and controls were essentially the same. Four of the ten plants were staminate and died in 33–51 days while the six pistillate plants died in 46–56 days. The final height of the plants treated with gibberellic acid was only slightly greater than the controls. Under the short-day treatment all plants were non-senescent at the end of 46 days, although the treated plants had elongated to an average height of 11 in. (Fig. 1). At this time two plants each from the gibberellic acid treatment and control were transferred from short- to long-day treatment. These flowered in two weeks and all showed normal senescence, the plants dying between 45 and 51 days from this date. Of the six remaining plants left under short days, four were abandoned as a result of insect infestation. The two remaining, one treated and one control, were non-senescent at the end of 74 days, a total of 120 days from the start of the original treatments, at which time the experiment was terminated.

The results demonstrate that the stimulation of an amount of stem growth in vegetative plants comparable with that produced in flowering spinach plants does not produce the stimulus for senescence which the bolting and flowering do. We suggest this as further evidence that the simple mobilization of materials is not the principal cause of senescence following reproduction, for the development of the small staminate inflorescences induces senescence whereas in contrast the growth of the massive central stem of plants treated with gibberellic acid had no detectable effect. For rapid growth of the stalk there must be a large mobilization of food substrates into the stalk and yet the death of the plant does not follow. It would appear that not all mobilizing forces within the plant induce senescence.

Biosynthesis of Gossypol by Excised Cotton Roots

GOSSYPOL, a toxic phenol, occurs primarily in the resin glands of cotton seed but also has been isolated from the tap-root bark of the cotton plant[1]. A study of the distribution of gossypol in the cotton plant revealed that the roots, especially the feeder roots, contained high levels of gossypol. This was true for strains of cotton in which the plants and seed were free of resin glands as well as for strains which contained many glands in plants and seed. The high levels of gossypol in the roots and the minute amounts in the seed of the glandless plants suggest that the gossypol was synthesized in the root tissue.

Since techniques for the growth of excised root tissue in sterile nutrient solutions have been developed[2,3] it seemed feasible to investigate the biosynthesis of gossypol by cotton root tissue. Excised root tips incubated in a sterile nutrient solution were used to determine if gossypol is synthesized by growing cotton root tissue. Dawson[4] found that excised roots of the tobacco plant synthesized nicotine.

The technique used for the culture of the excised root tissue was similar to that of Robbins with the tomato[3].

Cotton seed from both glanded and glandless strains were delinted with concentrated sulphuric acid and washed well with water saturated with calcium oxide. The seeds were sterilized by suspending them for 5 min. in a 0·5 per cent sodium hypochlorite solution ('Clorox' diluted 1 : 10). The treated seeds were washed three times with sterile distilled water and then transferred to sterile plates containing nutrient agar. The plates were incubated at about 30° C. until the roots had emerged from the seed to a length of 0·5–0·75 in.

The root tips were excised with a sterile razor blade and sampled randomly (Table 1, samples 1*a* and 2*a*) to determine the initial gossypol content. The remaining tips were transferred aseptically to 500-ml. Erlenmeyer flasks containing 150 ml. of sterile nutrient solution. The solution was identical, except for the inclusion of 0·05 p.p.m. of iodine, to that of Robbins[3], which contained the following in mμmoles per litre: thiamine 20, pyridoxine 200 and nicotinamide 200. The flasks were incubated for about 4 weeks. Some of the roots grew well, while others made little or no growth. At the end of the incubation period the roots were washed with water and, after separating the new growth (Table 1, 1*b* and 2*b*) from the original tips (Table 1, 1c and 2c) that were used to initiate the root culture, were dried. Both of these parts and the tips that were removed as control samples (Table 1, 1*a* and 2*a*) at the time of transfer into the nutrient solution were analysed separately for total gossypol content as I have already described[5].

Table 1. GOSSYPOL CONTENT OF EXCISED COTTON ROOTS GROWN IN NUTRIENT SOLUTIONS*

No.	Description	No. of cultures	Mean gossypol content (per cent)
	Glanded strain (1)		
1 *a*	Tips at time of transfer		0·080
1 *b*	New growth in nutrient solution	2	2·300
1 *c*	Incubated tips, new growth removed	2	6·320
	Glandless strains (2)		
2 *a*	Tips at time of transfer	2	0·051
2 *b*	New growth in nutrient solution	2	2·018
2 *c*	Incubated tips, new growth removed	2	1·361

* Values are expressed on an air-dried basis

The results of the analyses which are expressed on an air-dried basis are presented in Table 1. The concentration of the gossypol in the root tips (1*a* and 2*a*) at the time of transfer into the nutrient solution was low, although the level in the glanded strains was somewhat higher than that in the glandless strain. During incubation, however, the gossypol content of the original tips (1*c*, 2*c*) increased very markedly. This change was more apparent for the glanded strain, a 78-fold increase, than for the glandless strain. Moreover, the concentration of gossypol in the new root growth (1*b*, 2*b*) was many times higher than that observed in the original root tips at the time of transfer into the nutrient solution.

Thus these results clearly indicate that gossypol was synthesized by the excised root tissue. Furthermore a sample of root tips from the glandless strain that made no growth when incubated in the nutrient solution contained 2·315 per cent gossypol. This observation indicates that the root tips of the cotton plant have the enzyme systems for the production of gossypol even when they make no growth.

Juvenile Stage in Cultivated Forms of *Brassica oleracea*

Stokes and Verkerk[1] showed that while chilling induces flowering in Brussels sprouts, there was a juvenile stage during which chilling was ineffective. This is reflected in the horticultural practice of overwintering small seedlings derived from an August sowing of Brussels sprouts, which then grow vegetatively for a whole season without flowering. A similar procedure is successfully followed in the cultivation of spring and some autumn and cattle cabbage, suggesting the existence of a juvenile stage in these also, as if the plants, as a result of a too early sowing, are too large (that is, beyond the juvenile stage); winter chilling induces premature flowering (bolting) in the following spring[2,3]. I have, from August sowings, successfully overwintered outside, seedlings of autumn and winter cabbage (3 cultivars), kale (cottagers, hearting, marrow stem and thousand-headed), kohl rabi (4 cultivars), sprouting broccoli (2 white and 2 purple cultivars) and heading winter cauliflower or broccoli (9 cultivars), as well as those of spring cabbage. With all these cultivated forms a high proportion have, when transplanted to permanent quarters either in the October or April following sowing, continued to grow vegetatively, whereas plants from a July sowing all flowered in the spring following. This experience suggests that in all these cultivated types a juvenile stage exists during which chilling in ineffective in inducing flowering.

This feature was even more marked in plants raised from seed of a wild, although perhaps not indigenous, cabbage collected from the Yorkshire cliffs. Plants of this, from a sowing made on July 7, did not flower in the following spring, whereas all the plants from a corresponding sowing of the cultivated forms enumerated above did flower.

Kinetin-induced Meiotic-Prophase Acceleration and Stasis in *Tradescantia* Anthers cultured on Media Deficient in Sugar

THE ability of kinetin to accelerate mitotic division has been demonstrated for *Paramecium*[1], and an apparent effect of accelerating prophase has been inferred from onion root-tip work[2]. That the acceleration may be a direct consequence of a hormonal acceleration of discrete phases of cellular metabolism has been suggested[3,4]. The former workers found that synthesis of deoxyribonucleic acid (DNA) could be induced in tobacco pith tissue by kinetin; the latter found that it increased the activity of deoxyribonuclease and ribonuclease from bean hypocotyls. It is known that indole-3-acetic acid is also required for stimulation of division by kinetin and it has been shown that it is also required for the effect on nucleic acid metabolism[1-4]. In contrast with the stimulation of nuclear and cellular division, most workers have found that in higher concentrations kinetin causes abnormalities of division and eventually mitotic activity ceases.

We planned to determine whether acceleration could be detected in the prophase of meiosis in anthers of *Tradescantia paludosa*, in which the prophase stages investigated (from pachytene and diplotene onwards) are of sufficient duration to do so. The anthers were cultured on a modification of the basic medium used by Taylor[5] in which 4 per cent lactose was substituted for the equivalent of sucrose, to which kinetin at a concentration of 0·25 p.p.m. and/or different sugars were added. This medium provides semi-starvation conditions, in spite of which approximately two-thirds of the meiocytes in an anther proceed through both stages of the meiotic division with regular nuclear products when cultured at 27° C.

It was found that, among a group of fifteen anthers, excised at pachytene or very early diplotene, seven anthers treated with kinetin had advanced to diakinesis or beyond in 24 hr., and one was at late diplotene; six of the untreated anthers from the same buds were at early or mid-diplotene and one at diakinesis. In addition, in a test involving comparisons between the two lobes of an anther, one treated with kinetin, the other not, five of the treated lobes markedly outstripped the control, and only one showed apparent retardation. We conclude that kinetin accelerates prophase stages beyond pachytene. Since synthesis of DNA in the meiocytes of *Lilium longiflorum* is already completed before this stage[6] but synthesis of ribonucleic acid (RNA) reaches a peak during it, it is suggested that an enhancement of RNA synthesis, as indicated by observation of enhanced ribonuclease activity (ref. 4), may be responsible for this acceleration.

A large number of tests indicated that in anthers cultured for 48 hr. at mid-diplotene, kinetin caused a cessation of kinetic activity during the meiotic process that we have termed 'meiotic stasis' (Fig. 1). The observed pattern ('random stasis'), in which all the stages from diplotene to anaphase 2 have been detected, suggests that the phenomenon is caused by depletion of the cellular energy or substrate reserves, as a result of the accelerated development of prophase. Citrate, when added at a concentration of 83 p.p.m., markedly alleviated this nuclear stasis, and hence it appears probable that energy through the tricarboxylic acid cycle may be more critical than substrate.

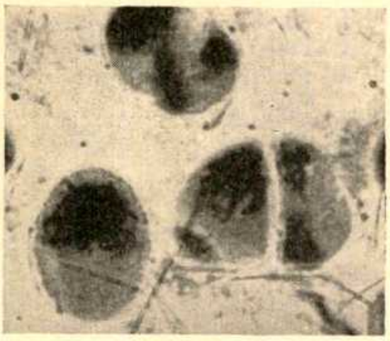

Fig. 1. Microsporocytes in stasis (see text) from a mid-diplotene anther cultured for 48 hr. sucrose-deficient medium containing kinetin (× 665)

In describing the inhibition of mitosis in onion root-tips induced by high concentrations of kinetin (1–5 p.p.m.) Guttman[2] mentions binucleate cells, massed prophases and small, dense cells with heavily stained nuclei. These observations coincide quite closely with our own observations of microsporocytes in kinetin-induced stasis. It appears probable that these abnormalities in mitosis also were a result of energy starvation brought about in the root-tips by nuclear acceleration induced by kinetin.

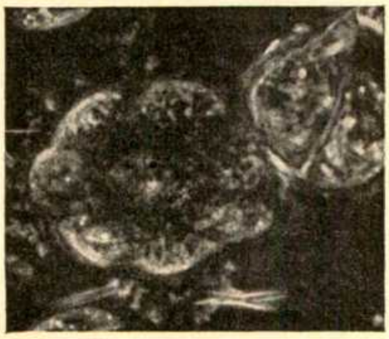

Fig. 2. 8-microspore 'tetrad' produced by an immediate division of the microspore nuclei, from a mid-diplotene anther cultured for 48 hr. on a sucrose-sufficient medium containing kinetin (× 665)

When citrate or sucrose was supplied, mid-diplotene meiocytes in kinetin-treated anthers frequently underwent three successive nuclear divisions within 48 hr. (Fig. 2). In contrast, under natural conditions on the plant, a period of 7 days elapses between the completion of the second meiotic division and the first mitotic division of the microspore[7]. Hence the action of kinetin in this instance apparently involves an elimination of almost the whole of the long intervening metabolic period in the microspores. This would suggest that it controls at least the conditions for the replication of DNA, since in *Tradescantia* microspores the replication occurs at the end of the interphase[8]. This evidence therefore supports that of Patan *et al.*[3] from mitotic work with tobacco pith tissue that the induction of DNA synthesis in the interphase nucleus is a significant feature of kinetin activity.

Plankton on the North Kenya Banks

During the investigations of the East African Marine Fisheries Research Organization into the resources of part of the coast of East Africa a hitherto uncharted shallow area was located off the north Kenya coast in the vicinity of Lamu[1]. Subsequent investigations have indicated that this area, designated the North Kenya Banks, has a good fish population and is of importance as a potential fishery[2,3].

Due to lack of specialists it has been difficult to make an extended and continuous investigation of the various facets of this marine environment which, together, result in the production of a good fishery. However, during plankton investigations along the East African coast, facts were discovered which substantiate the claim that the North Kenya Banks is a fertile area and potentially a good fishery.

Part of the plankton investigations constituted taking a series of lines of samples from the coast (c. 100 fm., or 50 fm. when the fringing reef permitted) outwards for some 40 or 50 miles. These lines of stations were worked from Cape Delgado, near the southern Tanganyika border, to Dick's Head, near the northern Kenya border; the outward lines from the coast were at approximately 30–50-mile intervals. The plankton net used was a Currie and Foxton 70-cm. net[4] without the meter. A filtration coefficient of 1 : 1 has been assumed (reasonable in the light of former experience), in view of the short duration of the haul, the speed of hauling (c. 1 m./sec.) and the evident lack of clogging. All were vertical samples from, usually, both 200 m. and 50 m. to the surface at each station. In shallower water the samples were from the bottom to the surface. All samples were duplicated, the first being for numerical and specific analysis, the second for dry weights. These latter samples were dried to a constant weight at 50° C. in a controlled oven. The resulting weights were applied to the height of the water column from which they were taken, the final result being expressed as mgm./m.^{3} of sea-water.

Full analysis of the results is not yet complete, but the preliminary results are of much interest. Towards Cape Delgado the plankton dry weight is about 8–12 mgm./m.^{3}, with no great variation in off-shore samples. Farther north in the Mafia area the coastal water is rather richer with *c.* 20–30 mgm./m.^{3}, decreasing to *c.* 8–12 mgm./m.^{3} in off-shore waters. This trend towards a relatively enriched coastal water increases to the north, and in the Dick's Head area in-shore figures are *c.* 30–40 mgm./m.^{3}, the off-shore figures being *c.* 10–15 mgm./m.^{3}.

A preliminary Survey Report of the 1960 cruise of the Russian research vessel *Vitiaz*, for the International Indian Ocean Expedition, shows the contouring of the plankton dry weight in the top-most 100 m. of the Indian Ocean. It agrees in showing that water with a low plankton dry weight (7·5 mgm./m.^{3}) is much nearer the coast-line in the Cape Delgado area than farther north in the Dick's Head area.

The stations worked over the North Kenya Banks showed the highest figures. Thus, among others, plankton dry weights of 65·1, 55·0 and 62·8 mgm./m.^{3} were recorded at the bottom end of the range, with the largest reading being 161·6 mgm./m.^{3}. This sample was taken at a depth of 108 m., the position being 2° 25·5′ S. 40° 54′ E.

These readings show that the water over the North Kenya Banks is demonstrably richer than the remainder of the Tanganyika–Kenya coast. Further readings will have to be taken before it can be stated confidently that this applies throughout the year, although there is reason to believe that this is, in fact, the case.

It is worth noting that the colour of the sea over these Banks was the 'bottle-green' associated with such temperate water as the North Sea, and neither the clear blue of the off-shore East African waters nor the dirtier blue or pale greens of the in-shore waters was in evidence.

Of interest is the consideration of the plankton dry weight underneath one acre of water over the North Kenya Banks. Assuming a mean depth of 80 m. and a plankton dry weight of 100 mgm./m.^{3} the resulting figure is 32·27 kgm. plankton dry weight beneath 1 acre of water.

Analysis of the preserved samples has not yet been completed, but random examinations give every indication of a richer population of fish eggs and larvæ compared with the rest of the coast. This poses the problem, to be investigated later, of whether the North Kenya Banks are a breeding ground, with the fish converging from outlying waters to breed, or whether the North Kenya Banks are mainly a feeding ground, the breeding being resultant and dependent on this.

CYTOLOGY

Increase in the Dense Cytoplasmic Bodies in Radiation-induced Giant Cells of the Cultured Fibroblast

The formation of giant cells after the irradiation of cell cultures was described by Puck and Marcus[1] in HeLa cells. The phenomenon also occurs in cultured fibroblasts. After a dose of 1,000 r., a high percentage of the cells in the cultures cease to undergo mitosis but continue to grow in bulk, forming characteristic giant cells which survive for about two weeks under normal culture conditions. Dickson, Paul and Davidson[2] have shown that the giant cells contain twice the deoxyribonucleic acid, ribonucleic acid, protein and lipid of the normal cell and that the synthesis of these compounds appears to be normal. The primary radiation effect, therefore, would seem to be on the mechanics of mitosis.

The non-irradiated, mouse subcutaneous fibroblast (strain *L* (ref. 3)) is roughly circular in thin sections under the electron microscope, with a single nucleus and cytoplasm containing typical mitochondria, sparse granular endoplasmic reticulum, a diffuse Golgi apparatus, numerous vesicles and 'dense cytoplasmic bodies'. The last-named are a characteristic feature of these and other cultured cells[4]. They are circular bodies, approximately 0·5 mμ in diameter, with a single outer membrane and opaque ground substance, and occur three or four to a cell in the thin sections. In a few cases the outer membrane is duplicated for part of its length, or even laminated. Rarely, a myeloid body is seen. Other structures are present, the ground substance of which is intermediate in density between that of the dense bodies and that of the cytoplasmic vesicles.

Pinocytosis can be demonstrated easily in these cells by growing them in a medium containing 2 per cent 'Thorotrast' ('Testagar'). After an hour, granules of thorium dioxide are present throughout the cytoplasm on the inner surface of membrane-bound vesicles. A few of the dense bodies also contain one or two granules at this stage. If cells treated with the 'Thorotrast' are returned to a normal medium for a further 24 hr., all the intracellular granules are segregated within the dense bodies which, therefore, correspond to the residual bodies of Palade[5].

In the giant cells developed from the fibroblasts after irradiation, the nucleus is large and convoluted so that thin sections often give an impression, seldom confirmed on light microscopy, of multi-nucleation. Individually the cytoplasmic structures are identical with those of the non-irradiated cells, though the Golgi apparatus may appear more diffuse. The striking feature of these cells, however, is the increase in the number of the dense bodies, which occur in groups of 12–15 in each cell in the thin sections. As in the normal cell, they are approximately 0·5 mμ in diameter, with a smooth outer membrane and opaque ground substance. Their internal structure is more variable, most have some lamellations and myeloid bodies are fairly common. After 'Thorotrast' treatment for 1 hr., the dense bodies of the giant cells, in contrast to those of the normal cells, show a considerable concentration of granules (Fig. 1). 'Thorotrast'-treated giant cells, returned to a normal medium for a further 24 hr. show the substance to be entirely localized in the dense bodies.

It is concluded that, as a result of continuous pinocytosis, when cell division in cultured fibroblasts

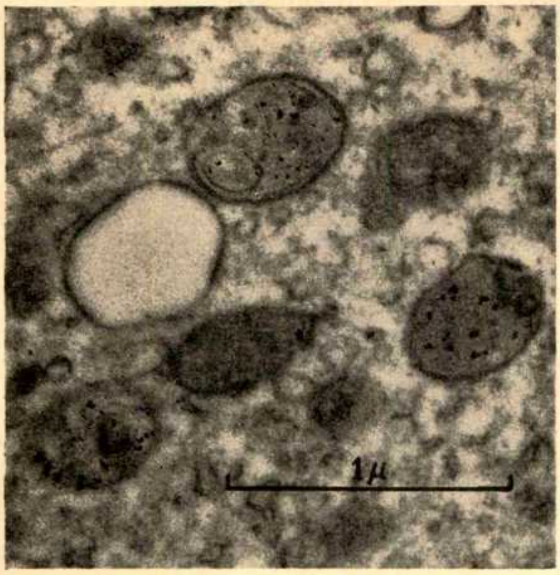

Fig. 1. Dense cytoplasmic bodies in an irradiation giant cell after 1 hr. in a medium containing 'Thorotrast'. The structures have internal membranes and contain granules of thorium dioxide

is prevented by radiation, the dense cytoplasmic bodies increase in number. The build-up of these structures, possibly with a high enzyme content, may be a factor in the death of these cells. The greater concentration of 'Thorotrast' in the dense bodies of the giant cells suggests that the rate of pinocytosis is greater than in the normal cells. Such a change could be correlated with the increased volume of the cell and the relatively decreased surface area available for the diffusion of nutrients.

I am grateful to Dr. J. Paul, of the HERT Tissue Culture Laboratory in the Department of Biochemistry, University of Glasgow, and to Miss M. Struthers, for technical assistance with the cultures.

MICROBIOLOGY

Incorporation of Molecular Oxygen during Microbial Utilization of Olefins

THE utilization of various alkanes by certain bacteria involves the incorporation of molecular oxygen into the conversion products[1] and into the bacterial cells[2]. The attack of the olefin 1-hexadecene at the saturated end of the molecule[3] probably is not different from that of the alkanes. Instances where the oxidative attack occurs at the double bond in olefins[3,4] have now been examined with the use of oxygen-18. Also, the cells of an ethylene-utilizing bacterium were analysed similarly.

The yeast *Candida lipolytica* A.T.C.C. 8661 was incubated at 30° C. for 4 days with continuous shaking in a closed 4-litre flask containing 800 ml. of the mineral salts solution of Bruyn[4], supplemented with 30 ml. of 1-hexadecene or 1-octadecene. The gas phase contained 80 per cent of labelled oxygen. The culture was extracted with diethyl ether. Chloroform was added to dissolve the diol crystals in the extracted unutilized olefin and the diols were purified by column chromatography[5]. The diols were recrystallized twice from *n*-hexane and dried *in vacuo* over phosphorus pentoxide (Table 1).

Table 1

	Hexadecane-1,2-diol	Octadecane-1,2-diol
Substrate	1-hexadecene	1-octadecene
Yield of recrystallized product	32·5 mgm.	70·6 mgm.
Melting point	85° C.	86·5° C.
Bromine test for double bond (ref. 6)	Negative	Negative
Periodate test for diol (ref. 7)	Positive	Positive
Purity, by periodate titration (ref. 8)	97·2 per cent	96·0 per cent
Analysis, found	C, 73·91 per cent; H, 12·75 per cent	75·12 per cent; H, 12·91 per cent
theory	C, 74·4 per cent; H, 13·2 per cent	75·4 per cent; H, 13·2 per cent
Formaldehyde produced by periodate oxidation (ref. 9)	Positive	Positive

The *Candida* cells from the octadecene culture were also analysed for oxygen-18. Cells of the 'ethylene bacterium' were recovered from mineral-salts medium in an atmosphere containing 10 per cent ethylene and 30 per cent of labelled oxygen. Cells of this bacterium were also obtained under comparable conditions with 1 per cent sodium acetate instead of the ethylene.

Isotopic composition of the products was determined by established procedures[10,11] (Table 2).

Table 2

Product	Substrate	Atom percentage excess ^{18}O		Percentage of oxygen in product derived from O
		O_2	Product	
Hexadecane-1,2-diol	1-Hexadecene	2·66	1·50	56·4
Octadecane-1,2-diol	1-Octadecene	5·47	1·69	31·0
Octadecane-1,2-diol	1-Octadecene	5·50	1·62	29·6*
Octadecane-1,2-diol	1-Octadecene	5·50	1·99	36·2*
Candida lipolytica cells	1-Octadecene	5·50	0·057	1·04
'Ethylene bacterium' cells	Ethylene	5·02	0·194	3·87*
'Ethylene bacterium' cells	Ethylene	5·02	0·164	3·27*
'Ethylene bacterium' cells	Ethylene	4·62	0·075	1·62
'Ethylene bacterium' cells	Sodium acetate	5·36	0·006	0·11

* Duplicate flasks in the same experiment. The orange-yellow pigmented ethylene bacterium was isolated from soil. It is a Gram-positive, aerobic, motile, non-sporulating rod. The minimal purity of the ethylene used in these experiments was 99 mole per cent.

Although a large fraction of the diol oxygen was derived from molecular oxygen, the results do not show whether one or both oxygen atoms of the diols came from the atmosphere. Assuming that the oxygen in any one position in the diol molecule was introduced by only one mechanism, the minimal theoretical value for incorporation is 50 per cent. The decidedly lower values for octadecane-1,2-diol in all probability indicate that an exchange had taken place whereby the oxygen-18 originally incorporated was partially replaced by oxygen-16 derived from water. The value of 56·4 per cent in the case of hexadecane-1,2-diol suggests that both oxygen atoms were derived initially from the atmosphere, but better evidence is required.

The cells of *Candida lipolytica* were also enriched in oxygen-18, as expected[2] from the assimilation of labelled intermediate diol. The 15- to 35-fold enrichment in oxygen-18 of the bacterial cells grown on ethylene over those grown on sodium acetate is indicative of an incorporation of molecular oxygen in the primary attack on the ethylene. By analogy, these results may be taken to imply, but not prove, that oxidation of ethylene by this bacterium takes place via ethylene glycol formed by the incorporation of molecular oxygen. Ethylene glycol was shown to serve as a sole source of carbon and energy for the 'ethylene bacterium'.

This work was supported in part by the U.S. National Science Foundation, the U.S. National Institutes of Health and the U.S. Office of Naval Research.

Antigenic Structure of *Entamœba histolytica*

IMMUNOLOGICAL investigations on the specific antigens of *Entamœba histolytica* are complicated by the presence of concomitant bacterial flora in the culture. The precipitin reaction in cases of clinical amœbiasis has been investigated[1,2]. Menendez[3] reported the presence of precipitin antibodies in the serum of rabbit immunized with cultures of *Entamœba histolytica*. In the present work the precipitating antigens of these parasites were analysed by agar-gel diffusion and intragel absorption techniques.

Entamœba histolytica, strain *E.H.* 1, was used in this work. The associated bacterial flora in the culture were *Escherichia coli* and *Pseudomonas pyocyaneus*. *Ent. histolytica* grown in Row's hæmoglobin media at 37° C. for 48 hr. was treated with dihydrostreptomycin sulphate to kill the bacteria. In each test, materials from thirty culture tubes were pooled and centrifuged at 2,000 r.p.m. for 5 min. The supernatant fluid was discarded and the deposit was re-suspended in Ringer's solution so as to contain about 100–150 parasites/low-power field. Sera of rabbits hyperimmunized with cultures of *Ent. histolytica* were used and are referred to as 'antiamœba' sera in this communication. Sera were also cultivated against *E. coli* and *Ps. pyocyaneus*.

Diffusion of antigen and antibody in agar gel was carried out according to the method of Feinberg[4] as adapted by Ghosh and Mukerjee[5]. In order to eliminate the reactions due to the antigens of associate bacteria, controls were set up with *E. coli* and *Ps. pyocyaneus* antigens in each test. It can be seen in Fig. 1*a* that 'antiamœba' serum gave rise to three precipitin bands against *E. coli* and two bands against *Ps. pyocyaneus* antigens. But when the amœba culture was used, a number of bands appeared between the antigen and antiserum wells and it was not possible to delineate the specific bands of amœbæ. This was due to the presence of antibodies against *E. coli* and *Ps. pyocyaneus* in the 'antiamœba' serum and the corresponding antigens in the antigenic preparations of amœba. By incorporation of 50 per cent (v/v) anti*coli* and anti*pyocyaneus* sera in the media, it was possible to absorb the bacterial antigens and identify the three specific precipitin bands of amœbæ.

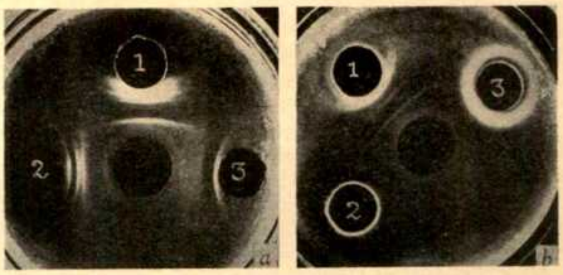

Fig. 1. *a*, Central well; antiamœba serum; 1, amœba antigen; 2, *E. coli* antigen; 3, *Ps. pyocyaneus* antigen. *b*, Intragel specific absorption 50 per cent anti*coli* and anti*pyocyaneus* sera (v/v) in gel. Arrangements of the wells are the same as in Fig. 1*a*. Note unmasking of three specific bands of amœba

On adding 'antiamœba' serum to the media all the bands, including those due to *Ent. histolytica*, were eliminated.

Since the rabbit's blood was used both for the preparation of Row's hæmoglobin media and as the source of antisera, no precipitin band appeared against media controls.

GENETICS

Skewed Recombination in a Rare Interspecific Jute Hybrid

Islam and Rashid[1] and Swaminathan *et al.*[2] have recently described the morphological and cytological characteristics of the F_1 hybrids between the two cultivated jute species, *Corchorus olitorius* L. and *C. capsularis* L. The F_1 plants studied were intermediate in phenotype, but an interesting genetic situation was found when we examined the F_2 and F_3 generations of two hybrids of *C. olitorius* (♀) × *C.*

capsularis (♂). Chromosome associations during microsporogenesis were analysed in the two F_1 hybrids, and five bivalents and one quadrivalent, or one trivalent and a univalent, occurred in several cells at diakinesis and metaphase I (ref. 2). One of the bivalents was heteromorphic. The F_2 progenies of these two hybrids contained more than 40 per cent of non-viable seedlings. Also, about 11 per cent of the F_2 population had various types of chlorophyll deficiency, abnormalities in leaf shape and poor vigour.

The varieties of *C. olitorius* and *C. capsularis* used in this work differed prominently from each other in branching habit, leaf index, flower size, number of stamens, size and shape of capsules, and seed colour. The F_2 population of one cross, comprising 138 individuals, was analysed for these characters according to the hybrid index procedure of Anderson[3]. The results (Fig. 1) show that there is a preponderance in the population of plants with an index value approaching that for *C. olitorius*. While a wide range of segregation was observed for the shape and size of capsule, no plant had the *capsularis* type of globose fruit.

Chromosome associations were studied in seven F_2 plants, and differential segments and inversion loops at pachytene, a heteromorphic bivalent at metaphase I, and a dicentric bridge and an acentric fragment at anaphase I were recorded. Two plants proved to be trisomics with $2n = 15$ and in both of them the capsules occurred in clusters of 5–7 as in the *capsularis* parent (Fig. 2), thereby indicating that the extra chromosome may be a *capsularis* one carrying the gene for this trait. In the F_3 population raised from one of the hybrids, phenotypic segregation was even more prominently skewed in the direction of *olitorius* than in the F_2.

The cytological results, the occurrence of a high proportion of unthrifty and non-viable seedlings and the skewed segregation behaviour observed in F_2 and F_3 progenies indicate that the genomes of *C. olitorius* and *C. capsularis* have differentiated in the direction of increased coherence[4], which automatically decreases the possibility for effective recombination. It has not been possible, so far, to make this cross with *C. capsularis* as the pistillate parent. Whether or not cytoplasmic factors have any role in determining coherence and the direction of skewness in segregation can be ascertained only when the reciprocal hybrid becomes available. From the point of view of breeding, the occurrence of trisomics in the hybrid progenies is a useful feature, since a way is thus open for substituting whole pairs of chromosomes that cohere but do not recombine.

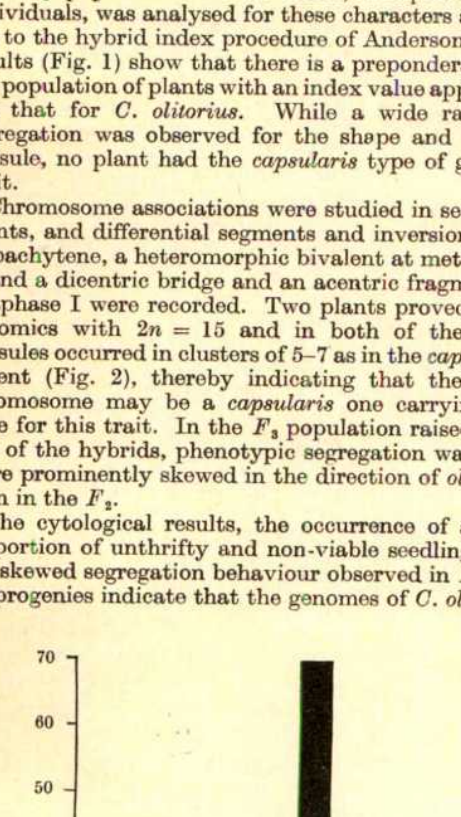

Fig. 1. Histogram showing the number of F_2 plants under each index value in the cross *C. olitorius* × *C. capsularis*. The population was scored for six different morphological characters and to each character typical of *C. olitorius* an index number of 1 was assigned. Thus plants totally like *C. capsularis* will have an index value of 0 and those like *C. olitorius* will have a value of 6. A value of 0·5 was given when the phenotype for a character was intermediate between that of the parents

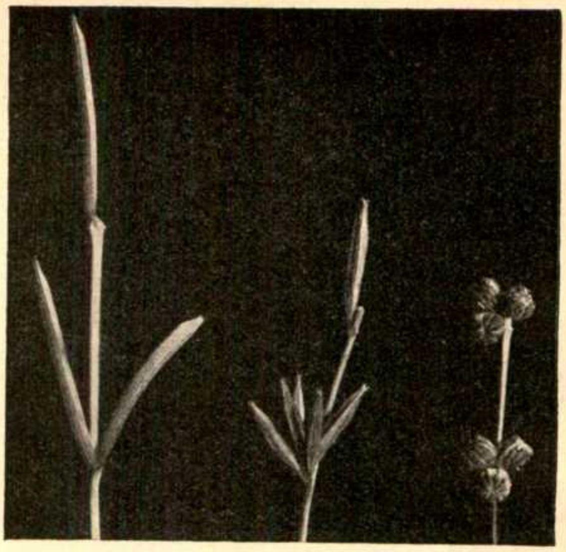

Fig. 2. Fruiting branches of (left to right), *C. olitorius* (♀), the trisomic F_2 with bunched capsules and *C. capsularis* (♂). 3/8 nat. size

Hæmoglobin Polymorphism in Fishes

MERISTIC and morphometric characters have been the most commonly used traits in the investigation of races or sub-populations of fishes. The differences in such characters among various populations may be due to variation in genetic as well as environmental factors. However, the relative influence of these two factors is usually unknown[1]. Consequently, it would be advantageous to use gene-frequency data based on Mendelian characters, the expression of which may be considered not to be influenced by environmental variation.

In mammals, especially man, this has been successfully done with blood types and hæmoglobin types[2,3]. Variation of blood-groups within fish species has been described by several authors[4–8]. Although zone electrophoresis of fish hæmoglobins has been reported by Buhler and Shanks[9] and by Chandrasekhar[10],

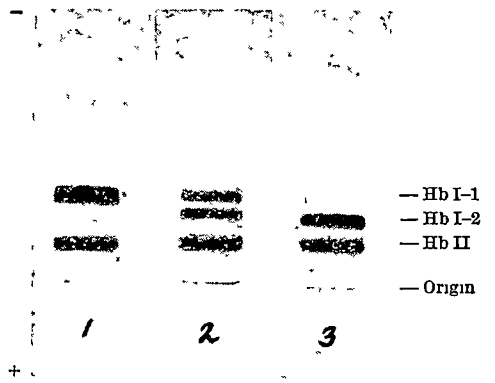

Fig. 1. Hæmoglobin patterns of whiting. 1, Type Hb I-1; 2, type Hb I-1-2; 3, type Hb I-2

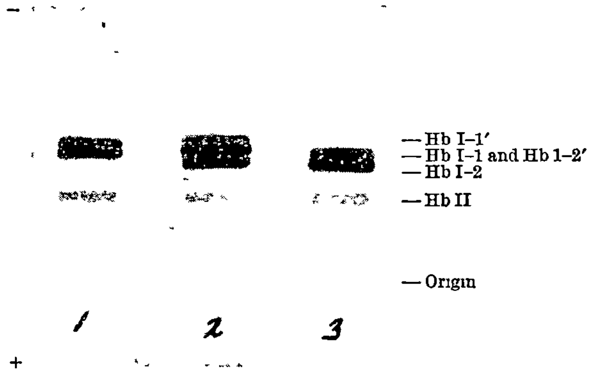

Fig. 2. Hæmoglobin patterns of cod. 1, Type Hb I-1; 2, type Hb I-1-2; 3, type Hb I-2

no intraspecific variation in electrophoretic mobilities was detected.

This communication describes hæmoglobin polymorphism in two species of fish, namely, whiting and cod. Polymorphism was detected by a modification of the agar electrophoresis technique described by Giri[11]. The present experiments were carried out with phosphate buffer (pH 7.3, ionic strength 0.02). Only freshly prepared oxyhæmoglobin solutions have been used.

In whiting (*Gadus merlangus*) three different electrophoretic patterns were found (Fig. 1). The whiting hæmoglobins were run at room temperature for 30 min. at 200 V. between electrodes. The patterns all have a slow-moving component (Hb II) in common. In addition, they may have either one or both of two faster-moving components (HbI-1 and HbI-2). The three types of individuals are called type Hb I-1, type Hb I-1-2, and type Hb I-2. Both in type Hb I-1 and in type Hb I-1-2 the Hb I-1 component is accompanied closely at the cathodic side by a weak minor component. No correlation of hæmoglobin type with sex or size of the specimen could be detected.

Apart from the common Hb II component the situation observed here is similar to the hæmoglobin polymorphism described in man, cattle and sheep. In these species, the underlying genetics have been elucidated[3]. By analogy a genetic hypothesis involving two alleles may be tentatively adopted to explain the genetics of the hæmoglobin variation observed in whiting. According to this hypothesis two co-dominant allelic genes Hb I^1 and Hb I^2 determine the hæmoglobin components Hb I-1 and Hb I-2 respectively. Type Hb I-1 and type Hb I-2 are considered as homozygous for the corresponding allele, and type Hb I-1-2 would represent the heterozygote. This hypothesis receives some support from the fact that the distribution of the supposed genotypes is consistent with the distribution calculated according to the Hardy–Weinberg law (Table 1). There is no significant heterogeneity between the samples represented in Table 1.

In cod (*Gadus morrhua*) three distinct patterns were again observed (Fig. 2). The hæmoglobin components of cod require longer time and cooling of the apparatus for their resolution. They were run for 60 min. at 200 V. between electrodes. It should be noted that although the same designations (Hb I-1, Hb I-2, and Hb II) have been used for cod and whiting hæmoglobin components, it is not known whether the two species have any component in common.

Both the Hb I-1 and the Hb I-2 component of cod hæmoglobin are accompanied at the cathodic side, by a minor component, Hb I-1′ and Hb I-2′ respectively. The Hb I-2′ component was inseparable from the Hb I-1 component in the supposed heterozygote as well as in an *in vitro* mixture of hæmoglobin from individuals of type Hb I-1 and Hb I-2. This situation is similar to that described for serum transferrin types in mice[12]. Since storing the cod hæmoglobin solutions tends to increase the relative amount of minor components, they may represent denaturation products.

A two-allele genetic hypothesis may also be adopted to explain the findings with cod. The results obtained are presented in Table 2. A highly significant difference in gene frequencies can be seen between the Bornholm sample and the three other samples. Apart from the Bornholm material the samples are consistent with the Hardy–Weinberg distribution and show similar gene frequencies. The poor fit ($P = 0.0004$) of the Bornholm sample is most easily explained by assuming that it represents a population homozygous or nearly homozygous for the Hb I^2 allele with some admixture of migrants from a population having gene frequencies similar to those

Table 1. DISTRIBUTION OF HÆMOGLOBIN TYPES IN SAMPLES OF WHITING FROM DIFFERENT AREAS

Type Supposed genotype	HbI-1 HbI^1/HbI^1	HbI-1-2 HbI^1/HbI^2	HbI-2 HbI^2/HbI^2	Total	Frequency of HbI^1 allele
Inner Danish Waters (Kattegat, The Sound, and Fehmarn Belt)	16	78	72	166	0.33
Southern North Sea (near Holland)	10	40	46	96	0.31
Northern North Sea (near Aberdeen)	10	21	21	52	0.39
Irish Sea	4	18	16	38	0.34

Baltic Sea, near Rønne, Bornholm	observed	2	2	74	78	0.04
	expected	0.1	5.8	72.1		

observed in the Sound and Fehmarn Belt This interpretation, although supported by results from Danish tagging experiments[13], should be tested by further investigation

In addition to cod and whiting, distinct intraspecific variation in hæmoglobin patterns has been observed in sole (*Solea solea*) and eel-pout (*Zoarces viviparus*) These preliminary results suggest that hæmoglobin polymorphism may be of rather common occurrence in fishes and that zone electrophoresis of hæmoglobins may become a valuable tool in taxonomic investigations of fishes at the sub-specific level

This work was supported by a grant from the Carlsberg Foundation Acknowledgment is due to Dr B. B Parrish, Marine Laboratory, Aberdeen, Scotland, to Dr M Roessingh, Rijksinstituut voor Visserij Onderzoek, Ijmuiden, Holland, and to Dr L Birkett, Fisheries Laboratory, Lowestoft, Suffolk, England, for providing samples of whiting blood

I am indebted to Dr O Frydenberg for suggesting this type of work to me and for helpful discussion and suggestions

VIROLOGY

Inactivation of Rous Virus by Phospholipase *A*

Rous virus is known to consist of protein, ribonucleic acid (RNA) and lipid, about 40 per cent of which is in the form of phospholipids[1,2] Partially purified preparations of the virus are inactivated by a wide range of lipid solvents—organic solvents, bile salts and synthetic detergents—and the loss of infectivity is associated with the shedding from the virus particles of protein-like material[3]

Anderson and Ada[4] have shown that Murray encephalitis virus—an arthropod-borne virus containing RNA, protein and lipid—is inactivated by phospholipase *A* This communication reports a similar loss of infectivity in Rous virus preparations incubated with phospholipase *A*

Partially purified Rous virus suspensions were made from fresh fowl-grown tumours according to the method of Carr and Harris[5] as modified by Bather[6]. Phospholipase *A*, supplied by Miss H Doery of the Commonwealth Serum Laboratories, had been purified from the venom of the black snake (*Pseudechis porphyriacus*) The concentration of enzyme used in these experiments was 100 μgm per ml of 0 9 per cent sodium chloride , each sample was boiled for 10 min to ensure that phospholipase *A* was the only functional enzyme present

Equal volumes of virus suspension (in phosphate-citric buffer *p*H 7 2) and phospholipase *A* were mixed and incubated at 37° C for 30 min As a control, the virus suspension was mixed in 0 9 per cent sodium chloride and kept at the same temperature and for the same time as the experimental tubes The infectivity of the control and treated samples was estimated by titration in young chicks[5]

Table 1 shows the loss of infectivity which resulted from the incubation of Rous virus with phospholipase *A* in two experiments Experiments with MH_2 tumour virus preparations have yielded similar results (Table 2)

Table 1 EFFECT ON INFECTIVITY OF ROUS VIRUS INCUBATED WITH PHOSPHOLIPASE *A* (100 μGM /ML) AT 37° C FOR 30 MIN

		Dilution of sample and No of tumours/No of chicks inoculated at each dilution							Infectivity
		10	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	10^{-6}	
1	Control	2/2	2/2	4/4	4/4	4/4	4/4	0/4	$10^{5\,5}$
	Treated	2/2	2/2	0/2	0/4	0/4	0/4	0/4	10^{1}
2	Control	2/2	2/2	2/2	4/4	4/4	4/4	4/4	$>10^{6}$
	Treated	2/2	1/2	0/2	0/4	0/4	0/4	0/4	10^{1}

Table 2 EFFECT ON INFECTIVITY OF MH_2 VIRUS INCUBATED WITH PHOSPHOLIPASE *A* (100 μGM /ML) AT 37° C FOR 30 MIN

		Dilution of sample and No of tumours/No of chicks inoculated at each dilution							Infectivity
		10	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	10^{-6}	
1	Control	1/2	2/2	2/2	4/4	4/4	1/4	0/4	$10^{4\,7}$
	Treated	0/2	0/2	0/2	0/4	0/4	0/4	0/4	0
2	Control	2/2	2/2	4/4	4/4	2/4	0/4	0/4	$10^{4\,0}$
	Treated	0/2	0/2	0/4	0/4	0/4	—	—	0

Since phospholipase *A* splits specifically only fatty acids bound in the – position, it was concluded from these results that Rous virus (and probably the other fowl tumour viruses as well) are inactivated by the cleavage of fatty acids from phospholipids contained in their structure

This result would support a previous suggestion[3] that the integrity of at least some of the protein bound to the phospholipid moiety in the extranucleoid region of Rous virus particles is essential for infectivity It may be that disruption of this phospholipid-protein wrapping is so radical as to cause irreversible injury to the virus RNA, and that it is this secondary effect which destroys the reproductive capacity of the virus On the other hand, the lipoprotein shell of Rous virus may allow the virus particles to react with some intracellular system and this 'acceptance' may be a necessary prerequisite for virus replication

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, December 4

Institute of Metal Finishing (in the Gower Room, Hotel Russell, London, W C 1), at 3 30 p m —Dr G L J Bailey "The Changing Face" (Presidential Address)

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 4 p m —Dr H E Huxley "Mechanism of Muscular Contraction" *

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place London, W C 2, at 5 30 p m Discussion on "Backward Waves in Waveguides", opened by Dr P J. B Clarricoats, Mr R A Waldron and Mr G H B Thompson

Institution of Mechanical Engineers, Applied Mechanics, Theory of Materials of Construction Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Can Plastic Components be Designed Rationally ?"

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 6 p m —Prof W K Estes (Indiana) "Current Foci of Research in Mathematical Behaviour Theory" * (Further lectures on December 7 and 11)

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Scientific Film Evening

Tuesday, December 5

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr H Kalmus "Biological Time-keeping" *

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m — Prof L F Bates, F R S "Domains and Domain Patterns"

Parliamentary and Scientific Committee, General Committee (in Committee Room 12, House of Commons, London, S W 1), at 5 30 p m —Dr D W Hill and Sir Charles Goodeve, F R S "The Developing and Financing of Research Associations"

Royal Society of Medicine, Pathology Section (at 1 Wimpole Street, London, W 1), at 5 30 p m —Symposium "On Histochemistry and Cytochemistry" Speakers Dr N. M Hancox, Mr S J Holt and Mr A J Hale

University of London (at Imperial College of Science and Technology, London, S W 7), at 5 30 p m —Prof M G Fleming Inaugural Lecture

Institution of Polish Engineers in Great Britain, Group for Economic, Social and Management Studies (at 55 Princes Gate, Exhibition Road, London, S W 7), at 7 p m —Mr E A Cooper-Key "Management Training in the Armed Forces and in Industry"

Royal Photographic Society of Great Britain (at 16 Princes Gate, London, S W 7), at 7 p m —Dr R G W Ollerenshaw "Design for Projection a Study of Legibility" (Eleventh Renwick Memorial Lecture)

Science Forum (at Friends House, Euston Road, London, N W.1), at 7 30 p m —Dame Kathleen Lonsdale, F R S "Statistical Ethics"

Wednesday, December 6

Institute of Physics and Physical Society, Colour Group (at the Northampton College of Advanced Technology St John Street, London, E C 1), at 3 p m —Dr B H Crawford "Colour Matching and Visual Adaptation"

Institution of Agricultural Engineers (at Cromwell Hall, Earls Court, London), at 4 p m —Dr A H Willis "Agricultural Engineering Problems in Australia"

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1) at 5 p m —Prof C. R Rao "Efficient Estimates and Optimum Inference Procedures in Large Samples"

Institute of Biology (in the Lecture Theatre of the British Museum (Natural History), Cromwell Road, London, S W 7), at 5 15 p m —Dr J M Tanner "Human Growth in its Comparative and Evolutionary Aspects" (Second Darwin Lecture)

Institute of Petroleum (at 61 New Cavendish Street, London, W 1), at 5 30 p m —Dr J A Carruthers and Mr K J Marsh "Charge Relaxation in Hydrocarbon Liquids flowing through Conducting and Non-conducting Pipes", Mr K J Wigley and Dr J A Carruthers "The Estimation of Electrostatic Potentials, Fields, and Energies in a Rectangular Metal Tank containing Charged Fuel"

British Institution of Radio Engineers, Computer and Medical Electronics Groups (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Discussion on "Possible Uses of Computers in Medical Diagnosis" opened by Dr A D Booth

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London W C 2), at 6 p m —Discussion on "Teaching Protective Systems" opened by Mr G. Heywood

Wednesday, December 6—Friday, December 8

Royal Photographic Society of Great Britain, Scientific and Technical Group (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 9 30 a m daily—Symposium "Document Copying by Photography"

Thursday, December 7

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Sir Gavin De Beer, F R S "The Origins of Darwin's Ideas on Evolution and Natural Selection" (The Wilkins Lecture)

Institute of Refrigeration (at the Institute of Marine Enginineers, The Memorial Building, 76 Mark Lane, London, E C 3), at 5 30 p m —Dr J C Fidler "Developments in Storage of Fruits"

Institution of Electrical Engineers (at Savoy Place, London W C 2), at 5 30 p m —Prof M W Thring "Magnetohydrodynamics" (Parsons Memorial Lecture)

Royal Institution, Library Circle (at 21 Albemarle Street, London, W 1), at 5 30 p m —Mr K D Vernon "Forgotten Worthies of the Royal Institution 2 William Savage and Thomas Webster"

Royal Meteorological Society (in the Conference Hall, County Hall, London, S E 1), at 5 30 p m —Mr C E Wallington "Meteorology and Gliding"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr F Kingsley Sanders "Infective Nucleic Acids and Virus Synthesis" * (Sixteenth of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

Oil and Colour Chemists' Association, *London Section* (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr A Macmaster "Aircraft Paints"

Royal Institute of Chemistry, London Section (at the Northampton College of Advanced Technology, St John's Street, London, E C 1), at 7 p m —Mr T M Dunn "Ultra-violet Spectroscopy"

Thursday, December 7—Friday, December 8

Powder Metallurgy Joint Group of the Iron and Steel Institute and the Institute of Metals (at Church House, Great Smith Street, London, S W 1), at 2 30 p m on Thursday and 10 a m on Friday—Winter Meeting

Friday, December 8

Association of Applied Biologists (at the British Museum (Natural History), South Kensington, London, S W 7), at 10 50 a m — Paper reading meeting

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W C 2), at 6 p m — Discussion on "The Peltier, Hall and Seebeck Effects"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Dame Kathleen Lonsdale, F R S "Restless Atoms in Solids"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Demonstrator (with a degree with biochemistry as a major subject and preferably some teaching or postgraduate experience) in Biochemistry at the University of Melbourne, Australia —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 15)

Lecturer (with an honours degree with special interest in inorganic and/or physical chemistry, and preferably experience in university teaching) in Chemistry at the University College of Townsville, University of Queensland—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (December 16)

Experimental Officer or Senior Experimental Officer (with Higher National Certificate, degree or similar qualification) in the Department of Electrical Engineering—The Registrar, The University, Manchester 13 (December 18)

Organic Chemist or Biochemist (with a good honours degree or equivalent qualification), for research in structural carbohydrate chemistry and immunochemistry—The Secretary, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S W 1 (December 30)

Lecturer in Geography, a Lecturer in Physics, and a Lecturer in Psychology at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

Lecturer (medical graduate of at least two years standing with experience in teaching and research) in Anatomy—The Secretary, The Medical College of St Bartholomew's Hospital, West Smithfield London, E C 1 (December 31)

Official Fellows (2) in Physics, to carry responsibility for the teaching of theoretical and experimental physics—The Warden, Wadham College, Oxford (December 31)

Assistant in the Sub-Department of Pharmacology, University College of The West Indies, for duties which include research, demonstration and some teaching for M B , B S , degrees of London University—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W C 1 (January 1)

Lecturers or Assistant Lecturers (2) (with a major interest in the theory of machines, and preferably an interest in metallurgy, machine design or engineering drawing) in Mechanical Engineering at the University College of The West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 1)

Lecturer or Assistant (preferably with a special interest in solid state physics) in Physics—The Secretary, Queen's College (University of St Andrews), Dundee (January 8)

Technicians (2) in the Department of Anatomy, Makerere University College, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 10)

Chair of Anatomy in the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 15)

Chairs (4) in Engineering in Monash University, Melbourne—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall London, S W 1, or The Registrar, Monash University, P O Box 92, Clayton, Victoria, Australia (Australia and London, January 31)

Senior Lecturer (with an appropriate science qualification and wide experience of clinical biochemistry) in Clinical Biochemistry at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, January 31)

Official Fellow and Tutor in Physics, or a Lecturer in Physics—The Principal, St Hugh's College, Oxford (February 1)

Imperial Chemical Industries Research Fellows in Chemistry, Physics, Metallurgy, Engineering, Geology, Agricultural Science or related subjects—The Registrar, University of Wales, University Registry, Cathays Park, Cardiff (March 5)

Assistant (graduate in astronomy, or in physics or electrical engineering (electronics) with some training or interest in astronomy) to the Director of the Jeremiah Horrocks and Wilfred Hall Observatories—Chief Education Officer, Municipal Building, Preston

Assistant Professor (with a Ph D in pharmacology), and an Assistant Professor (with a Ph D in pharmacognosy or plant chemistry)—Prof J R Murray, Director of the School of Pharmacy, University of Manitoba, Winnipeg, Canada

Biochemist for fundamental research on collagen and gelatin—The Director of Research, British Gelatine and Glue Research Association, 2*a* Dalmeny Avenue, Holloway, London, N 7

Chief Laboratory Technician—Head, Applied Physics Department, Northampton College of Advanced Technology, St John Street, London E C 1

Lecturers, Assistant Professors, and Associate Professors in the Department of Mathematics (Edmonton campus or Calgary campus)—Prof M Wyman, Mathematics Department, University of Alberta, Edmonton, Alberta, Canada

Lecturers (with a first- or second-class honours degree in mathematics, physics and most branches of engineering), to teach students for the B Sc degrees of London University—The Registrar, Royal Military College of Science, Shrivenham, near Swindon, Wilts

Librarian (with a knowledge of chemistry or physics) in the Department of Chemical Engineering and Chemical Technology—Head of the Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S W 7

National Coal Board Research Assistant (good honours graduate or equivalent) in the Department of Pure and Applied Chemistry, to continue a study on the origin of coal tar components—The Reader in Industrial Chemistry, Northampton College of Advanced Technology, St John Street, London E C 1

Research Assistant (with a good honours degree, or its equivalent, in physiology, biochemistry or zoology, and preferably experience in some field of hormone research or immunochemistry) in the Physiology Department, to study the physiology of prolactin with special reference to its assay in body fluids—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref 61/31

Research Assistant (with experience of numerical analysis and the writing of computer programmes) in the Mathematics Department—The Registrar, Brunel College of Technology, Woodlands Avenue, Acton, London, W 3

Senior Laboratory Technician in the Bacteriology Department, Connaught Hospital, Walthamstow, London, E 17—The Secretary, Forest Group H M C, Langthorne Road, Leytonstone, London, E 11

Senior Lecturer in Physics, and a Lecturer in Physics—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N 7

Senior Research Assistant (preferably with some research experience) in the Department of Physics, for a programme of work on the magnetic properties of thin films, provisionally for one year in the first instance—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey

Technician or Junior Technical Officer (female, preferably with "A" level G C E or equivalent), to assist in biological research at Pollards Wood Research Station, Chalfont St Giles, Bucks—The Secretary, Institute of Cancer Research, 33 Sumner Place, London, S W 7, quoting Ref 301/B/83

EXCELLENCE AND LEADERSHIP IN A DEMOCRACY

THE need to foster outstanding qualities among democratic peoples has formed the theme of a series of articles in *Daedalus* A number of draft papers were prepared and considered at a closed conference held at Middletown, Connecticut, during April 28–30 The final papers have now been brought together and published in the *Proceedings of the American Academy of Arts and Science* (90, No 4, Autumn 1961) Among the papers is one by Robert S Morrison, director of medical and natural sciences at the Rockefeller Foundation, who discusses the need for new types of excellence

Morrison began his inquiry by means of an informal survey among a representative group of friends Almost all found time to formulate thoughtful analyses of future needs This fact serves to document an awareness among intellectual leaders for something different and a good deal better than now exists All seemed well satisfied with the progress being made in expanding knowledge of the physical world and in applying that knowledge to the reduction of poverty and suffering Most of present pre-occupation is with organization, interdisciplinary co-operation, decision making, and value problems Science is increasingly confronted with large problems the parts of which are so interdependent that they cannot be dissected without spoiling them for future study A contribution by Warren Weaver shows how the scientific problems of the future merge without perceptible transition into the classical problems of the humane arts

"I have a very strong conviction", he wrote, "that the 'new forms of excellence' required by science over the next half-century will in considerable part consist of techniques for dealing with broader problems, larger problems, problems which arise when a moderate number of small problems are organically interrelated "

One can start with the very obvious and over-simplified examples "The day is past", Dr Weaver claims, "when science can properly treat food supply as an isolated problem, birth-rates as another, public health as another The whole body of servo-mechanism and feedback theory, many of the techniques of operations research, the emerging knowledge concerning information and communication theory—these are all groping toward the capacity to deal with problems of organized complexity

"We have been good at producing bits of information, fragments of knowledge We now need to devote more attention to the fitting together of these bits, to broaden interrelations, and hence to broader utilization We have to humanize science, and give more general meaning and structure—and even value—to it "

Most of the other correspondents to Dr Morrison's inquiry came directly to the need for synthesizing, interdisciplinary research, better organization, and better decision-making, without bothering to analyse how All recognize that it is the extraordinary dimensions of this pile which shape the demand for new forms of excellence

It is science which has (1) given so much information that no man can master more than a small portion of it, (2) given reality to the concept of one world, (3) given the populations of some parts of that world so many material possessions and so much power over their own destinies that for the first time the paramount question is not "How do I get enough to stay alive?" but "What do we do with a life that is more or less guaranteed?"

Each gift calls for its own sort of expertize, and, taken together, requires a form of human activity so new that there is no word to describe it The rapid accumulation of raw information and digested knowledge places unprecedented burdens on the minds and characters of those who follow the learned professions It is not cheering to know that this year's class of new medical students are confronted with four times as much to learn as their teachers encountered a short twenty years ago By the time these young men finish their courses they should return immediately to the basic sciences they studied as freshmen There will be as much that is new to them as there was when they studied the basic sciences the first time

It is not only the possession of specialized bits of knowledge that sets a specialist off from his fellows but also his different way of looking at things, and this may erect even more serious barriers Whole schemes of thought and discourse have developed to deal appropriately with the findings provided by separate skills, until ultimately the specialities are divided from one another not only by the possession of special information and manipulative skills but also by wholly different ways of thinking and talking Nowhere is this more clear than in the field of psychology Here there are psychoanalysts, learned theorists, conditioned-reflex addicts, physiological psychologists and ethologists, all looking at the same set of phenomena in such wholly different ways that they can scarcely hold sensible conversations with one another

The unsatisfactory nature of this state of affairs is widely recognized and lies behind the persistent cries for more 'interdisciplinary' research and better 'generalists' How does one set about becoming excellent in a general way ? If there is substance to the view that specialization arises from the invention of special methods of observation and is perpetuated by human incapacity to store and recall more than a small fraction of our exponentially increasing pile of data, it seems reasonable to give primary attention to simplifying these functions or transferring them to other hands Our best minds might then become freer to deal with conceptual and communication problems which worry us so much

There seems reason to hope that many of the basic scientific specialities are less separated by technique than they used to be The electron microscope was invented by physicists, but methods for its use have been worked out by chemists, cytologists, histologists, microbiologists, and an occasional physiologist It is beginning to give a view of biological work which is clearly more unified than anything before Now that instruments exist for analysing events at what is essentially molecular level, the attention of all specialities is beginning to focus at the same point As a result, the histologists, biochemists and physiologists are now holding livelier conversations with one another than at any time It is increasingly difficult to differentiate the basic science departments on the basis of the instrumentation used within them Basic biochemical apparatus, electron and light microscopes, cathode-ray oscillographs, and radiation counters may well be found in any of them Part of the increasing homogeneity is due to the recognition that all biological events can be traced to biochemical ones This means, in turn, that all biologists must learn to speak the *lingua franca* of biochemistry—and ultimately of atomic physicists, at least in so far as the nature of the chemical bond between atoms is concerned

The splitting of our scientific culture into language blocks does not doom man to the splendid isolation of the 'Tower of Babel' The separate ways, if pursued long enough, can lead to an even more splendid and imperial synthesis of crystal clarity. It is possible for a single individual to select and give a meaningful synthesis to the most significant facts and concepts of economics, sociology, history, business management, and political science—*vide* W W. Rostow, *The United States in the World Arena* As knowledge expands beyond a certain point, the burden on the individual can become less For it is much easier to grasp and to remember interrelated schemes in which a set of observations developed in one language can be interpreted in terms of another than it is to hold on to a mass of unrelated items

It also seems probable that the pursuit of excellence in the technology of gathering and processing data will help to free mankind from the burdens of specialization In the early stages of any natural science, the great advances come from devising new ways of observing Recent technical advances have reduced many of the essential manipulative skills to semi-automatic mechanical processes There is now, for example, a machine which will automatically analyse a complex protein for all its constituent amino-acids in a matter of hours Only a few years ago whole teams of skilled chemists were trying to find out how the job could be done at all

The second problem—how to handle the data after they are accumulated—is more difficult It remains for the future to devise an excellence which will make the most of the speed and accuracy with which mechanical computers handle large volumes of data, while at the same time maximizing the associative capacities and instinct for relevance contained within our own brains Enough progress has been made to suggest that computer techniques will be useful not only in storing and recalling existing information, that is, in improving the library function There are great possibilities for the development of machines which will analyse and correlate data as they occur For example, neurophysiologists and psychologists are now much interested in the possibility of correlating electrical events in the nervous system with functions such as perception, learning and memory

New forms of excellence are required for developing these new technologies for the accumulation and analysis of data More interesting, perhaps, is the challenge the new techniques offer for the development of even newer excellences It will not be easy to relinquish to the machine the arts and techniques which have taken decades to master, and to concentrate on the even more demanding tasks of generalization, synthesis and judgment which only men can carry out Perhaps the greatest demand for ingenuity will fall on the field of education, once it is decided to hand over to other means the mere memorization of information, the computing of sums, and such other routine intellectual tasks as may be found appropriate It will be an excellent teacher who shows how to programme school and college experience so as to maximize the capacity to grasp general principles, detect relevance where none was seen before, and create new conceptual schemes When that day comes, all education will be general education since the technical problems which now divide the specialities will in large part have been handed over to the computers, and "we will have taught ourselves a language we can all use in common"

Dr Morrison also examines the set of problems arising from the emergence of "one world" When radiation fall-out affects both the just and unjust of all peoples in the world, it is time to invoke Waddington's concept of 'stochastic' or 'statistical morality' which calls for a new kind of excellence that must be invented to deal with this new state of affairs The whole future of the race is at stake in such matters as the uncontrolled expansion of its numbers in the 'population explosion', or the decline in its quality brought about by the genetic effects of advances in modern medicine in combination with our present-day casual breeding patterns

There is a school of thought, particularly well exemplified by the tobacco industry, which attempts to shrug off the evidence for all such dangers as 'only statistical' At present the evidence available suggests that men who smoke a package or more of cigarettes a day are likely to die earlier than men who do not smoke at all Yet smoking habits have little changed The explanation seems to lie in the fact that men still find it very difficult to pay serious attention to contingencies that lie more than a few years in the future and are coupled to present events with a probability of less than one

After examining the need for improving standards of government, Dr Morrison shows how compulsive are the mass uses of indoctrination techniques. There is great need for responsible people to be constantly aware of the dangers inherent in specialities and in propaganda machinery. There is need for a combination of the highest sort of intellectual and moral attainments In the first place, it should be unnecessary in a democracy to point out that a speaker has no business to try to make the final decision for his hearers This would be, in fact, the simple way out and is common procedure in dictatorships, theocracies, and other controlled societies Democracy rests on the assumption that people in general will reach the right decision if they are given the truth But the truth is impossible to define in abstract terms, and even in concrete matters like the effect of radiation on genetic anomalies, is not much more than a fluctuating area of agreement

The telling of this kind of truth cannot be guaranteed by constitutional articles or perjury laws As more and more features of our life fall under the control of those who wield a specialized body of knowledge, control measures must be sought These can be found only in the individual moral and intellectual excellence of those who develop, hold, and disseminate knowledge

THE HISTORY OF SCIENCE

The Search for Order

The Development of the Major Ideas in the Physical Sciences from the Earliest Times to the Present. By Cecil J Schneer Pp xvii+398 (London English University Press, Ltd, 1960) 21*s*. net

THIS book belongs to the class, of which there have been several examples of late, of bird's-eye views of the history of physical science from early times to the present The chief defect of this type of work is that it inevitably omits everything but the direct ancestry of the science of our time, and makes what is in fact an almost indescribably devious course, constantly doubling back on itself, appear like a straight line Of its kind, however, it is among the best The story is told in a clear, straightforward and interesting manner, and, apart from an excessive number of small inaccuracies that could well have been avoided, the subjects dealt with are on the whole presented faithfully Those subjects include, mainly, physics, with some chemistry and a brief glance at geology and evolution. Despite a picture of a spiral nebula on the dust cover, there is no cosmology and next to no astronomy

There are a few surprising passages For example, the conflict between physicists and geologists over the age of Earth is presented as a conflict between "historical knowledge" and ordinary physical knowledge, as though these were different in kind, instead of as an instance of the different conclusions that can be drawn from two incomplete sets of data On a smaller scale, while it is certainly true that J. J. Thomson "lived on into the electronic era", the essence of the fact scarcely appears in that expression of it, and there are numerous quotations of which the authorship is either not given or indicated ambiguously.

But the chief criticism to which the book is open concerns its underlying attitude, which, though it appears overtly only here and there, can be felt throughout—the attitude, namely, that identifies present knowledge, so far as it goes, with truth. Whatever is is right, and ever will be, and whatever else was is wrong, and will never be again We are told, for example, that "the [relativity] theory must for ever remain ", and that "the assertion of the unity of all living things through the theory of evolution, is contradicted only by the ignorant or the intellectually vain" What one should learn from the history of science is that the fact that one is living now is a mere accident, and that the science of our time will appear to a historian of the future as crude as that of the seventeenth century appears to us, while some of the latter crudities (the transmutability of elements has already done so) may then have returned to displace our present superstitions The present time is an utterly undistinguished point in an indefinitely long sequence, it is not the culminating moment "for which the floating forceless ages waited" Unfortunately, few historians of science make this their central theme HERBERT DINGLE

PSYCHICAL RESEARCH

William James on Psychical Research

Compiled and edited by Gardner Murphy and Robert O. Ballou. Pp viii+339 (London Chatto and Windus, Ltd, 1961) 30*s* net

CONDITIONS in New England around the mid-nineteenth century were such as to throw up a number of people of exceptional talents Among them were the brothers James—William, investigator of the paranormal, and Henry, the novelist We are concerned here with the former, the elder of the two by one year They had much in common, especially a marked streak of pragmatism Its manifestations were different, practical and empirical for William, introspective and self-observational for Henry. So we find William taking Medical School at Harvard, and receiving an invitation to teach physiology to students, which soon led, as one would expect, to the borders of psychology and the associated problems of the mind

William James on Psychical Research deals with the last forty years (1870–1910) of William's life by presenting his papers, combined with an illuminating introduction and retrospect. The collection is valuable, more perhaps on account of the personalities involved than for the content of the contributions themselves. As a commentary on the state of psychical research, and indeed of much advanced philosophical thought of the period, it is admirable But if the reader is to enjoy these pages as he should—and as they deserve to be enjoyed—he might try the experiment of overlooking a good deal of the descriptions of séances, media, occult happenings and so on—which naturally aroused a fair amount of suspicion and controversy—and concentrate on the courage and sincerity of the people in question. We need pass no verdict on what they did, or what they thought it all meant what stands out is a monument of intellectual valour.

James was always asking 'Is it really so?" Herein lay his strength, devoted as he was to his friends and their common purpose. Not always could he go the whole way with them.

Seen against the background of the *fin de siècle*, one is struck by the power for good of Anglo-American co-operation: the foundation in 1882 of the Society for Psychical Research in England with a 'cell'—later a full society—in the United States.

In Great Britain the movement got away to a flying start with the active support of such figures as Henry Sidgwick, Edmund Gurney and Frederic Myers, not to mention Lord Rayleigh. Sidgwick's critical powers and Gurney's passion for hard work were essential, but the genius of the group was undoubtedly Myers, his life (largely) a tragedy and his death heroic. To his contemporaries he was a literary and historical scholar of exquisite sensibility, a Fellow of Trinity College, Cambridge, who, having no love for teaching, became an inspector of education. But as some will recollect his name as the author of the great poem *St. Paul*, the question can scarcely be avoided: What is the relation between these verses and his intense search for the nature of the survival of personality after death? We may never know, except to be humbled by the magnitude of the endeavour, for he was not one to count the cost or heed the wounds. Indeed, as Myers himself wrote: "Desperate patience of a brave desire."

An event of consequence, not mentioned by the compilers, was the short but brilliant life of the Metaphysical Society (1869–80). Among its members were Shadworth Hodgson, who founded the Aristotelian Society, and G. C. Robertson, who initiated *Mind*. Both those were closely connected with the Society for Psychical Research, having no doubt sharpened their wits and deepened their perception in discussions aforetime with such giants as Cardinal Manning, Father Dalgairns and Dean Stanley.

Meanwhile, James continued to press for experimental evidence. We gain little information as to how this was answered. There was much checking of mediumistic phenomena, trances and so on, but surely something more directly physical could have been attempted, even if the results were negative. It is worth remembering that the Einthoven string galvanometer appeared in 1903, and made possible an enormous increase in sensitivity for the measurement of minute electrical effects. Seemingly, comparatively little was done by direct instrumental means, or deliberate laboratory controls.

Prof. Gardner Murphy in the retrospect already mentioned, and writing about 1958, refers to four accomplishments of William James which make him a leading character in the history of psychical research. These are (i) he gave the subject the necessary prestige, (ii) he set things well and truly on their feet in the United States, (iii) he kept facts well to the fore, and (iv) he discovered the famous Mrs. Piper as a wholly exceptional medium. Now, long after the event, these do not appear to be very striking achievements, but in the intellectual climate of the time they counted for much.

But they were symptomatic of a fundamental quality. Prof. R. B. Perry wrote that James always "Knew there was more", and that is the outlook of the born explorer. Somebody once said to James, "the great field for new discoveries is always the unclassified residuum". (How forcibly indeed this was illustrated, for example, in the discovery of argon by Rayleigh and Ramsay.) Evidently it must be a basic tenet for students of the paranormal, from whatever direction they may approach it.

Nevertheless, it was left to Myers to pose the elemental question "Is the Universe friendly?". We cannot tell. What matters is that this timely volume shows William James and his circle following the light as they saw it, and leaving behind them a cherished example of dedicated research.

F. I. G. RAWLINS

CHEMISTRY IN INDUSTRY

Ammonia

Manufacture and Uses. By Dr. A. J. Harding. Pp. xiii+41+7 plates. (London: Oxford University Press, 1959. Published under the auspices of Imperial Chemical Industries, Ltd.) 6*s*. 6*d*. net.

Electrolytic Manufacture of Chemicals from Salt

By Dr. D. W. F. Hardie. Pp. xii+74+7 plates. (London: Oxford University Press, 1959. Published under the auspices of Imperial Chemical Industries, Ltd.) 7*s*. 6*d*. net.

THE books under review are the second and third in a series which is being published by Imperial Chemical Industries, Ltd., with the assistance of the Science Masters' Association and the Association of Women Science Teachers. The aim of the series is to help correlate academic chemistry as taught in schools, colleges and universities with chemistry as it is applied industrially.

Dr. Harding's book on ammonia has chapters on its manufacture, its properties and technical data, and its uses. There is also a bibliography and a short appendix on the application of physical chemical principles. The first chapter is by far the longest: it is concerned with the sources of the raw materials, the purification of hydrogen and nitrogen, and the actual synthesis process itself. Apart from the underlying chemistry, the mechanics and economics of the processes are briefly described.

Dr. Hardie, in his discussion of the salt industry, has chapters on the fundamentals of salt electrolysis, raw materials and energy, the manufacturing processes, packing, storage and transport of the products, production statistics and trends, physical and chemical properties of the products, principal uses of the products, and an outline of historical development. In addition, there are a bibliography, a brief list of important dates in the development of the industry, and a glossary.

Both volumes deal with their respective subjects clearly and in a way that should appeal to sixth-form student, university undergraduate and graduate alike. The authors bring home to the non-industrial chemist the interplay of chemistry, engineering and economics which is such an important part of industrial chemistry. Perhaps the most valuable service to the academic chemist is the way in which the authors show how the production of one particular chemical is co-ordinated with that of so many others in modern chemical industry. An example of this, quoted from Dr. Hardie's book, is that of chlorine production. Electrolytic chlorine production must go hand in hand with caustic soda production (sodium production is of relatively minor importance). However, recently the demand for chlorine for the production of chlorinated organic compounds has outstripped the demand for caustic soda. Hence investigations have been made into the aerial oxidation of the hydrochloric acid which is produced as a by-product of organic chlorination processes The academic chemist finds to his surprise that the obsolete Deacon and Weldon processes are likely to be resuscitated on economic grounds

These two books are well illustrated with line diagrams and plates The authors and publishers are to be congratulated on these books which keep up the high standard set by the first volume in this series *Sulphuric Acid Manufacture and Uses*, published by the Kynoch Press for Imperial Chemical Industries, Ltd in 1955 M J NEWLANDS

ISOTOPES IN HÆMATOLOGY

The Use of Isotopes in Hæmatology

By L G Lajtha Pp x+83 (Oxford: Blackwell Scientific Publications, Springfield, Ill Charles C Thomas, 1961) 21*s* net

THE application of isotopic techniques to hæmatological problems is standard procedure in modern medicine All too often their use has assumed the significance of a status symbol. Estimation of blood and plasma volume, the mean life-span of the erythrocyte and the absorption of radioactive cobalamin are procedures of established value There is therefore a place for an authoritative account covering these and related topics

The first two chapters of Dr Lajtha's book describe the estimation of plasma and red cell mass and the estimation of the mean cell life of the erythrocyte The next two are concerned with radioactive vitamin B_{12} and iron, and there are two short chapters on white cell and platelet tagging and autoradiography

The section on autoradiography is undoubtedly the best and reflects the author's vast experience in this field The technique of preparing autoradiographs is set out in precise detail and the description is warmly recommended to anyone proposing to work in this field The other sections are less happy The description and comment may well meet the need of the general hæmatologist who looks for guidance in setting up and interpreting tests involving the use of isotopes, but is unlikely to please the expert in the various fields

Surface counting techniques are mentioned in somewhat general terms, but a detailed account of how one should set about doing them and how to interpret the results is absent The estimation of mean cell life using chromium-51 is always of interest in a hæmolytic anæmia, but occasionally information about the site of destruction of the red cells may provide decisive information as to whether splenectomy is indicated or not Simultaneous iron-59 and chromium-51 studies, the former providing the additional information about the site of red cell formation, are often performed together and perhaps should have found a place in this book

Equally important is the emphasis the author places (or fails to place) on various procedures Both an *in vitro* and *in vivo* method for labelling red cells with chromium are described and little guidance is given as to which is the method of choice

Similarly, four methods of estimating absorption of vitamin B_{12} labelled with cobalt-58 are listed and discussed, namely, the fæcal excretion test, the urinary excretion test, the hepatic uptake test and the plasma test The change in plasma radioactivity after an oral dose of vitamin B_{12} does not merit consideration as a routine test of absorption of vitamin B_{12} even if material of sufficiently high specific activity were available It certainly has no place as a screening procedure On the other hand, many would regard the hepatic uptake of vitamin B_{12} labelled with cobalt-58 after an oral dose in a far more favourable light than does Dr Lajtha It is independent of the ability and willingness of the patient to collect his fæces (? for 15 days) or urine

Finally, a section devoted to the behaviour of the limited range of isotopes of use in the hæmatological laboratory and to the equipment that the hæmatologist could most profitably invest in in order to count these isotopes would have greatly enhanced the value of the book I CHANARIN

ZOOLOGICAL LITERATURE FOR 1958

The Zoological Record

Vol 95 Records of Zoological Literature relating chiefly to the year 1958 Edited by G Burder Stratton, assisted by Marcia A Edwards Pp v+2234 (London Zoological Society of London, 1961) 160*s*

THE present volume of *The Zoological Record*, relating chiefly to the literature of 1958, is bigger than ever, and provides good evidence, if this were necessary, of the great expansion of the subject in recent years The *Record*, apart from being a necessity to anyone engaged in taxonomic studies, also furnishes a good indication of the amount of work being carried out in the different groups of the animal kingdom In addition, the valuable system of classifying publications according to subject enables one to see the relative attention being devoted to the various aspects in each of the eighteen groups of animals listed A study of the Insecta, by far the largest section, comprising 660 pages, shows an increasing number of publications dealing with physiology and ecology, and in the subject index the number of pages under each heading is as follows: insect morphology 9, development 12, physiology 21, bionomics 10, ecology 19, evolution 8, geographical and faunistic 27 The main divisions show little difference from those in recent years Mollusca, with 187 pages, is followed by Protozoa 147, Pisces 141, Vermes 131, Mammalia 125, Arachnida 123, Aves 112, Crustacea 110, Amphibia 100, Reptilia 93, Trilobita 86 and in gradually diminishing size to Porifera 7 The number of new genera and subgenera is nil in Protochordata, one in Amphibia, and reaches a maximum of 949 in the Insecta It is noteworthy that the total number of new genera and subgenera has shown no diminution in recent years and as evidence of the amount of taxonomic work in progress does not support the pessimistic views of certain authorities concerning the dearth of taxonomists

This is the last volume to be issued in bound form Starting with Volume 96 (literature for 1959) the separate sections will be sent to subscribers as soon as they are published, a title-page and binding case will be forwarded when the volume is complete This will bring information of current research to users of the *Record* more quickly In addition, the format, beginning with Volume 96, will be changed to crown octavo, to give the larger type area necessary for recording the expanding volume of literature each year EDWARD HINDLE

Elsevier's Dictionary of Automation, Computers, Control and Measuring in Six Languages

English/American, French, Spanish, Italian, Dutch and German Compiled and arranged on an English Alphabetical base by W. E Clason. Pp. vi+848. (Amsterdam . Elsevier Publishing Company , London . D. Van Nostrand Company, Ltd , 1961) 140*s*

THE increase in technical and scientific knowledge has occasioned a crying need for multilingual technical dictionaries Bilingual technical dictionaries (many of which are of indifferent standard) are common enough, multilingual dictionaries are less common The present *Dictionary* is one more attempt to make good the deficit

There are 3 390 entries with an excellent index in each of the five non-English languages giving quick access to any of the entries in any of the languages used. Clearly, because of the extent of the scientific field covered, there must be a priority among the entries selected since it is not be to expected that 3,390 entries could cover such a number of highly specialized fields As with all choices, the present one cannot be expected to meet with wholesale approval or to be everyone's taste and must inevitably be a function of the compiler's bias Nevertheless I question why, for example, there are no entries for 'electronic counter', 'core', 'obey', whereas there are entries for "Westphal balance" and "mobilometer". On the other hand, it is only fair to point out that one welcomes the (unexpected) entries "tape travel" and "pigeon hole pocket". One might comment at random in this way but it does not detract from the fact that this appears to be an excellent addition to the long line of Elsevier multilingual dictionaries covering other scientific fields Its price may place it outside the average scientific pocket, but it will certainly be of help in the libraries of scientific and industrial research laboratories

The printing, binding and lay-out of the work are of the high standard and quality one has long come to expect from Elsevier. S. WHELAN

Practical Microscopy

By Dr C L Duddington Pp ix+237. (London Sir Isaac Pitman and Sons, Ltd , 1960) 30*s* net.

Histological and Histochemical Technics

By Prof Harold A Davenport Pp xxii+401 (Philadelphia and London W B Saunders Company, 1960) 49*s*

Section Cutting in Microscopy

By Dr H F Steedman Pp. vi+172. (Oxford Blackwell Scientific Publications, Springfield, Ill . Charles C Thomas, 1960) 21*s* net

SO many books on microscopy and microscopical technique have appeared in the past few years that new publications on these subjects may seem unwarranted All three books reviewed here, however, seem to have much to justify their publication Dr Duddington has addressed his work to the serious amateur, and to the elementary student of biology He assumes no previous scientific knowledge, and introduces the reader in turn to the component parts of the microscope and to some of the basic techniques of microscope manipulation The second part of the book consists of an introduction to the methods of preparing botanical, zoological and bacteriological specimens for investigation There is a short bibliography, listing most of the standard reference works on the subject, some of which may, however. prove too technical for those who have only just taken up this type of study. Perhaps a future edition might grade the references and indicate those likely to prove most useful for elementary students. The book is well produced and clearly illustrated.

Histological and Histochemical Technics, by Prof Davenport, is designed for the advanced worker, and is concerned entirely with methods of preparing specimens It provides a survey in some detail of the processes of fixation, embedding and staining, including an extensive discussion of their more theoretical aspects as well as the actual formulæ One useful chapter describes techniques of staining in the block, a method of preparation which seems to attract comparatively little interest at the present. The final chapters are devoted to a brief survey of histochemical methods. and would serve as a good introduction and source-book for those who use such methods only occasionally

Section Cutting in Microscopy, by H F Steedman, is a book largely for the expert It presents details of all the usual methods of microtomy, in addition to describing several new techniques developed by the author The approach is logical throughout and the author has made a most commendable attempt to rationalize some of the more common microscopical techniques It is pleasing to see the inclusion of a section on possible faults which may present themselves during the cutting of paraffin sections Other chapters deal very fully with the use of ester waxes, the water-soluble waxes and with the use of urea formaldehyde resin There is also a chapter on the preparation of ultra-thin sections for electron microscopy This book is a welcome addition to the reference works which one expects to find in every histological laboratory S BRADBURY

The Theory of Crystal Structure Analysis

By A. I Kitaigorodsku Translated from the Russian by David and Katherine Harker Pp. xi+275 (New York : Consultants Bureau, Inc , 1961) 12 50 dollars

IN the preface of this book, which appeared in the original Russian version in 1957, the author makes it clear that he is describing his subject-matter up to the year 1955 It is perhaps a tribute to the rate of development in this field that many of the author's analyses and opinions seem either outmoded or bizarre at the present time In particular, the analyses concerned with distribution functions have been repeated more formally and elegantly in the past few years ; the author also dismisses anomalous dispersion as of 'no importance' and the difference synthesis as 'devoid of interest' (this even drew a translators' comment).

However, much of the book is devoted to the basic theories of the Patterson method, intensity statistics and direct methods and, for these, lack of topicality is of less consequence The treatment of these topics is such as will commend itself either to the crystallographer of mathematical inclinations or to the mathematician with some knowledge of crystal structure analysis The section dealing with inequality relationships is of particular interest, being concerned. to a large extent, with the author's own excellent work. The book reads well, which is symptomatic of the quality of the translation.

To summarize. a work of considerable interest to those able to appreciate it and one the main faults of which are due to the lapse of time since it first appeared. M M. WOOLFSON

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS*

By Sir HOWARD FLOREY, F.R.S.

AWARD OF MEDALS, 1961

Copley Medal: Sir Hans Krebs, F.R.S.

SIR HANS KREBS has made outstanding contributions to knowledge of the chemical pathways of metabolism. In 1932, with Henseleit, he used tissue slices to demonstrate the synthesis of urea and found that additions of ornithine stimulated the process. Ornithine was regarded as uniting with carbon dioxide and ammonia to give arginine, with citrulline as an intermediate. The enzyme arginase liberated urea and a molecule of ornithine, so that the process could begin again. Subsequent research has shown that the postulated cycle is essentially valid, although more detail has been introduced, carbamyl phosphate, argininosuccinate and adenosine triphosphate have been brought in and aspartic acid has replaced ammonia in the reaction with citrulline. The more complicated version owes much to the fundamental work initiated by Krebs in 1937 on the tricarboxylic acid cycle. This process is now seen as the main route for oxidizing the two-carbon fragment produced in the biological degradation of carbohydrates, fatty acids and amino-acids.

The initial acceptor of acetyl coenzyme *A* is oxalacetate and the completion of the cycle is marked by regeneration of a molecule of oxalacetate, and by the oxidation of one C_2 fragment to carbon dioxide and water. The product of the interaction of oxalacetate and acetyl coenzyme *A* is citric acid, and the later steps in the cycle result in the liberation of carbon dioxide and pairs of hydrogen atoms. These latter finally unite with oxygen to form water but the intermediate stages are coupled with the formation of adenosine triphosphate from adenosine diphosphate. The Krebs cycle does not allow for the net synthesis of the intermediates, which are themselves important in providing the carbon framework for many biosyntheses. The main cycle therefore needed to be reinforced by postulating ancillary mechanisms leading to the synthesis of available four-carbon intermediates. Krebs's work on the glyoxylate cycle showed that iso-citrate, by yielding succinate and glyoxylate, permitted the formation of malate by the interaction of acetyl coenzyme *A* and glyoxylate. The malate led directly to the oxalacetate needed by the main cycle, and the succinate could be used as a precursor or could permit the replacement of intermediates drawn out of the cycle by synthesis of cell substances.

The very complex overall picture is both useful and elegant. Nobody deserves more credit for this than Krebs.

A Royal Medal: Prof. C. F. Powell, F.R.S.

Prof. Powell is distinguished by his outstanding contributions to our knowledge of cosmic rays and of the fundamental particles.

He started research under Prof. C. T. R. Wilson and made important contributions to the problem of condensation of water vapour to form drops at elevated temperatures. He then worked with Prof. A. M. Tyndall at Bristol on the mobility of positive ions in gases. This was a difficult subject, bedevilled by the effects of impurities, and Tyndall and Powell raised it to new levels of definiteness and reliability.

About twenty years ago Powell turned his attention to the development of the use of photographic techniques for studying the interactions and other properties of fast particles. Up to that time such techniques were rarely used but, through collaboration with those concerned with the production of photographic emulsion, Powell established a new and powerful technique which ever since has played a most important part in the study of energetic particles.

The first applications were to the study of nuclear interactions, but quite soon the technique was applied to investigate cosmic radiation. This soon resulted in the discovery with Occhialini of the π-meson by analysis of the tracks of cosmic ray particles in emulsions exposed at high altitude in the Bolivian Andes. Further major discoveries followed from the work of the laboratory at Bristol which was so enthusiastically led by Powell. These included the τ-meson and evidence for the decay of neutral mesons into γ-radiation. Improvements in emulsion technique to increase the rate of detection of fast electrons resulted in the recent observation of multiple meson production in nuclear encounters.

Apart from these outstanding individual discoveries, Powell and his collaborators have made a great number of significant contributions to many aspects of cosmic ray and fundamental particle studies. They have introduced new and improved techniques whenever the scope of existing techniques has become inadequate. Thus they developed the use of balloons to carry emulsions to high altitudes for cosmic ray studies and they introduced the emulsion stack which made it possible to follow the tracks of very fast particles, right through to their end-points.

With the introduction of artificial accelerators capable of providing beams of particles of energy comparable with the main bulk of cosmic ray particles, Powell and his group have turned part of their attention to fruitful use of emulsion stacks to study, in more detail than hitherto, the properties of mesons and hyperons. They have, however, taken up as well the difficult problem of studying the ultra-high-energy cosmic radiation and already have obtained information of interest.

Powell has not only made many outstanding personal contributions to this work but has been, through his enthusiasm and organizing ability (which has involved large-scale international co-operation), a continual source of inspiration to everyone concerned. The pioneering work at Bristol has been, and will continue to be, of the greatest importance in the physics of high-energy phenomena and of the fundamental particles

---

* Delivered at the Royal Society on November 30.

A Royal Medal. Sir Wilfrid Le Gros Clark, F R S

Sir Wilfrid Le Gros Clark is internationally known for his work in two apparently unrelated fields, namely, neuro-anatomy and primate evolution However, an important feature of his neurological work has been the way in which he has used the evidence of comparative anatomy to shed light on the evolution of the human brain His work on the connexions of the thalamic nuclei with the cortex and the hypothalamus is especially noteworthy in this respect He and his collaborators have studied the inter-relationships of various parts of the brain using in particular methods depending on retrograde and trans-neuronal degeneration He was able to show that following a small retinal lesion, localized patches of atrophy appeared in the lateral geniculate body and by these means he mapped the projection of the retina on the lateral geniculate body and on the cortex Other investigations of this type have added considerably to our knowledge of the olfactory system and have removed misconceptions concerning the relationship between the hippocampus and the rhinencephalon

Le Gros Clark is generally recognized as a leading authority on primate evolution His early work on the anatomy and behaviour of *Tarsius*, based on painstaking personal observations in Borneo, is a model of its kind During the past fifteen years he has played a leading part in the examination of many important fossil discoveries, especially in Africa His critical assessment of the Australopithecinae and the tentative conclusion that they may be closely related to the ancestral stock from which the Hominidae are derived, is one of the landmarks in this branch of anthropology He was also closely associated with the unmasking of the Piltdown forgery, thus helping to remove a puzzling discrepancy from discussions on human evolution

Apart from these major fields of work Le Gros Clark has contributed much to general anatomical and biological problems His work on muscle regeneration, for example, showed elegance and clarity, and as honorary director of the Medical Research Council Ergonomics Research Unit he has supervised research in a new and expanding field and has given a new impetus to applied anatomy

Davy Medal Prof D H R Barton, F R S.

Prof Barton's researches have for the most part been concerned with the chemistry of natural products, a field which has provided him with numerous opportunities to demonstrate his brilliance in the elucidation of complex structures, the unravelling of stereochemical complications, and the elaboration of syntheses He has always taken every opportunity to make good use of physical methods in solving problems of organic chemistry, and much of his earlier work on the applications of differences of molecular rotation, particularly in the terpene and steroid fields, has had far-reaching effects on our knowledge of stereochemical relationships. His pioneering work on conformational analysis in alicyclic systems has revolutionized concepts of the relationship between stereochemistry and reactivity More recently he has been studying long-range effects, by which, for example, a remote ethylenic linkage can exercise a marked influence on the condensation reactions of a carbonyl group in a triterpene system

His notable contributions to the establishment of the structure and intricate chemistry of caryophyllene have been followed by fruitful investigations on many other sesquiterpenes, such as tenulin, pyrethrosin, lactucin, and geigerin, while in the di- and tri-terpenoid series partial or complete structures have been established for a substantial number of natural products, these include the citrus bitter principle, limonin, the structure of which had defied elucidation for a considerable time, and clerodin, also a bitter principle His investigations on steroids and their derivatives have been prolific, and include some particularly elegant work on cevine and related steroid alkaloids The biogenetic mechanisms by which natural products are built up from simple precursors in Nature have interested him for some time, and studies on these processes led to a simple two-stage synthesis of usnic acid from methylphloracetophenone

The most remarkable results of his researches have probably been those arising from his investigations on the photochemical transformations which sometimes occur when compounds are irradiated with ultra-violet light The classical work carried out more than sixty years ago on the irradiation of santonin gave some indication of the problems involved in studying such reactions, but Barton has succeeded in establishing the structures of the three products, isophotosantonic acid lactone, photosantonic acid, and lumisantonin, and has explained mechanistically the remarkable ways in which these unusual compounds are derived, he has shown, furthermore, that other *cyclo*hexadienones, such as prednisone, behave similarly Quite recently he has used photochemical methods to bring about an attack, by a group in a favourable stereochemical position, on a non-activated carbon atom, and by most brilliant applications of this method he has achieved spectacular syntheses of aldosterone acetate (in three stages from corticosterone acetate) and of 19-noraldosterone acetate Perhaps even more remarkable is his beautiful synthesis of conessine, in which the heterocyclic ring involving C_{18} is formed by photolysis of a steroidal C_{20} azide

The brilliance and originality of Prof Barton's work has gained him an international reputation and his laboratories at the Imperial College of Science and Technology have become a rendezvous for research workers from many countries

Sylvester Medal Prof P Hall, F.R.S

In his first two papers on finite group theory, Prof Hall broke new ground in the fields of soluble groups and groups of prime-power order In 1928 he established the validity of soluble groups of some striking extensions of the classical theorems of Sylow, thereby opening a new epoch in the study of finite soluble groups Five years later he laid the foundation for all subsequent work on groups of prime-power order with a long and systematic paper, the many original and fruitful ideas of which included that of the regular *p*-group In the years between the appearance of these landmarks in the history of group-theory and the War he published many other papers on groups of finite order

The culmination of this extremely productive period occurred at the group-theoretical colloquium at Gottingen in June 1939, the central feature of which was a series of lectures by Hall, afterwards published in *Crelle's Journal* in 1940. His expositions of a classification theory for prime-power groups and of a structure theory for soluble groups, and his papers on automorphism groups and on verbal and marginal subgroups, have taken their place in the canon of essential material for any student of finite groups, and together embrace many of the leading themes of his work up to that date.

Hall's election into the Saldeirian chair of pure mathematics at Cambridge in 1953 marked the beginning of another sequence of publications of the greatest importance. In the intervening years much work had been done—notably by Russian mathematicians—on extensions and generalizations of Hall's theorems on soluble groups, and in 1956 Hall gave a systematic account of these and earlier results on the existence, conjugacy and inclusion properties of subgroups with coprime orders and indices, adding many new results of his own. Another remarkable work on finite groups, carried out in collaboration with Graham Higman, dealt with p-soluble groups and had as its most striking application certain reduction theorems for a celebrated conjecture of Burnside's.

Hall's researches have thrown much light on the interrelation of various finiteness conditions which may be imposed on groups of infinite order, and they have been illustrated by many examples constructed to delimit the range of applicability of the results. Among other types of infinite group considered by Hall may be mentioned Abelian-by-nilpotent groups, locally finite groups and periodic FC-groups.

Hall's influence on British algebraists—of whom he is the acknowledged doyen—has not been confined to specialists in the branch of algebra with which Hall's name, like that of his forerunner Burnside, will be enduringly linked.

Hughes Medal: Prof. A. H. Cottrell, F.R.S.

Prof. Cottrell's contributions to the field of structural metallurgy have been outstanding whether they be regarded from the point of view of the physicist, the metallurgist, or the engineer. Utilizing to the full the current methods of the physics of metals, and in particular the pioneer work of Taylor, Mott and Frank on dislocations, Cottrell has been able to explain, in a remarkably clear physical manner, many important mechanical properties of metals. Typical of this work is his early explanation of the yield-point phenomena in steels, which he showed to be associated with the anchoring of dislocations by solute atoms. He has become a leader in the understanding of the many and decisive ways in which crystal defects, particularly dislocations and vacant atomic sites, control the behaviour of metals in practice.

Engineers and physicists alike owe much to Cottrell's books on *Dislocations in Crystals* and on *Theoretical Structural Metallurgy*. Remarkable for their clarity of thought and composition, they have been a major cause of the current trend towards a more fundamental understanding of their materials by both engineers and metallurgists. In the past decade, British metallurgy has found much inspiration in the work of Cottrell and his associates.

In recent years Cottrell has given attention to irradiation problems arising in nuclear power developments. He has applied his ideas to the effects of irradiation on the properties of both metals and non-metals, and his name is particularly associated with irradiation-induced creep in anisotropic materials such as uranium; but much more than this has been done. It is fair to say that the effects of irradiation on the growth, swelling and creep of uranium, on precipitation in alloys, brittle fracture of steel, and energy storage in graphite have now a solid theoretical background which is largely due to Cottrell.

Leverhulme Tercentenary Medal: Sir Cyril Hinshelwood, F.R.S.

This is the first occasion on which the Leverhulme Medal has been awarded. It will therefore be appropriate to remind Fellows of the circumstances in which it was instituted. In 1960 the Council of the Society accepted an offer from the Trustees of the Leverhulme Trust Fund of a gold medal to mark the tercentenary of the Society. The medal has been named the Leverhulme Tercentenary Medal and is to be awarded every three years to the individual who, in the opinion of the Council, has made the most significant contribution in the field of pure or applied chemistry or engineering. The first Leverhulme Tercentenary Medal has been awarded to our immediate past president, Sir Cyril Hinshelwood.

Few working scientists to-day have not profited from a study of one or more of the profound and far-ranging contributions which Sir Cyril Hinshelwood has made to the advancement of natural knowledge. The range of his interests and attainments is enormous and he has touched nothing which he has not adorned. His publications illustrate not only the diversity of his learning and culture but also its basic unity.

The Leverhulme Tercentenary Medal is being awarded to him for his contributions to pure and applied chemistry. For several decades he has been recognized as one of the leading physical chemists of the world. His work on chemical kinetics is classical; it has combined simplicity and elegance of experimental approach with far-ranging theoretical implications.

He first clarified the mechanism of reactions in the gaseous phase in terms of molecular collisonal processes and molecular activation, and directed attention to the essential characteristics which arise from chain propagation in thermal systems. This work has since stimulated the application of many other methods to the determination of intermediate reactive species. He has made similar contributions to our understanding of reaction mechanisms in both the liquid and solid phases. By applying the same principles to systems involving bacterial growth he has been able to separate phases in the growth process and to examine the effect of inhibitors and the mechanism of drug resistance, and the effect of varying growth media on the growth process. He has investigated the cellular content of nucleic acids during the growth cycle and also the specific effect of elements such as potassium, sodium, phosphorus and sulphur. These researches make common ground between the chemical and biological sciences. Nor has his work been confined to basic science; he has done memorable things in the application of chemistry to useful ends.

He has not only worked as a scientist but, tirelessly, for scientists; for the University of Oxford, for international science, for scientific societies in general and for the Royal Society in particular.

We rejoice that the Leverhulme Medal is being given to a most eminent chemist, and we regard it as particularly happy that a medal which commemorates the tercentenary is going to the man who presided over that great event with such eloquence, dignity and grace.

ACTIVITIES OF THE ROYAL SOCIETY

It is a pleasure at the end of a year of office to record that I can heartily endorse all that has been said by my predecessors of the admirable way in which the interests of the Society are fostered by Dr. Martin and his staff. The smooth running of its many activities depends to a very large extent on their efforts and I personally am greatly indebted to them for all the help I have received during the past year.

The tasks of my fellow Officers are many and various. We are all very grateful to the Treasurer for the care and attention which he has devoted to the Society's affairs. The Secretaries not only have had to work with their accustomed vigour at their increasingly heavy tasks, but they have had to exercise more than their usual forbearance in dealing with my many naïve questions. I am sure the Society would wish me to thank all these Officers for their work on its behalf.

The Officers and Council always hope that the report of Council has been read by the Fellows, and in any case you will not want me to give you now a catalogue of the Society's activities. There are, however, one or two points which call for comment.

The Society has been so fortunate as to receive a great benefaction from the Wellcome Trust for the establishment of a professorship. We are, indeed, very grateful for this gift, and we are delighted that the name of Sir Henry Dale is to be permanently associated with it, for he has ably served not only the Wellcome Trust but also the Society and, indeed, science generally.

During the past year a number of Fellows have devoted considerable time to surveying the needs of biological research in Britain. Their survey leaves little room for doubt that much more could be done to encourage advances in fundamental knowledge and to foster their application. This may well apply to many branches of physical science as well.

The earning of the national living becomes increasingly difficult in a fiercely competitive world, and it would seem to be self-evident that the country should be straining every nerve to foster science and technology. We must therefore deplore the evident signs that some scientific activities, which to a large extent depend on Government aid, are to be curtailed, or at least are not to be allowed to expand at the present time. Even if this is a 'temporary measure', as it is claimed to be, damage is being done to the confidence of scientists and technologists. They observe that those who control the situation have apparently not yet recognized that the brains of the citizens are one of our greatest remaining national resources, and that the country's future prosperity will be, in a large measure, dictated by the use that is made of this asset.

There are good grounds for believing, for example, that the creation of new senior scientific positions, such as professorships in universities, is not even keeping pace with the expansion in the number of undergraduates. The opinion has been expressed by many Fellows that Britain particularly needs more professorships equipped with adequate research facilities if it is to give reasonable and proper encouragement to all its best men and women. Perhaps we can all do something towards letting it be widely known that we are by no means satisfied with the present overall position.

The maintenance of relations with foreign academies and scientists is one of the important activities of the Royal Society. During the past year this phase of our work has been fully maintained. There have, for example, been visits from Russian and Chinese colleagues, and in September very successful meetings of the Bureau, Executive Committee and General Assembly of the International Council of Scientific Unions were held in London under the sponsorship of the Royal Society. It is very much in the mind of Council to increase as much as possible all activities which impinge even remotely on maintaining contact with colleagues both from the Commonwealth and from other countries. We can only hope that we shall be able to secure means adequate for the task. Not the least of our problems is lack of accommodation for this and other responsibilities that we seek to discharge. Although I cannot give any satisfactory assurances on this point now, strenuous efforts are being made to try to overcome this very serious handicap.

EXCHANGE OF SUBSTANCES BETWEEN THE BLOOD AND TISSUES

On these annual occasions the President has commonly taken the opportunity to make some remarks about matters of scientific interest. This, I suspect, is done mainly to demonstrate that he is not entirely out of touch with scientific experiment. More than once a President has pointed out the impossibility of having a sufficiently wide knowledge to comment adequately on the many outstanding scientific discoveries that are being made under modern conditions. In following in the presidential footsteps, I have been considerably influenced by the remark made by one of my more candid friends, that I was not so highbrow as my predecessors, and by a

Fig. 1. The first illustration of the capillary circulation with its legend. Malpighi described the capillary circulation in a frog's lung in a letter to Borelli which was published in 1661

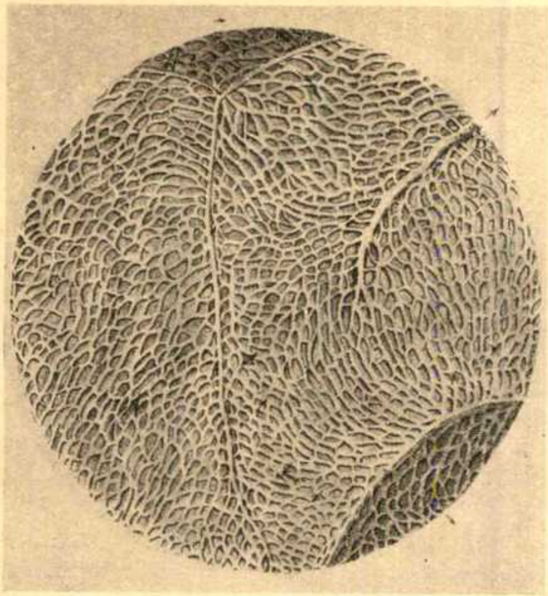

Fig. 2. The capillary circulation in a frog's lung, from a work published by Marshall Hall in 1831 entitled *A critical and experimental Essay on the Circulation of the Blood, especially observed in the minute and capillary vessels of the Batrachia and of Fishes*

comment of another colleague after I had had the honour of delivering a lecture to the Society—he said that it had been a good idea to turn the lights on and off frequently as it kept everyone awake.

Following these hints, therefore, my aim is very modest in that I propose to review and to illustrate briefly some researches in biology the history of which is almost exactly coeval with that of the Royal Society, and which have been greatly influenced by the development of special physical techniques during the past ten years.

In 1628, Harvey published his great work demonstrating the circulation of the blood with irrefutable clarity. The blood left the heart by the arteries and returned to it by the veins. It was not, however, until 1661 that an Italian, who a few years later became a Fellow of the Royal Society and whose portrait now hangs in the Society's house, discovered the vessels which connect the arteries to the veins. I refer, of course, to Marcello Malpighi. By means of his very early compound microscope he observed in the living animal what we now know as blood capillaries.

He saw and illustrated the branching of the pulmonary artery to form a network in the walls of a vesicle in the lung of a frog. The network united to join a pulmonary vein (Fig. 1).

Another Fellow of the Royal Society, Antony van Leeuwenhoek, amply confirmed and greatly extended Malpighi's observations in a large number of species, so that by 1688, in which year Leeuwenhoek sent a letter to the Royal Society describing his observations, there was sufficient evidence to justify the conclusion that blood capillaries were present in all the tissues of animals with a blood circulation.

No great progress was made in the next century and a half in the understanding of the structure of the smallest blood vessels. In 1831, Marshall Hall, a Fellow of the Society who has some claim to have discovered reflex nervous action, wrote: "It is singular that in the midst of the dispute concerning the irritability of the capillaries, there should be a doubt whether the vessels be real tubes or mere canals. There are many reasons which incline me to the latter opinion". That is to say, he thought that they were probably mere spaces in the tissues rather than tubes with their own distinctive wall (Fig. 2).

The knowledge of the structure of the capillary wall was strikingly expanded about the middle of the nineteenth century by the discovery that treatment of the blood vessels, including the capillaries, with dilute silver nitrate resulted in the appearance of a network, which was rightly considered to represent the boundaries between contiguous lining cells. This layer of lining cells, which has proved to be present in all the vessels of the body, was given the name of endothelium (Fig. 3).

As a result of this and other histological observations, the walls of the capillaries were conceived of as being composed of a mosaic of flat cells which were joined together by a cement substance, represented by the material stained black by silver nitrate. In these vessels there are few supporting cells, and the wall is, in effect, composed of endothelial cells with such fibres and tissue matrix as may be closely apposed to them.

It is through the walls of the fine blood vessels that most of the important exchanges of material between the blood and the tissues take place. The walls of the fine blood vessels appear to form a membrane which is freely permeable to gases, such as oxygen and carbon dioxide, which pass to and fro by diffusion. It is thought that substances like sodium chloride and glucose also pass freely, but that the normal capillary wall is almost, though not quite, impermeable to proteins. Ernest Starling, at the end of last century, adumbrated the theory that the capillary wall was of the nature of a semi-permeable membrane, across which the plasma proteins were able to exert an osmotic pressure, and that normally there was a near balance between the hydrostatic pressure of the blood tending to filter fluid out of the vessels and the osmotic pressure of the plasma proteins tending to draw fluid in from the surrounding tissues. This theory of Starling's was given strong support by the experiments of Landis, who measured directly the forces involved, but although Starling's theory is still almost universally accepted it has not been immune from criticism.

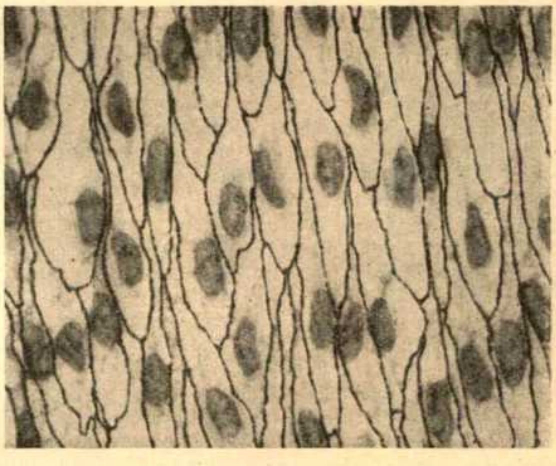

Fig. 3. Endothelium lining the aorta of a rabbit, viewed *en face*. The flat nucleated cells have been outlined by treatment with silver nitrate. (× 390)

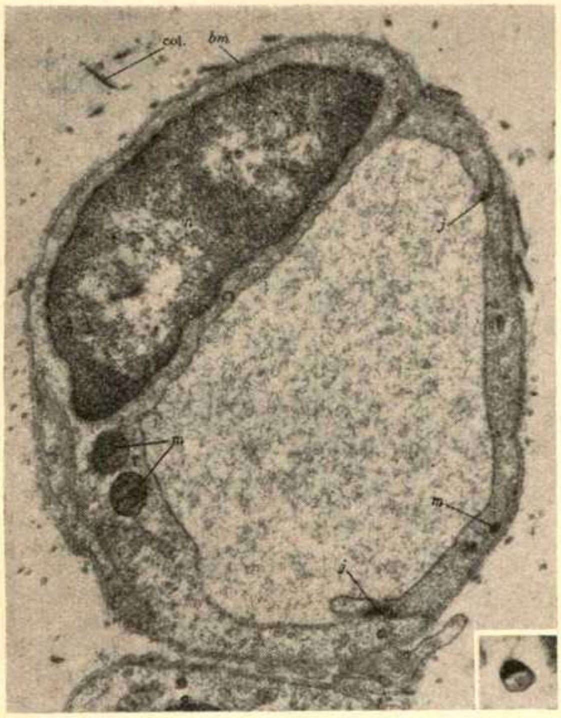

Fig. 4. Electron micrograph of a capillary, seen in cross-section, from the subcutaneous tissue of a guinea pig. At this site the wall is composed of parts of two cells; and a nucleus (*n*), mitochondria (*m*), two cell junctions showing adhesion belts (*j*), and many cytoplasmic vesicles can be seen. A basement membrane (*bm*) surrounds the vessel, and external to it collagen fibres (col.) have been cut longitudinally and transversely. (× 12,600.) Inset is a cross-section of a similar capillary viewed with a light microscope with a 2-mm. oil-immersion objective. (× 780)

Much attention has been directed to the detailed structure of the living membrane which was thought to have these semi-permeable qualities. When viewed in cross-section by the light microscope with a 2-mm. oil-immersion lens the capillary wall seems to be composed of a very thin membrane with little recognizable structure except for the nuclei of the endothelial cells, which make a bulge where they occur (inset to Fig. 4.). A basement membrane composed of polysaccharide, and not clearly differentiated from what is known as the pericapillary sheath, is also recognized as a regular constituent of the fine blood vessels.

It was conceived by some that the exchange of water and dissolved solids between the blood and the tissues took place through hypothetical pores in the intercellular cement which, on the basis of the appearances produced by silver impregnation, was thought to be present in substantial amounts. Others believed that minute pores existed in the cytoplasm of the endothelial cells themselves through which substances escaped from the blood. If either of these views were correct, it would not be difficult to visualize conditions in which Starling's hypothesis would be easily credible.

Work during the past ten years has added considerably to our knowledge of the structure of the capillary wall, knowledge which necessitates examining old theories further. This work is a good example of the influence of progress in one science on that in another. Our increased knowledge is due essentially to the invention of the electron microscope, for this remarkable instrument has opened up entirely new possibilities to the biologist who is attempting to correlate structure and function.

Another branch of the physical sciences is also involved in making this possible, for biologists are indebted to polymer chemists for embedding materials in which tissues can be cut sufficiently thin to be examined in the electron microscope.

The electron miscoscope reveals that the membrane forming the wall of a capillary, which is apparently almost structureless and might be likened to a piece of 'Cellophane' when observed in the light microscope, is composed of cells with all the usual cellular organelles (Fig. 4). As well as the nucleus there are small mitochondria, a Golgi complex and a centrosome. There are granules of ribonucleoprotein which are sometimes free and sometimes attached to vesicular structures. The junctions between the cells are regular narrow gaps about 200 Å. wide, and there is no sign of the apparently substantial band of intercellular cement substance which was thought to exist. At the cell junctions there is an electron-dense area which is known as an attachment belt or desmosome. It is thought to be the region at which the cells are most firmly attached to one another. Surrounding the vessel is a basement membrane which apparently contains very fine fibrils.

Palade, the first observer of capillary structure by the electron microscope, described intracellular vesicles which, though found in other cells, are particularly prominent in endothelium. On the luminal surface of the endothelial cell there are indentations of the bounding membrane known as caveolæ intracellulares. Similar caveolæ exist on the external surface of the cell. Between these, two surface profiles of vesicles, which are usually some 500–600 Å. in diameter, can be recognized in the cytoplasm of the cell (Fig. 5).

Palade proposed the theory that fluid is transported from the lumen of the capillary to the outside by means of these structures. According to this theory, a minute amount of plasma is enclosed in the caveola, which is then pinched off by a membrane to form an intracytoplasmic vesicle. The vesicle is ferried across the cytoplasm to be discharged on the external surface beneath the basement membrane. It is difficult to see how the cells of the capillary wall can exercise

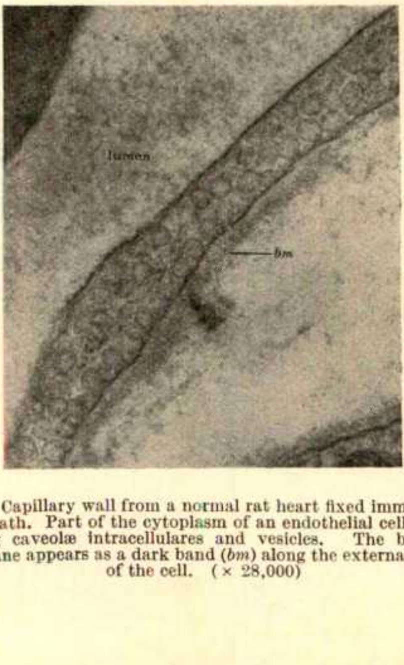

Fig. 5. Capillary wall from a normal rat heart fixed immediately after death. Part of the cytoplasm of an endothelial cell is seen, showing caveolæ intracellulares and vesicles. The basement membrane appears as a dark band (*bm*) along the external surface of the cell. (× 28,000)

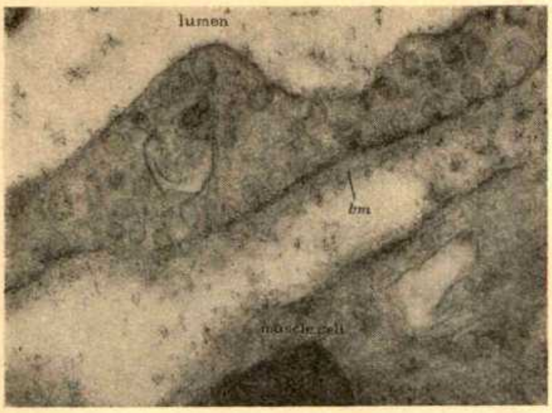

Fig. 6. Capillary from a rat heart perfused for 15 min. with saline solution containing particles of saccharated iron oxide. Particles are present in the lumen of the vessel and in the pericapillary space. They can be seen in the caveolae intracellulares on both the luminal and external surfaces of the cell, and in vesicles in the cell cytoplasm. *bm*, basement membrane. (× 33,600)

selective permeability if this is the mechanism for fluid transport, since the vesicles are very much bigger than protein molecules. To meet this difficulty Palade proposed that the selective permeability of capillaries resided in the basement membrane, which is usually a well-marked feature in the capillary wall.

Palade and Wissig attempted to show that the vesicles did, in fact, constitute a transport mechanism by injecting into the blood stream the protein ferritin, the large molecule of which contains sufficient iron to make it opaque to electrons. They found that ferritin molecules could be seen in some of the vesicles but that they also lay free in the cytoplasm. Later Palade used colloidal gold in the same way, and stated that the particles of colloidal gold were always found within the vesicles and not free in the cytoplasm, and he inferred that fluid must be transported through the endothelial cells in the vesicular system.

One of the difficulties attending such observations is to procure a sufficient concentration of the electron-opaque particles to act as efficient markers, but this can be overcome to a certain extent by the use of perfused organs. It is a standard pharmacological technique to make an isolated rat or rabbit heart beat for hours by perfusing it with a suitable oxygenated saline solution. It is possible, without stopping the heart beat, to add to the perfusion fluid a considerable amount of colloidal thorium dioxide or colloidal ferric hydroxide, the particles of which are, of course, opaque to electrons. Using such a preparation, Jennings and Marchesi have shown that the particles of ferric hydroxide pass into the open mouths of the caveolæ intracellulares on the luminal surface of the endothelium, and that they appear in the vesicles, in the cell cytoplasm, and in the caveolæ which open at the external surface. It seems fairly certain that these particles are in passage across the cell in the vesicular system in the manner proposed by Palade. There is not much evidence that the particles pass between the cells at the intercellular junctions. After they have passed through the cell there is no evidence from electron micrographs that the basement membrane forms much of a barrier to these particles, so that it is difficult to conceive that it would do so to molecules of protein (Figs. 6 and 7).

One may, therefore, picture the formation of caveolæ and vesicles as a process which is continuously altering the capillary wall and passing fluid from the lumen through into the tissue spaces. It is probable that the caveolæ are too large to account for the semi-permeable qualities of the endothelial membrane. The electron microscope, although its resolving power is sufficient to do so, has not revealed any smaller channels passing from the lumen to the outside of the capillary. Such channels would be necessary in a membrane which was semi-permeable by reason of the size of the pores in its structure. It still remains, therefore, to be explained in what structure or mechanism the semi-permeability of the normal capillary wall resides.

A morphological discovery entirely due to the electron microscope is that the capillaries do not have the same structure in all parts of the body. Those in the glomerulus of the kidney have small fenestrations through the cell cytoplasm, and those in the endocrine organs such as the pituitary body, the adrenals and the thyroid gland have gaps in the cytoplasm which are filled by a very tenuous membrane. Similar capillaries are found in the small and large intestines. There is no evidence, except in the case of the kidney, that these gaps are particularly permeable to proteins and their significance is not yet understood.

During the past forty years it has been demonstrated that certain substances which occur in the tissues of animals, such as histamine, 5-hydroxytryptamine, and bradykinin, have the property, when they are applied at great dilution, of making blood vessels more permeable than normal to proteins. Swelling or œdema is an important feature in many natural inflammations, such as those produced by bacterial invasion, and it is possible that substances of this nature which seem to be liberated in injured tissues are responsible for the increased permeability of the capillaries to proteins, leading to the accumulation of extravascular fluid. Majno and Palade have recently examined the small blood vessels in the cremaster muscle of the rat after it had been subjected to the influence of dilute solutions of the vasoactive substances that I have mentioned. They could find no

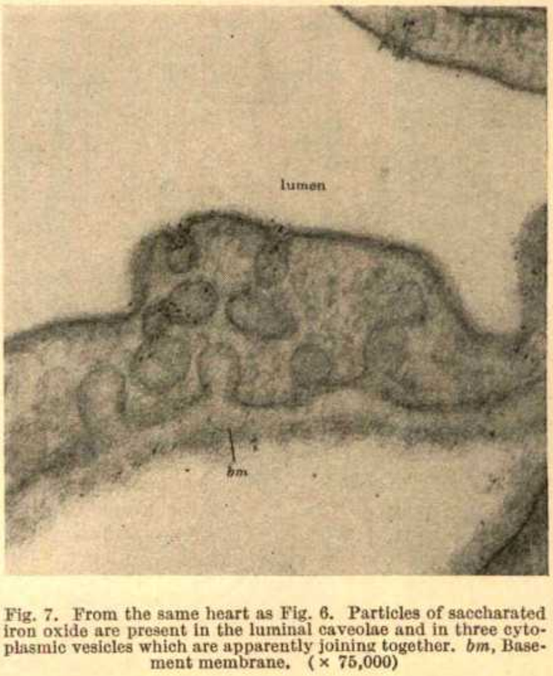

Fig. 7. From the same heart as Fig. 6. Particles of saccharated iron oxide are present in the luminal caveolae and in three cytoplasmic vesicles which are apparently joining together. *bm*, Basement membrane. (× 75,000)

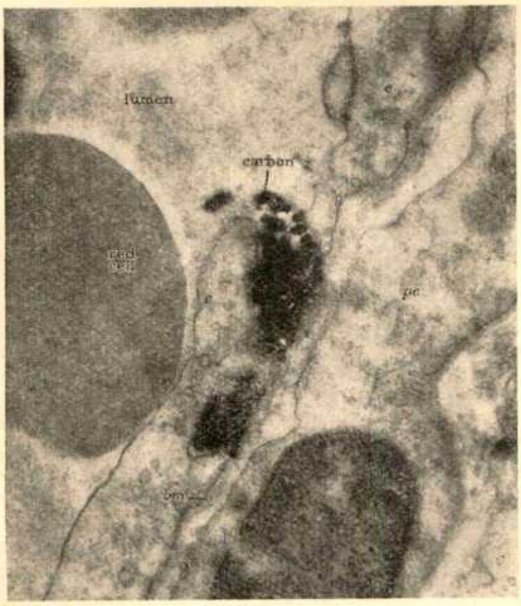

Fig. 8. Venule in the mesentery of a rat. A suspension of carbon was injected intravenously 1 min. after the mesentery had been inflamed by mechanical injury, and the tissue was fixed 3 min. later. Carbon particles have passed into a space in the vessel wall which may well be at a junction between two endothelial cells. *bm*, Basement membrane; *e*, endothelium; *pe*, periendothelial cell. (× 24,600)

alteration in the vesicular structures of the endothelium, and no holes through the endothelial cytoplasm itself, but there were discontinuities in the walls of some of the minute vessels which were probably at the junctions between the endothelial cells. These discontinuities let through not only plasma and fine particles of mercuric sulphide but also the much larger blood platelets. The plasma clotted outside the endothelial cells with the formation of fibrin, and the particles and the blood platelets were held up by the basement membrane.

In a similar way it appears that the increased permeability of small blood vessels during acute inflammation caused by mechanical trauma is due to the opening up of channels which are quite distinct from the vesicle system, and are probably between the cells. My colleague Marchesi has shown that colloidal carbon introduced into the blood stream of rats the mesenteries of which have been inflamed by a light stroke, escapes between the endothelial cells of the minute vessels in the injured area, and becomes for a time entrapped between the cells and the periendothelial tissues (Fig. 8).

Thus there is evidence to suggest that in normal vessels transport of fluid may be principally through the substance of the endothelial cells, but that in pathological conditions there may be an actual solution of continuity of the vessel wall, probably at the cell junctions, enabling much more fluid, as well as solid bodies, to pass through. This solution of continuity may be of a very labile nature, that is to say, the endothelial cells may part and join together again rapidly, but the overall effect is to allow a considerable leakage of plasma from the inside to the outside of the vessels.

The researches of the past nine or ten years have considerably increased our knowledge of the membrane through which exchanges of essential substances take place in those animals with a circulatory system. We are still far from understanding the precise behaviour of this complicated structure even under the simplest physiological conditions. What is clear is that mathematical concepts for explaining the transfer of water and large molecules through the walls of small blood vessels on mechanical principles will have to take cognisance of what is now known of their structure. The conceptions arrived at from the morphological and mathematical approaches have not yet been reconciled. Indeed, one may wonder whether the long-discarded view of Heidenhain, that lymph is secreted by the walls of the capillaries, may not have a grain of truth in it, for if the vesicle transport theory should be supported by further evidence, it may become necessary to postulate that work is done during the transport of material across the vessel walls, and this could be construed as secretion.

It is perhaps astonishing that we are still so unsure of the mechanism of the exchange of substances between the blood and tissues for, as Marshall Hall pointed out, the whole elaborate apparatus of heart and large blood vessels exists merely to subserve this exchange which takes place in the finest vessels.

Science is rarely advanced by what is known in current jargon as a 'break-through'. Rather does our increasing knowledge depend on the activity of thousands of our colleagues throughout the world who add small points to what will eventually become a splendid picture, much in the way that the Pointillistes built up their extremely beautiful canvases. What I have mentioned here are a few such points which it has taken three hundred years to place in the picture.

UNIVERSITY COLLEGE OF NORTH STAFFORDSHIRE

EXTENSION TO DEPARTMENT OF PHYSICS

THE new extension of the Physics Department of the University College of North Staffordshire, Keele, was officially opened on October 5, by Dr. F. A. Vick, director of the Atomic Energy Research Establishment, Harwell. This new extension represents a very considerable increase in the teaching facilities at Keele and the extra floor area that has been added to the Department amounts to some 18,000 sq. ft. Most of the space in this new extension is actually devoted to undergraduate and post-graduate teaching in the form of either lecture theatres, tutorial and colloquium rooms, or large teaching laboratories. Since the space that had been used in the old building for teaching has now been liberated for expansion of the Department's research activities, an increase for the latter has also been made possible, by the completion of this building.

The new building has a somewhat striking appearance (Fig. 1), and the main frontage is formed from vertical buttresses which are finished in large grey

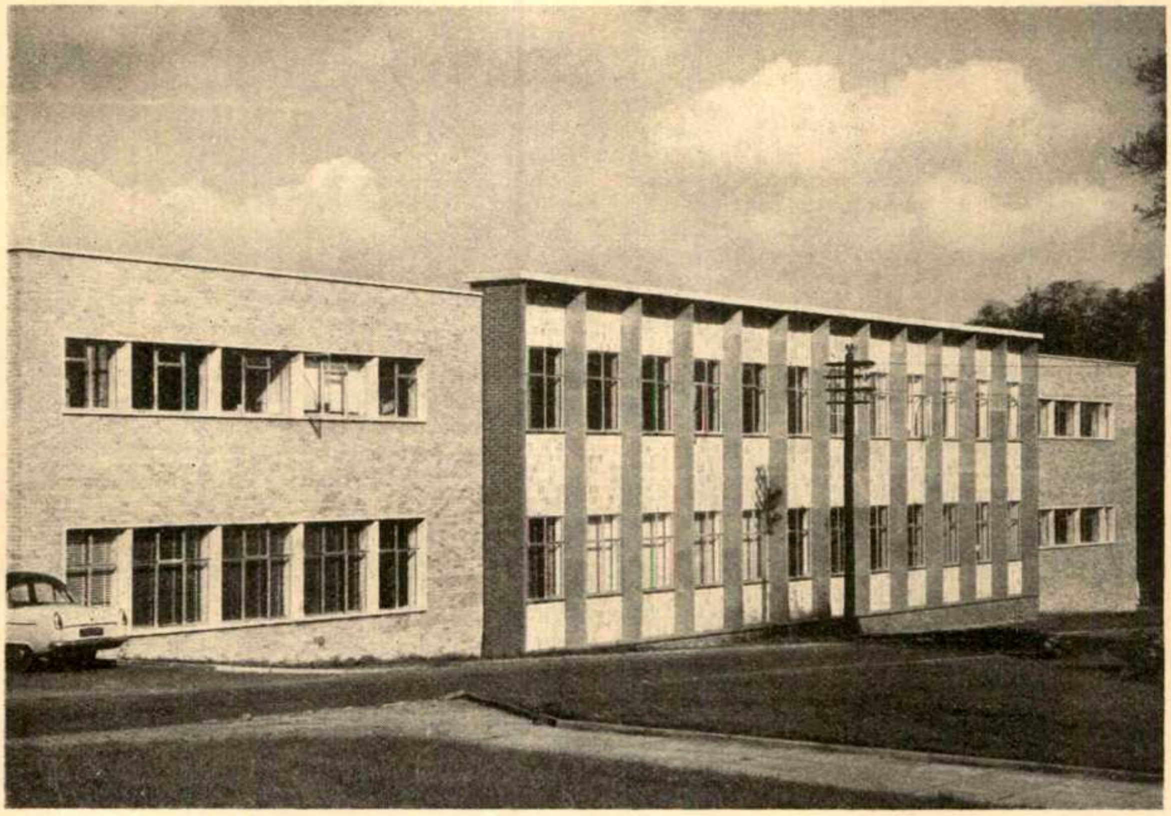

Fig. 1. New extension of the Physics Department, University College of North Staffordshire

slate slabs with inset walls of sparkling quartzite. The contrasting contours and colours provided by this southern frontage give a very pleasing impression when viewed in autumn sunlight. The building has two main floors, the ground floor being on the same level as the single-storey building which has previously housed the whole of the Department, and connects with it through a wide corridor with swing doors intervening. One somewhat unusual feature of the actual construction was the necessity of building the whole structure in five separate portions so as to meet the anti-subsidence conditions which affect the site. It is, in fact, extremely difficult to recognize these separate sections now that the building has been completed and an air of integrated cohesion exists throughout the Department, new and old buildings included. The central feature of the new wing is the large lecture theatre which is situated in the middle of the structure and continues through both floors. It has been designed not only to meet the needs of the expanding numbers in the physics courses themselves but also for the time being to house the whole of Keele's foundation year consisting of about 230 students. Corridor space has therefore been provided around the whole of this lecture theatre together with a large open entrance hall stretching up to the roof of the building itself. This has already proved of very great value as an assembly and discussion area for the large number of students that are now using the building. One feature of this hall which has produced considerable comment has been the overhead lighting, which consists of fluorescent tubes mounted within a covered glass structure which is opened to the sky through the roof. The resulting effect is almost identical during the day or night, since in daytime the sunlight itself is diffused through the whole structure over the entrance hall, while at night the fluorescent light is diffused in a very similar way and a very similar effect is obtained.

There are also two smaller lecture theatres as well as the main theatre, one which will hold up to 60 students and the other about 40. Together with these is a series of other teaching rooms, including a colloquium room for postgraduate seminars, a reading room for use by both undergraduate and research students, and a tutorial room for the tutorials which Keele still hopes to maintain as an essential part of its teaching system. The teaching laboratory accommodation consists of three large laboratories and one rather small optics laboratory serving the first honours year, since specialized teaching is still being carried out in the old building, including the teaching of optics in the second and third honours years. Two of the main teaching laboratories are arranged one above the other and are identical in size and design, each being 44 ft. long and 30 ft. wide, and are designed to provide sufficient accommodation for experimental work by up to 50 students. Each laboratory has a technician's service room leading from it, which contains all the rectifier and control equipment. The services in the teaching laboratories have been carefully kept around the walls and also fed to island frames in the centre of the room. The benches on which the experiments are performed are thus entirely flexible, and their location and assembly can be adjusted to the needs of the particular experiments that are being carried out. Electrical supplies are carried in continuous trunking with four standard types of outlet panels providing either 3-phase a.c., single-phase a.c., or d.c. voltages of various values. As well as these main teaching rooms the new wing also houses various staff rooms together with the secretarial offices and technicians' accommodation.

About 250 people attended the opening ceremony of the new extension, a large majority of these coming from outside the College, including not only representatives from other universities and teaching institutions but also various representatives of the education authorities, both locally and regionally, and also a large number from different industries and Government research stations throughout the country. Sir Alfred Owen, who is chairman of the University College Council, took the chair at the official opening ceremonies, and first called upon the new principal, Dr. H. M. Taylor, to introduce the guest of honour, Dr. F. A. Vick. In introducing Dr. Vick, Dr. Taylor referred to the rather incongruous position in which he found himself as introducing a speaker who was probably much better known to a large number of the audience than he had been to Dr. Taylor himself. He explained, however, that Dr. Vick's enthusiasm and interest in the more basic and liberal approach to the teaching of a scientist had already made its impact on Cambridge during his own time there, and he was thus already very much acquainted with Dr. Vick's thoughts and ideas if not so directly with Dr. Vick himself. The audience was indeed very fortunate in having as its main speaker not only the director of the Atomic Energy Research Establishment but also the ex-professor of physics at Keele himself.

In his own speech Dr. Vick outlined the history of the Physics Department during its eleven years existence, starting from the single room in Keele Hall and explaining that the first extension of the Department had consisted of the acquisition of two cupboards and half a room in the basement. The first main stages of the Physics Department building itself were built in 1951 and 1952, and Dr. Vick explained that they had been purposely designed for research uses as much as for teaching with the idea that the main teaching block should follow later. It was in fact this block itself that was now being opened, thus completing the steps in the original plan. Dr. Vick's historical summary was lightly sprinkled with amusing anecdotes which served to show that the major experiment at Keele in mixing the arts and sciences had often had its lighter moments. In discussing the expanding research activities of the Physics Department itself, he underlined the increasing interest of physicists in solid-state phenomena and gas discharges, and explained that Harwell itself was now much interested in these branches of the subject although it was true that they still did a little nuclear physics !

The official ceremony ended with a vote of thanks given by Prof. D. J. E. Ingram, the present professor of physics, who emphasized the very large part that Dr. Vick himself had played in the planning and design of the new physics building and said he felt sure that all who were present would agree that these efforts had produced both a highly efficient yet very handsome building. He also gave particular credit to the architects and contractors who had managed to design and build the structure at a cost of less than £100,000, which must be somewhere near a record in these days of rising building prices.

The new buildings, together with the old wing, which is now devoted almost exclusively to research, were then opened for general inspection for the rest of the afternoon and it was gratifying to see the large number of animated groups that sprang up discussing both research topics and laboratory design. Some of these design features arose from the particular circumstances at Keele, such as the anti-subsidence foundations and the heating which is entirely by inset panel radiators fed from the College boiler house. One other characteristic feature of the building was the large projection room behind the main theatre housing the ciné projector and other lantern equipment. This is a particularly useful feature for the foundation year lectures, when all types of teaching methods are being used by the different departments throughout the College.

One other very fortunate feature of the opening ceremony was that it had proved possible to bring the new building into operation just before the new academic session started, and all was in fact ready for the lectures and classes which were due to begin two days later. D. J. E. Ingram

FUR SEALS BREEDING IN THE FALKLAND ISLANDS DEPENDENCIES

By F. A. O'GORMAN

Falkland Islands Dependencies Survey, 4 Millbank, London, S.W.1

BETWEEN December 1957 and March 1958 a Falkland Islands Dependencies Survey party of geologists and surveyors visited Livingston Island in the South Shetlands. On January 14 twenty-seven fur seals (*Arctocephalus tropicalis* (Gray)) on Cape Shirreff on the north coast were found, and on February 1 a further fifteen near Start Point in the north-west corner. There was no evidence that breeding had occurred[1].

The following year a party, led by me, was organized to carry out a preliminary investigation of the South Shetland fur seals, and during this visit a breeding group was found on Cape Shirreff on January 30. On February 29, 1960, H.M.S. *Protector* visited the South Sandwich Islands and found breeding fur seals on the south-east coast of Visokoi Island[2,3].

These are the first records of fur seals in any of these islands since 1902 when the Swedish Antarctic Expedition found one animal on Nelson Island in the South Shetlands[4], and the first record of breeding since the last century.

The Falkland Islands Dependencies consist of the sector lying south of South America between longitudes 20° and 80° west, and include the Graham Land Peninsula and the Islands of South Georgia, South Sandwich, South Orkneys and South Shetlands. South Georgia and South Shetlands saw the greatest part of the fur-sealing operations of the early eighteenth century. The present status of the fur seal on South Georgia has been discussed by Bonner[5].

The discovery of the South Shetlands in 1819 by Smith was closely followed by intensive sealing.

James Weddell[6] in 1825 reported that, between 1820 and 1822, 320,000 fur seals were killed and the colonies were virtually exterminated. At Cape Shirreff alone, 95,000 seal skins were taken in the season of 1821 by five British crews[7]. More than ninety ships were engaged in sealing around the South Shetlands during this period[8].

After this period of abundance, small catches were obtained up to 1871 when the re-developing colonies were again devastated. Between 1871 and 1890 more than 35,000 seal skins were taken[8,9]. The last definite report of the fur seal was on Nelson Island, though Hamilton[10] gives an unsubstantiated report of Canadian sealers taking animals up to 1904. Between 1925 and 1951 *Discovery*, *Discovery II* and *William Scoresby*, the ships of the *Discovery* Committee, made extensive voyages in the Dependencies and visited the South Shetlands, the South Orkneys and South Sandwich Islands without finding any fur seals[11-15]. A small number of fur seals were, however, found on South Georgia[16,17].

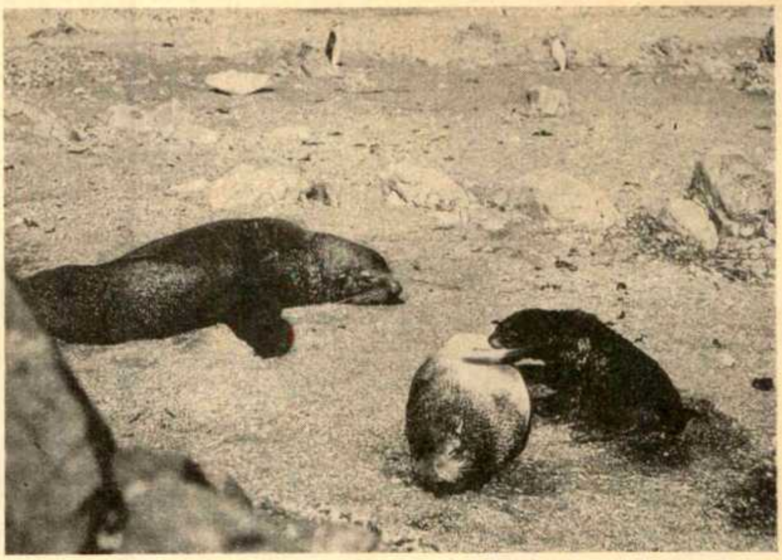

Fig. 1. Fur-seal family on Livingston Island, South Shetland Islands, February 2, 1959

In 1959 the Cape Shirreff colony, obviously at its earliest stage, consisted of one adult female and her male pup and seven adult males. A dead pup, also male, was found nearby. The seals were hauled out on a small windswept gravel beach frequented by groups of moulting elephant seals (*Mirounga leonina*), small numbers of Weddell seals (*Leptonychotes weddelli*) and numerous chinstrap (*Pygoscelis antarctica*) and gentoo penguins (*P. papua*), none of which had any apparent effect on the behaviour of the fur-seal group. The colony was watched intensively during January 31–February 4. On February 3 a second female, possibly the mother of the dead pup, arrived; no further change in the size of the colony occurred during this period. Some harem maintenance was being carried out by the dominant bull, but not very energetically. Quite often the female sparred and played with one or two of the younger males present, sometimes chasing each other in and out of the sea. The live pup measured 2 ft. 4 in. (71·1 cm.) in length and weighed approximately 15 lb. (6·8 kgm.) which, when compared with figures on the growth-rate in *Arctocephalus tropicalis* in South Georgia[18], would suggest that the pup was born about January 27. The pup was tagged with a monel metal cattle ear tag in the axilla of the right fore-flipper. On March 20 thirty-two fur seals were counted in the vicinity.

Unfortunately, it has not been possible to procure any further information on the subsequent development of this group, despite its considerable biological interest as one of the few mammal colonies where the natural growth could be studied from its inception.

The species has been identified, from a skull and skeleton, by Miss J. King of the British Museum (Natural History), as *Arctocephalus tropicalis gazella* (Peters, 1875); the same as that which occurs in South Georgia[19,20] and the South Orkneys.

The South Sandwich Islands, the most eastern islands of the Scotia Arc have never been renowned for fur seals. There are apparently no records of them having been laid waste in the 1820's as were those of the South Shetlands. Morrell, whose account of his voyages is generally discredited[21], found none in 1822, but Captain Buddington[9] states that in the 1875–76 season 2,000 were taken at the northernmost island (Zavodovski) and that, in 1876–77, 4,000 were taken by six vessels. In the following year the catch did not exceed 100. In 1880–81 no seals were found and in 1891–92 400 were obtained and a further 200 seen. Larsen visited several of the islands in 1908 but failed to find any[11]. These appear to be the only records of fur seals until the visit in 1960 of the Governor of the Falkland Islands, Sir Edwin Arrowsmith, on board H.M.S. *Protector* (Captain Forbes, R.N.). The only group of fur seals was found at the south-east corner of Visokoi Island on a beach which consisted of volcanic gravel and isolated outcrops of rock over which the seals sprawled. Sir Edwin Arrowsmith and Captain Forbes estimated the numbers to be in the region of 400. Photographs of the colony show a number of harem bulls and a loosely knit harem system. Several black pups can also be seen. None of the other islands in the group was visited. However, during January 7–11, 1961, the Falkland Islands Dependencies Survey vessel R.R.S. *Shackleton* visited the group to carry out geomagnetic observations, but only one fur seal was found on Visokoi Island and none was seen on the Islands of Zavodovski, Leskov, Candlemas, Vindication or Saunders. It must be emphasized that no special effort was made to locate fur seals. Though there were no skins or skulls collected from the South Sandwich fur seals, from their appearance they would seem to be similar to those of the South Shetland and South Georgia and are presumably the same species. Fur seals were also found on Clerke Rocks (55° 01′ S., 34° 41′ W.) on January 6 [22,23].

The discovery of these colonies and of the one on Powell Island in the South Orkneys in 1960 [24] demonstrates the rapid recolonization of this section of the Antarctic by the fur seals, with South Georgia presumably acting as the reservoir for this expansion.

Although no positive anatomical proof is available, it is reasonable to suppose that the fur seals of the South Shetland and the South Sandwich Islands (and

South Orkneys) present in the 1820's were also *Arctocephalus tropicalis*, and not *A. australis* as has been assumed until quite recently. Poland[25], in 1892, seems to have been in little doubt as to the differences between the species of fur seal on the Falkland Islands and the mainland of South America and those on South Georgia, South Sandwich and South Shetland Islands, his conclusions being based on the characteristics of the pelt. A fur seal upper canine tooth dug up from among remains of an early nineteenth century sealing camp on Livingston Island is not, unfortunately, referable to either species, but a more detailed search at this site might reveal material specifically identifiable.

It is hoped that these colonies, especially those in the South Shetlands will be strictly protected in keeping with the resolution on conservation in Antarctica passed by the Special Committee on Antarctic Research of the International Council of Scientific Unions[26], and allowed to re-inhabit the areas where they were once so numerous and so wantonly destroyed.

I wish to thank Sir Vivian Fuchs for permission to publish this article and Sir Edwin Arrowsmith and Captain David Forbes for the photograph and information on the South Sandwich Islands.

OBITUARIES

Mr. M. A. C. Hinton, F.R.S.

With the death on October 3 of Mr. Martin A. C. Hinton there passed one of the last great amateur naturalists of the Victorian era, whose contributions to geology and zoology earned him world-wide renown.

Martin Hinton was born in London on June 29, 1883, the eldest of three children. His formal education ended at the age of twelve when he left school to begin legal work in the City. His interests in natural history were already growing and he was a frequent visitor to the Museum of Practical Geology, then in Jermyn Street, where handling the collections and talking with the curators he rapidly acquired an extensive knowledge of the subject. After eleven years as a 'voluntary worker' at the British Museum (Natural History), he joined the staff as an assistant in the Zoological Department in 1921; he was made deputy keeper in 1927 and keeper in 1936, a post which he held until his retirement in 1945.

In 1899, when only sixteen years old, he read his first paper to the Geologists' Association on the Pleistocene deposits around Ilford and Wanstead. This was the beginning of a series of papers on the Pleistocene geology of the Thames valley which continued for a quarter of a century. He did pioneer work in recording sections in the Thames gravels, he collected and identified the fauna they contained and gave stimulating if sometimes unorthodox interpretations of the Pleistocene history. His views are summed up in a paper read to the Yorkshire Geological Society in 1926.

On joining the staff of the British Museum (Natural History), Hinton directed his attention to faunal studies, especially of rodents, in which group he made major contributions. His painstaking work on these small and difficult mammals includes taxonomic investigations on voles and lemmings, British fossil rodents and lagomorphs; he was early to see the potential use of rodents for stratigraphical correlation of Pleistocene deposits, a technique which has become increasingly valuable. But he was not to be limited to the dry bones of the Museum collections; he took a keen naturalist's interest in the living rodents, and his British Museum booklet on *Rats and Mice as the Enemies of Mankind* stresses cogently the immense destructive potential of these pests. In the 1930's Hinton was largely responsible for the success of the Ministry of Agriculture's campaign to exterminate the muskrat in Britain, which had at that time become a major hazard, breeding very rapidly and undermining river and canal banks and even gravel railway embankments.

At the opposite end of the size-range in mammals, Hinton devoted his attention to whales, contributing reports on antarctic whales for the Colonial Office and collecting a school of false-killer whales stranded on the Dornoch Firth; he clearly appreciated the importance of studying populations as opposed to individuals, and his salvage of 127 whales from a remote part of Scotland and transporting them to London was a triumph of organization and perseverance.

Hinton carried out a large measure of administrative duties both within the British Museum and in various learned societies; for some years he was an editor of the *Zoological Record*, and zoological secretary of the Linnean Society; he served on the councils and was a vice-president of both the Zoological Society and the Linnean Society. He was elected to fellowship of the Royal Society in 1934.

Hinton was by nature shy, but in the company of friends he was unsurpassed as a raconteur. He was blessed with robust health throughout life, and possessed a remarkably retentive memory, failing eyesight in later years virtually prevented him continuing with scientific pursuits His first wife, by whom he had three children, predeceased him, and shortly after his retirement he married Dr Dina Dobson and went to live in Somerset close to the Mendip Hills, where his early interests in Pleistocene cave faunas had grown He rarely went to London in later years, but all who visited him, professional or amateur, novice or doyen, were assured of a very warm reception, and the benefit of his sage advice.

R. J G. Savage

Dr. G. H Young

Dr. George H Young, whose sudden death on October 10, 1961, at the age of fifty-two is reported from Pittsburgh, was a chemist known principally in the United States for his work in the field of organic polymers, resinous coatings, corrosion protection and industrial and marine paints.

During the Second World War he was a specialist consultant on corrosion and protective coatings to the U S War and Navy Departments, as a result of which he became known internationally for some joint studies with Drs. Seagren and Zehner on the interaction with steel of anti-fouling paints and he received the U S Navy's Bureau of Ordnance Development Award in 1945

He served as secretary to the technical committees which initiated the war-time synthetic rubber programme and was continuously associated informally with this major U S. Government undertaking until its termination in 1955 He had been a special consultant to the Department of Defense and was a member of the National Research Council's Material Advisory Board He also served as technical consultant to the Pennsylvania General State Authority

Since 1951 Dr. Young had been a director of research at the Mellon Institute, where he had been active in many spheres of administration and consultation, as well as patent adviser to the Institute's scientific personnel, having been admitted to practice before the United States Patent Office in 1940

To his many activities Dr Young added membership of numerous scientific and technological societies, including some in Britain and Germany, and in 1949 he served as U S delegate to the United Nations Conference on the Conservation and Development of Natural Resources

O D Hunt

Prof. W. N. Bailey

Prof Wilfrid Norman Bailey, who died at Eastbourne on October 23, was born at Consett, County Durham, on September 5, 1893 He soon displayed his mathematical abilities, and after completing a brilliant undergraduate career at Trinity College, Cambridge, becoming a Wrangler in 1915, he resigned a Research Exhibition to take up war service During 1915–19 he was an instructor lieutenant in the Royal Navy in which capacity he witnessed the Battle of Jutland. In later years he looked back on this period of his life with a certain nostalgia. When war service was finished, he held a number of university appointments at Birmingham and Manchester, and in 1944 he was appointed to the chair of mathematics at Bedford College, University of London, from which he retired in 1958

Bailey's interest in mathematics was focused on the theory of hypergeometric series and Bessel functions, and on these topics he published some fifty papers in addition to the well-known Cambridge Tract which he wrote on *The Hypergeometric Series* During the whole of his life these subjects retained their fascination for him and he had, to an exceptional degree, the capacity for conveying his excitement to others He was normally of rather a placid demeanour, but it was a revelation to hear him lecture on any topic which had aroused his interest

Prof Bailey took a full part in the mathematical life of the country, and was at various times librarian, editor, secretary and vice-president of the London Mathematical Society. Although he found committee membership somewhat tedious, he always accepted any work of this nature which he felt it was his duty to undertake.

Prof Bailey is survived by a widow, a son and a daughter He will be remembered by those who knew him both for his intense enthusiasm for mathematics and for his genial sociability

H. G Eggleston

Dr. Marian W. Smith

Dr Marian W Smith (Mrs. H F Akehurst), honorary secretary of the Royal Anthropological Institute since 1956, died on May 2, after a long illness

Marian Wesley Smith was born on May 10, 1907, in New York, and gained her master's degree at Columbia University in 1934, proceeding to the doctorate in 1938 Between 1937 and 1947 she taught in a number of American universities, and held office in several learned societies, including the presidency of the American Ethnographic Society during 1944–45 During this period too she carried out extensive field work on the Indians of Washington State and British Columbia, resulting in monographs of the Pyallup-Nisqually (1940) and the archæology of the Columbia-Fraser River (1950) as well as a number of papers in learned journals She later did work in Pakistan, but owing to her untimely death this was never brought to the stage of publication

She was already known as a leading anthropologist, notable for the breadth of her view, when, in 1952, she married an Englishman, Mr H Farrant Akehurst, and made her home in Great Britain She undertook part-time teaching work at the London School of Economics, and in 1956 she accepted the honorary secretaryship of the Royal Anthropological Institute. It was this part of her work which made her known to and loved by practically all British anthropologists. She devoted a great deal of time to the affairs of the Institute, including a much-needed overhaul of its finances, which was carried out in close collaboration with the honorary treasurer, Sir George Beresford-Stooke, and helped by the magnificent generosity of Mrs. Brenda Seligman She initiated an excellent tradition by organizing a succession of symposia on subjects marginal to anthropology, namely, race problems, primitive music and the domestication of cattle, thereby making use of the specialized knowledge of many experts in other fields of investigation.

Her ability, her devotion to the Institute, and above all the warmth of her personality were such that every regular attendant at the meetings of the Institute will feel the loss of a personal friend

A. E. Mourant

NEWS and VIEWS

The Royal Society: Officers for 1962

AT the anniversary meeting of the Royal Society on November 30, Sir Howard Florey, professor of pathology in the University of Oxford, was re-elected president. The other officers re-elected for the ensuing year were: Treasurer, Lord Fleck, formerly chairman of Imperial Chemical Industries, Ltd.; Biological Secretary, Sir Lindor Brown, Waynflete professor of physiology in the University of Oxford; Physical Secretary, Sir William Hodge, Lowndean professor of astronomy and geometry in the University of Cambridge; and Foreign Secretary, Sir Patrick Linstead, rector of the Imperial College of Science and Technology. Other members of Council elected (or re-elected) were: Mr. F. C. Bawden, director of Rothamsted Experimental Station; Mr. E. J. H. Corner, reader in plant taxonomy in the University of Cambridge; Prof. J. E. Harris, professor of zoology in the University of Bristol; Sir Harold Himsworth, secretary, Medical Research Council, consulting physician to University College Hospital, London; Prof. A. F. Huxley, Jodrell professor of physiology at University College in the University of London; Sir Christopher Ingold, emeritus professor of chemistry at University College in the University of London; Prof. W. T. J. Morgan, deputy director of the Lister Institute and professor of biochemistry in the University of London; Prof. C. F. Powell, Melville Wills professor of physics in the University of Bristol; Prof. O. A. Saunders, professor of mechanical engineering at the Imperial College of Science and Technology in the University of London; Dr. C. J. Stubblefield, director of the Geological Survey of Great Britain and the Museum of Practical Geology; Sir Gordon Sutherland, director of the National Physical Laboratory; Sir Graham Sutton, director-general of the Meteorological Office; Dr. H. W. Thompson, reader in infra-red spectroscopy, University of Oxford; Prof. C. H. Waddington, professor of animal genetics in the University of Edinburgh; Prof. A. G. Walker, professor of pure mathematics in the University of Liverpool; Prof. F. C. Williams, professor of electrical engineering in the University of Manchester.

Psychology at Cardiff: Prof. G. Westby

MR. G. WESTBY, who has been appointed to be the first holder of the new chair of psychology in the University College of South Wales and Monmouthshire, is at present head of the Department of Psychology at Hull. He is well known by reason of his outstanding success in developing his present department during the past twelve years. Starting almost from scratch, its activities now include a large and flourishing honours school, the high standards of which are widely admired and a varied and enthusiastically pursued programme of research. The broad basis, coupled with the strong integration, of the Department have enabled it also to make a full contribution to interdisciplinary courses at the honours level and to the training of graduate students in the social sciences.

Mr. Westby, after reading the Honours School of Philosophy, Politics and Economics, acquired considerable experience in the education and treatment of maladjusted children before returning to Oxford after the War to gain a distinction in the diploma in psychology in 1946. Soon after he went to Hull it became apparent that he commanded the wide understanding of issues in the many diverse aspects presented by contemporary psychology, and the power to attract to his staff people of ability and initiative, without which all effort to build a living department must be in vain. These talents will find full scope at Cardiff, where exceptional possibilities exist, not only because of the keenness for a department of psychology among all the faculties concerned, but also by reason of the proximity and interest of the Welsh National School of Medicine. When difficulties inseparable from starting almost at the beginning have been surmounted, and the advantages exploited, we may confidently look forward to the establishment of a notable new centre of psychological studies.

Atlas Computer Laboratory, National Institute for Research in Nuclear Science: Dr. J. Howlett

DR. J. HOWLETT has been appointed head of the *Atlas* Computer Laboratory of the National Institute for Research in Nuclear Science. The appointment is effective from December 1. This Laboratory, to be built adjacent to the Institute's Rutherford High Energy Laboratory at Harwell, will house an *Atlas* electronic digital computer. Dr. Howlett, born in 1912, was educated at Stand Grammar School, Manchester, and the University of Manchester, where he read mathematics. Following an initial period in the Research Department of the London, Midland and Scottish Railway Co., Dr. Howlett joined the Ministry of Supply in 1940, where he was engaged in mathematical and computational work on a variety of defence problems. Since 1948 he has been head of the Computing Group of the Theoretical Physics Division at the Atomic Energy Research Establishment, Harwell.

Courtaulds, Ltd.: Appointments

SIR ALAN WILSON, a deputy chairman of Courtaulds, Ltd., has been appointed chairman of the company in succession to Sir John Hanbury-Williams who retires next summer. Sir Alan was elected to the Royal Society in 1942 in recognition of his work on the electronic theory of solids and on the properties of metals, and joined Courtaulds in 1945. Mr. C. F. Kearton and Mr. H. R. Mathys have been appointed deputy chairmen of Courtaulds. Mr. Kearton has been with the firm since 1946, and was elected to the Royal Society in 1961 for his work on the chemical engineering characteristics of volatile uranium products and technological developments in the textile industry. Mr. Mathys is a chartered patent agent and was in general practice until the outbreak of war in 1939; he joined Courtaulds in 1946 to take charge of the Patent Department at Coventry, and was appointed a director in 1954.

Nora: a New Zero Power Reactor in Norway

THE zero power reactor, *Nora*, of the Norwegian Atomic Energy Institute (IFA), which will serve in connexion with the joint research programme in reactor physics of the International Atomic Energy Agency (IAEA) and Norway, was inaugurated at

Kjeller, near Oslo, on November 29. *Nora*, intended for the establishment of various physics data of importance for the development of power reactors, has been so constructed as to be very flexible and to permit a wide range of experiments to be carried out with it. One of its important features is the supporting device for the fuel elements which permits the fuel lattices to be changed readily. The reactor will operate at a power-level of only a few watts. The financing of *Nora* was made possible by a grant of 350,000 dollars from the U.S. Atomic Energy Commission under the Atoms for Peace programme in addition to the funds contributed by the Government of Norway.

The programme aims at obtaining precise and widely applicable reactor physics data on cores with mixed and variable lattices moderated by light water, by heavy water and by mixed heavy and light water. In addition to the critical assembly *Nora* itself, Norway is making available two reactor cores, one consisting of natural uranium and the other of slightly enriched uranium. A third core, provided under the supply agreement between IAEA and the United States, consists of fuel enriched to 3 per cent in the radio-isotope uranium-235. This core was originally used in development work for the nuclear merchant ship *Savannah* and contains approximately 42 kgm. of uranium-235. This is the first lease of special nuclear material through the Agency to one of its Member States. The Joint Scientific Programme Committee which is to conduct the *Nora* research project is headed by Dr. Raja Ramanna (India). The other committee members are Mr. Olav R. Kåsa and Dr. Henrik Ager-Hanssen, both from IFA, and Dr. Pierre Balligand, deputy director-general, and Dr. Carlo Salvetti, director of the Division of Research and Laboratories, both of IAEA.

Diamond Jubilee of Trans-Atlantic Radio

On December 12, 1901, Guglielmo Marconi became the first to send a wireless signal across the Atlantic. This remarkable achievement with such primitive equipment marked the birth of world-wide communication. During the spring of 1900, Marconi had succeeded in sending reliable signals from St. Catherine's in the Isle of Wight to the Lizard in Cornwall, a distance of 186 miles. This encouraged his belief that by using larger aerials and far more powerful transmitters he would be able to achieve trans-Atlantic distances. Scientists were highly sceptical, many said it was impossible because of the curvature of the Earth. Marconi was determined to make the attempt and a transmitting station nearly one hundred times more powerful than any previously constructed was built at Poldhu, near Mullion, in Cornwall. Enormous aerials were erected at Poldhu and at Cape Cod in Massachusetts, but both were wrecked in severe gales. Another, less ambitious in design, was put up at Poldhu, while Marconi and his two assistants sailed to Newfoundland where, from the top of Signal Hill, a receiving aerial was hoisted, at the third attempt, by means of a kite. At 12.30 p.m. (Newfoundland time) on December 12, 1901, Marconi and his assistant, G. S. Kemp, using one of the primitive receivers of the period with a telephone earpiece, heard a faint succession of S's in Morse code. Signals from Poldhu, 2,200 miles away, had crossed the Atlantic.

To commemorate this historic achievement, a Special Exhibition will be displayed at the Science Museum, South Kensington, during December 13–January 25.

Research in Shipbuilding

In a written answer in the House of Commons on November 21, the Parliamentary Secretary for Science, Mr. Denzil Freeth, stated that the shipbuilding and marine engineering industries in Britain have set up an executive committee, with the encouragement of the Department of Scientific and Industrial Research, to form a new association for ship research, and the proposals agreed within the industries were to be announced. Discussions with the Department on constitutional matters were well advanced, and those on details on the final financial arrangements are to follow.

U.S. Research Activities in the Antarctic

The U.S. National Science Foundation has announced a further allocation of approximately 1,500,000 dollars for research work in the Antarctic. The largest single grant among the twenty-seven grants which this sum comprises is for the Antarctic Meteorological Research Program of the U.S. Weather Bureau. The total grant for this programme is now nearly 400,000 dollars. A further sum, exceeding 100,000 dollars, has been allocated to a series of meteorological rocket firings. These firings will reach heights up to 200,000 ft. to investigate winds and temperatures. There has previously been no systematic measurements of these elements in high southern latitudes. The firings will be co-ordinated with similar soundings in other parts of the world through the Meteorological Rocket Network, and the results will be correlated with world-wide stratospheric wind measurements. The U.S. Weather Bureau will also conduct an ice survey of antarctic waters with the assistance of U.S. Navy aircraft. This is intended to assist in the analysis of data to be received from projected polar satellites. A biologist from Ohio State University will carry out research while being based for sixteen months at the main U.S.S.R. base at Mirny. The main objective is to study invertebrate land animals and correlate the results with ecological studies which have been made at United States stations. This arrangement will continue the practice whereby the United States and U.S.S.R. exchange scientists at antarctic bases through agreements reached between the U.S. National Academy of Sciences and the Academy of Sciences of the U.S.S.R.

The Institute of Reprographic Technology

The Institute of Reprographic Technology was inaugurated at a reception held at St. Ermin's Hotel, Westminster, on November 23. The Institute will function as a professional body with entrance by examination, and its aims will be to increase the efficiency and technical ability of those practising the art of reprographic technology. This will be achieved by providing a forum for the exchange of ideas and a continuing programme for the dissemination of the scientific knowledge related to the profession. It is hoped that as the Institute grows regional organizations will be developed based on the industrial centres. Mr. Charles Hanrott has been elected chairman of the Institute. Further information can be obtained from the Honorary Press Officer, Institute of Reprographic Technology, 157 Victoria Street, London, S.W.1.

Impact of Science on Society

Impact of Science on Society, No. 3, 1961 (Vol. 11), includes several particularly interesting articles. An editorial note, "Mankind and Outer Space", and an article by Prof R Courant, "General Problems confronting Computing Centres", both stress the opportunities and the importance of international co-operation in these fields Dr G H O Burgess, of the Torry Research Station, reviews the contribution which fish technology can make to the food supply of the world and stresses the need for a much greater research effort and more attention to the dissemination of the results of research Dr G. Charlesworth, now head of the London Traffic Management Unit, Ministry of Transport, writing on "Science and the Road Traffic Problem", describes some of the contributions which research has made in this field, and the opportunities which the scientific study of roads and traffic presents both in the prevention of accidents and improving the efficiency of transport

Education and Training in France

In May 1960 nine members of the West Regional Group of the British Association for Commercial and Industrial Education paid a visit to France to study the French system of education and training with special reference to the needs of industry Their report contains a comprehensive description of the present system of education and training in France, as well as the changes in the system which will take place during the next few years as a result of legislation enacted in 1959 (Pp v+51 London British Association for Commercial and Industrial Education, 1961 10*s*) When reforms are completely integrated, all children will remain at school until sixteen years of age and selection for vocational training will commence well before the end of the normal school career A large section of the report is devoted to the various types of vocational institutions which exist, the certificates and diplomas awarded and educational practice in the vocational schools There is also a detailed description of education and training at the three main factories of the Renault Works

Television and School Teaching

In a booklet on schools television, the National Union of Teachers suggests that television should not be considered as a substitute for the teacher but as an addition to teaching aids already available (*Schools Television · a Discussion Document* Pp 18 London National Union of Teachers, 1961 1*s*), that if television is to be regarded as an integral part of the apparatus of education, it should be the responsibility of local education authorities to provide sets; and that particular attention should be directed to the need for the provision of more television sets in primary schools The booklet quotes some of the findings from the Union's inquiry on schools television among 111 schools, distributed over the areas of 71 local education authorities, and compares them with similar findings in the B B C report The National Union of Teachers welcomes the setting up by the B B C and commercial companies of special bodies with responsibility for the form and content of the schools programmes, and comments favourably on the "degree of independence of the parent body" which the Schools Broadcasting Department of the B B C and its counterparts in commercial television enjoy The booklet examines the constitution of these bodies, the scope of their work, the special role of the Union therein, and their relationships with the schools The pamphlet states that "the principal limitations of the television programme compared with the film are that it is not under the control of the teacher to the same extent either before, during or after showing, and that it has not the same resources of colour presentation" On the other hand, it points out that "television has a great impact on account of its immediacy" The booklet also touches on the general impact of television viewing on children and the special position of Wales with regard to television

The British Broadcasting Corporation

In the annual report and accounts of the British Broadcasting Corporation for 1960–61 it is recommended that the higher-frequency bands, Bands IV and V, should be used for television with a change of line standard from 405 to 625 lines, as proposed by the Postmaster-General's Television Advisory Committee, and that two of the four channels available in the higher-frequency bands should be allotted to the B B C One channel would be used for an entirely new programme service so that the B B C could give viewers a genuine choice of balanced alternative programmes, while a second channel would carry the existing Band I service, duplicated on the 625-line standard The B B C recommends that the channels in Band III, not at present allocated to either B B C or the Independent Television Authority, should be used to improve the coverage of existing services in areas not well served at present, and, in particular, to provide an improved and distinctive service for Wales The B B C is carrying on with its experimental work on colour television with the approval of the Post Office and with support from the radio industry The experiments will include test transmissions in colour on 625 lines in Bands IV and V, thus extending the work already done by the B B C in the experimental transmissions on 625 lines in black and white On sound broadcasting, the report states that there is need for an earlier start to the day's programmes a similar extension is needed at the other end of the day, after midnight, for late-night workers Over and above the provision of three programme services, the B B C sees the need and the opportunity now for a supplementary fourth service in the form of local sound broadcasting on very high frequencies

Licentiateships in Printing and Furniture

For some time both the printing and furniture industries, in association with the City and Guilds of London Institute, have been developing advanced courses at a level beyond the full technological certificate to meet specific requirements for high-level qualifications for which, at present, there are no recognized awards The Institute has announced recently a new award, the licentiateship of the City and Guilds of London Institute, intended to provide that kind of recognition in selected fields where such a need exists The Institute has approved two such fields, printing and furniture, and the awards will be known as the Licentiateship in Printing of the City and Guilds of London Institute and the Licentiateship in Furniture of the City and Guilds of London Institute Candidates for either award must have had at least five years approved industrial experience after completion of apprenticeship. In printing, a candidate will be required to have obtained one of the Institute's craft certificates, have obtained the full technological certificate and have passed the examination for advanced qualifications In furniture, a candidate must have obtained a craft course certificate, the full technological certificate and passes in two of the advanced courses

The Dunfermline Museum

The Dunfermline Museum was opened in June by Dr Douglas Allan, lately director of the Royal Scottish Museum, Edinburgh This new museum has been established by the Carnegie Dunfermline Trust and will serve as a local museum of natural history and folk material The collections came mainly from the old museum at Pittencrieff House, which has now been closed The conversion of a private house has provided two main galleries which have been equipped with modern 'shop window' cases One of the galleries is given over to a display of the birds and animals of West Fife in their natural habitats, and the other shows material relating to Dunfermline from the stone age to the present day A smaller room is devoted to linen, for many years the staple industry of Dunfermline

South Australian Museum

The *Records of the South Australian Museum*, **14**, No 1 (1961), maintains the high standard of this publication and includes papers on the Aboriginal hammer-stones of South Australia, Acarina fauna, Central Australian mammals, the stratigraphy and vertebrate fauna of the Tirari Desert, South Australia, and a report on the archæological excavation of the Noola rock shelter.

Experimental Alteration of the Speech-rate

It is known from the work of Dr Wilder Penfield and his associates in Montreal that speech may be arrested or otherwise disturbed by electrical stimulation of certain areas of the cerebral cortex. In a recent paper from the Neurosurgical Service of the Foch Hospital (Suresnes-Paris), entitled "Arrest of Acceleration of Speech evoked by Thalamic Stimulation in the Course of Stereotaxic Procedures for Parkinsonism" (*Brain*, **84**, 363, 1961), Dr G. Guiot and his collaborators have been able to show that striking changes in rate of speaking may be produced by thalamic stimulation in the course of stereotaxic operations for Parkinsonism Although arrest of speech is stated to be the more common phenomenon, striking acceleration in the speech-rate was noted in certain cases and changes also occurred in the strength and modulation of the voice The locus of stimulation is reported to be the ventrolateral nucleus of the thalamus Although these observations call for repetition on the more adequate scale, they would appear to throw an interesting light on the part played by subcortical mechanisms in the delivery and control of speech

Mineral Resources of Uganda

The important part played by geological surveys in the economic advancement of under-developed territories is brought to mind by a recent publication on *The Mineral Resources of Uganda* (Bulletin No. 4 Compiled and edited by Dr. J. W. Barnes Pp v+89+2 plates Entebbe: Geological Survey, 1961. Shs 25) During 1960 the mineral commodities exported from Uganda reached a record value of £3 5 million, equal to almost a quarter of the aggregate output since mining first began in 1927, and in addition industrial minerals exceeding £1 million in value were produced for local use, and cobalt concentrates valued at £1 million were stockpiled The principal products are blister copper and ores of tin, tungsten and beryllium, but within the next year there will be a large output of superphosphate (estimated at £325,000 per annum) for East African use and possibly of niobium ores for export Since the Geological Survey began drilling for water in 1931 some 3,000 producing boreholes have been completed, yielding water supplies that have supplanted the disease-laden and ephemeral surface sources on which much of the population used to depend In addition to reviewing resources now being exploited, the publication records various mineral potentialities of possible future interest, one of the more unusual of these being heavy water, which forms 8–12 per cent of the water in some volcanic lakes in the Ankole district. Although much of the country has still to be thoroughly prospected and, particularly in the north, to be mapped geologically, the report is a striking refutation of the view, once frequently voiced by Colonial administrators, that Geological Surveys are not revenue-producing departments

Chagas' Disease

Preliminary surveys on the incidence of Chagas' disease in the Matalaque region, Southern Peru, by Eleazar Cordova, have shown that housing conditions favour the development of *Triatoma infestans*, the only vector found in this zone Domiciliary infection shows a high incidence (89 02 per cent), the rate of trypanosome infection in triatomides being 51·28 per cent (41 97 per cent in bedrooms), a fact that suggests the almost certain existence of human cases of Chagas' disease. Domestic animals are frequently kept and raised within houses; such is the case, for example, of guinea pigs (84 per cent), where *T. cruzi* was found in 4 out of 32 specimens examined. Felix Naquira, Eleazar Cordova, Cesar Naquira and Enrique Rubin de Celis (*Bulletin Chileno de Parasitologia*, **16**, No 3, July–September 1961) have also carried out epidemiological surveys on Chagas' disease in the village of Matalaque (Tambo Valley, Southern Peru) The application of xenodiagnosis revealed an incidence of 34 67 per cent (43 out of 124 individuals surveyed) of *Trypanosoma cruzi* infection, whereas complement fixation procedures yielded 32·23 per cent positive cases (30 out of 93 individuals) Xenodiagnosis was also positive in four guinea pigs and one dog The results obtained with the two methods were not entirely concurrent.

Fellowships in Engineering Study and Fundamental Research in Plastics

Princeton University is offering a number of fellowships in engineering study and fundamental research in plastics leading to the M Sc and Ph D degrees, particularly suited to chemical, electrical and mechanical engineers, and to chemists and physicists Instruction covers basic theory and properties, and principles of evaluation, production, fabrication, design and application of materials, as well as the chemistry of plastics The programme includes lecture and laboratory classes, and contact with industrial plants representing various interests of the plastics industry Fellowships with stipends valued at 1,500 dollars–2,100 dollars are available to applicants holding a first degree in engineering or physical science from a recognized institution. Further information can be obtained from Prof. Louis F. Rahm, Plastics Laboratory, Princeton University, Princeton, N J.

The Manchester College of Science and Technology

The annual report of the Principal of the Manchester College of Science and Technology for 1960–61 gives an impressive picture of expansion, achieved and projected, which demonstrates how important a contribution the colleges of technology are making to Britain's scientific and technological strength. The number of students increased by 164 to 1,983, of whom 1,535 were studying for the B.Sc. (Tech.), 192 for the M.Sc. (Tech.) and 129 for the Ph.D.; 5,408 students were also enrolled for non-university courses, and of these only 333 were full time. The teaching staff now numbers 287. A list of research projects in progress during the year, arranged under Departments, appended to the report, gives an impressive picture of the research effort, and there is also a list of publications during the year by members of the staff. No information as to expenditure on research is included other than the statement that 9 per cent of the income of £1,580,523 was in support of research. Expenditure rose by £167,562 to £1,574,826. Students obtaining the B.Sc. (Tech.) with honours numbered 281, compared with 180 for the period 1959–60 and 96 for 1956–57; for B.Sc. (Tech.), ordinary, the corresponding figures are 178, 128 and 77; for M.Sc. (Tech.), 71, 59 and 33; for Ph.D., 25, 27 and 32; and for the postgraduate diploma, 22, 24 and 22.

University News.

Cambridge

Corpus Christi College is planning a graduate extension of the College at Leckhampton House, Cambridge. It is intended to provide public rooms, and accommodation for a few Fellows, in the existing house, and to house research students and other Fellows in a new building close by. With this additional accommodation the College will be able to increase the number of its active Fellows from 22 to 37 or more, and its research students from 40 to at least 60. Prof. H. C. Longuet-Higgins, professor of theoretical chemistry in the University, has been appointed warden.

Edinburgh

Dr. M. E. Davies has been appointed as lecturer in the Department of Veterinary Bacteriology, and B. F. Leek has been appointed as lecturer in the Department of Veterinary Physiology.

London

Dr. B. W. Lacey, reader in bacteriology in Westminster Medical School, has been appointed to a chair of bacteriology at that School. Mr. D. G. MacRae, reader in sociology in the London School of Economics and Political Science, has been appointed to the chair of sociology tenable at that School. Dr. E. A. Power, lecturer in mathematics in University College, has been appointed to the readership in applied mathematics tenable at that College. Mr. J. L. Stollery, lecturer in the Imperial College of Science and Technology, has been appointed to the readership in aeronautics tenable at that College. The title of professor of molecular spectroscopy has been conferred on Dr. A. G. Gaydon, honorary lecturer in the Imperial College of Science and Technology.

Prof. J. T. Randall, Wheatstone professor of physics at King's College since 1946, has been transferred by the University of London to the chair of biophysics at the College. The lease of premises in Drury Lane, W.C.2, some 40,000 sq. ft. in extent, has been acquired to house the new Department of Biophysics. After conversion, the premises will be known as the Wellcome Biophysics Laboratories in recognition of the grant of £120,000 made by the Wellcome Trust in 1960 towards the purchase of the lease. Prof. Randall will assume the directorship of the Laboratories on their completion in 1963. The new premises will also house the Medical Research Council's Biophysics Research Unit, which has been an integral and important part of the biophysics activities of King's College since 1947.

Massachusetts

A high-speed digital computer has been given to the Massachusetts Institute of Technology by the Digital Equipment Corporation of Maynard, Massachusetts. The computer is a "Programmed Data Processor", manufactured by the Digital Equipment Corporation, and will be used in teaching students the principles and operation of modern electronic data-processing equipment.

Rhodesia and Nyasaland

Dr. A. D. Kemp, senior lecturer in chemistry in the University College of Fort Hare, has been appointed lecturer in organic chemistry in the University College of Rhodesia and Nyasaland.

Announcements

Sir Douglas Logan, principal of the University of London, has been appointed vice-chairman of the Association of Universities of the British Commonwealth in succession to Sir Eric Ashby. The chairman for the year 1961–62 is Mr. K. J. Maidment, vice-chancellor of the University of Auckland, New Zealand, and the honorary treasurer of the Association is Prof. R. Ogilvie Buchanan, of the London School of Economics.

Dr. Randal M. Robertson has been appointed as associate director (research) of the National Science Foundation, Washington. Dr. Robertson has been assistant director for mathematical, physical and engineering sciences at the Foundation since July 1958, a post which now passes to Dr. Geoffrey Keller.

Mr. R. M. Arnold, until June of this year chief veterinary research officer in Tanganyika, has been appointed deputy head of the Wellcome Veterinary Research Station. Mr. Arnold became assistant veterinary investigation officer at Reading in 1942. Later he was appointed as veterinary investigation officer, Jamaica, and became deputy director of agriculture (veterinary and livestock) and superintendent of livestock services in that Colony.

The 1962 International Conference on "Precision Electromagnetic Measurements" (formerly Conference on "Standards and Electronic Measurements") will be held during August 14–16 at the Boulder Laboratories of the National Bureau of Standards, Boulder, Colorado. Further information can be obtained from Dr. James F. Brockman, National Bureau of Standards, Boulder, Colorado.

The International Society of Soil Science Joint Meeting will be held at Massey Agricultural College, New Zealand, during November 13–22, 1962, with pre-meeting tours during November 2–12 and post-meeting tours during November 23–December 1. The Joint Meeting is one of Commissions IV (Soil Fertility) and V (Pedology) of the International Society. Further information, together with an attractive brochure, can be obtained from the Secretary-General, P.O. Box 8001, Wellington, New Zealand.

THE TROPICAL PRODUCTS INSTITUTE

THE Tropical Products Institute of the Department of Scientific and Industrial Research held its first open days during October 19–20 when more than 500 people accepted invitations to be present. These included representatives of diplomatic missions; scientists from other Government institutions, universities and industry; representatives of commercial firms dealing in tropical products; and visitors from tropical countries. During the open days most of the laboratories were open to visitors and special displays were arranged to describe work in progress. This varied from the short-term advisory work to long-term research projects.

The Tropical Products Institute began as a part of the Scientific and Technical Department of the Imperial Institute and, therefore, has a history going back nearly seventy years. During most of the post-war years it was attached to the Colonial Office, but in 1959 was transferred to the Department of Scientific and Industrial Research, primarily in order that its services could continue to be available to Colonial territories after they had attained independence. In 1960 a total of nearly 1,000 inquiries was received from 62 Colonial, Commonwealth and foreign countries. These covered aspects of all the subjects on which specialists' advice is available at the Institute, including foods, fruits, essential oils, plant drugs, pesticides, oilseeds, fats, waxes, leather production, fibres, pulp and paper-making, board-making and solar energy. A comparatively new section at the Institute, the importance of which is growing considerably, is that dealing with inquiries on the economics of the production and marketing of tropical products; it also advises on suitable small industries for under-developed areas.

A research project with which the Institute has been concerned for many years is that of the pyrethrum industry in Kenya. Scientists at the Imperial Institute were instrumental in introducing this crop into Kenya in 1928 and it is now a very important export. One of the lines of work at present in progress is directed to improving the strains of the plant by breeding, and investigations are going on with Rothamsted Experimental Station to estimate the individual toxicities of the four esters responsible for the insecticidal activity of pyrethrum. These are separated by two-stage chromatography and sent to Rothamsted for testing. Another part of the Institute's work on pyrethrum is the investigation of the biosynthesis of pyrethrins in the plant. In particular, work has been directed at finding the site of synthesis and, for example, the effect of fertilization of the flower head. For this purpose acetic acid or mevalonic acid labelled with radioactive carbon is fed to the plant, the pyrethrins are isolated and, if radioactive, the site of labelling is determined. From this work it has been found that the synthesis occurs in the flower head and that fertilization of the flower does not influence the production of the insecticide.

One of the important projects in the Oils, Fats and Waxes Section has been an investigation into the factors which make Nigerian palm oil difficult to bleach. As a large part of the palm oil produced is used for margarine it is essential that it should be easily bleached to remove the reddish coloration which is normally present. Malayan palm oil has always been more easily bleached, and therefore has fetched a higher price, than palm oil from Nigeria. Work at the Institute has shown that the poor bleaching qualities of the Nigerian oil are due to the high initial carotene content and to oxidation caused by delays in processing which occur when primitive methods of collection and extraction are used. Oxidation by lipoxidase has been shown to take place when unsterilized and bruised fruit is left for long periods before extraction, and atmospheric oxidation during processing also takes place, usually due to iron contamination, where the iron acts as a catalyst. As in much of the Institute's work a fundamental chemical investigation has been followed by practical recommendations, and the small-scale producers of palm oil in Nigeria are now being encouraged to give more attention to the preparation and processing of the oil.

The accommodation at the Tropical Products Institute includes a pilot-plant laboratory which was on show to visitors during the open days. Here wax was being extracted from banana skins on a fairly large scale in a continuous process using about 7 l. of solvent. Heat is supplied by a steam-heated glass coil. The wax, which is removed by this method, constitutes 8–9 per cent by weight of the banana skin and may prove to be of use in the formulation of polishes. Investigations are also being carried out of the esters of a triterpenoid alcohol present in the wax. Also in the pilot plant laboratory are stills for the hundredweight-scale extraction of essential oils from bark, leaves and other plant materials. These provide very useful information for overseas growers who wish to produce these oils under larger-scale conditions.

In the Fibres Laboratory visitors were shown methods used for the physical testing of fibres, including a hybrid sisal which has been developed in Tanganyika. This has a much greater yield than the normal variety, and at the Institute the physical characteristics of the two types are being compared. Initial tests have shown that the hybrid gives a finer fibre and compares favourably in other respects with ordinary sisal. Other work in this Laboratory involves a study of the structure of fibres using methods similar to those used in electron microscopy. A cellulose acetate replica of the surface of a longitudinally cut fibre bundle is made, and this is metal-shadowed with chromium under high vacuum. The preparation is then examined using a light microscope and magnification of about 1,000.

The Pesticides Information Service of the Department of Technical Co-operation is also housed at the Tropical Products Institute and its work was shown to visitors during the open days. Much of the work in London is in providing information and abstracts, but there is also a laboratory where the control of bilharzia disease is being studied. This disease is caused by a parasitic worm and spread by various tropical snails. A colony of one of these, *Australorbis glabratus*, is maintained at the Institute so that promising chemicals can be tested as molluscicides.

Among the many other exhibits of work in progress, visitors were able to see types of building board made of waste materials such as groundnut shells, work on the formulation of insecticides for the malaria control campaign of the World Health Organization, the study of the flavouring constituents of pineapple using gas chromatography, and the analysis of the amino-acid content of animal feeding stuffs.

The open days gave many people an opportunity to see something of the wide range of scientific work which the Tropical Products Institute is doing on the renewable resources of the less-developed countries of the world, for producers and users alike.

B. R. SMITH

NEW INSTRUMENT ASSEMBLY WING OF THE CAMBRIDGE INSTRUMENT CO., LTD.

A NUMBER of scientists, industrialists, and well-known scientific and engineering journalists were among the 150 guests who attended a luncheon on October 23 to mark the opening of a new wing at the Cambridge Works of the Cambridge Instrument Co., Ltd. The guests were met by Dr. P. Dunsheath, chairman of the company's Board of Directors, and Mr. H. C. Pritchard, managing director, and the opening ceremony was performed by Sir Keith Joseph, M.P., Minister of State, Board of Trade.

After luncheon they toured the new wing, the Research Block which has been in use for two years, and Production Departments producing instruments for use in medicine and gas analysers for research and industry. In addition, a number of research projects and special displays of instruments made by the Company's two London factories were exhibited.

The new wing—which is 150 ft. long, 50 ft. wide and provides, on two floors, a working area of approximately 15,000 sq. ft.—is primarily intended to accommodate production departments for the final testing and assembling of instruments prior to dispatch. Immediately obvious features are the clean functional sweep of its two raised storeys, the ground-floor-level car-park and loading bay beneath, and the harmonious way it blends with the research laboratories, opened two years ago (see *Nature*, 184, 1364; 1959), to which it has been planned as a logical architectural extension, and to which one end is joined by connecting doors. The other end of the wing is connected to other works buildings and the loading bay by a link block containing stairs and toilet facilities.

Structurally, the reinforced concrete frame of the raised building rests on a solid concrete slab supported by two rows of circular columns along its length, over which the slab is cantilevered out about 8 ft. front and back. The second floor and roof are mounted on pre-cast pre-stressed concrete beams spanning the full width of the building, so that the floor areas of both storeys are uninterrupted by intermediate columns. Windows are double glazed and the infill panels below faced with golden buff bricks. Air supplied throughout the building is conditioned and filtered by plant contained in two penthouses on the roof. Essential services, ventilating and heating inlets, gas, compressed air, water, electrical supplies, telephones, etc., are laid in horizontal ducts running the full length of the building below the windows and, to reduce fire risks, all work benches are wired with mineral-insulated metal-sheathed conductors.

Two-thirds of the first-floor area, adjacent to the entrance hall, is used as Production Offices and the remainder is occupied by the Microanalyser Department. This Department is responsible for assembling and testing 'Microscan' X-ray analysers and for the production of sealed and flow-type proportional counters. It is also concerned with the commissioning and servicing of 'Microscans' and operates an advisory service, including the analysis of samples provided by prospective customers. Complete installations are assembled in specially designed cubicles, each of which is supplied with its own special services. Conditioned air supplied to this Department undergoes an additional degree of filtration in view of the need for absolute cleanliness during final assembly of a 'Microscan'.

The whole of the second floor is devoted to final assembling, wiring and testing of a wide range of galvanometric indicators, recorders and controllers. Here again a dust-free atmosphere, so necessary for the assembly of intricate precision instruments and components, is provided. The functional interior design with its modern décor makes the new building a pleasant and comfortable place in which to work.

The new wing is the latest illustration of the considerable

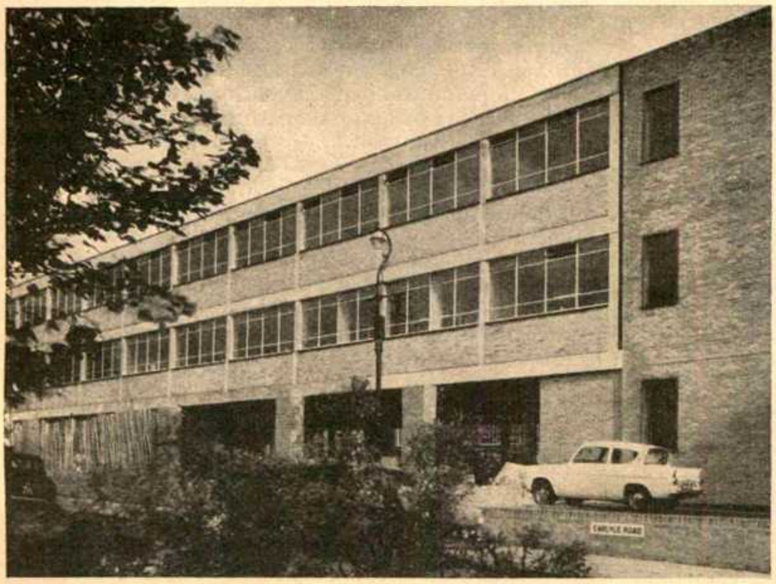

Fig. 1. Instrument assembly wing of the Cambridge Instrument Co., Ltd.

development of the Company in recent years and has been made necessary by the increasing numbers of new and improved instruments developed by the Research Department The building, which was designed by Edward D Mills and Partners, architects, was completed in less than a year by the contractors, J Jarvis and Sons, Ltd

J G HAMMOND

LIFE AND ITS ENVIRONMENT IN ANCIENT SEAS

DURING the British Association meeting at Norwich, the Geology and Zoology Sections (C and D) held a joint session on "Life and its Environment in Ancient Seas".

Prof C M Yonge, president of Section D, was in the chair and about 150 persons attended The programme was designed as a general session covering a wide range of palæoecological topics, but unfortunately the opening address by Prof Kaare Strøm (professor of limnology, University of Oslo), entitled, "In Quest of Ancient Seas", and the paper by Dr R H Cummings (Department of Geology, University of Glasgow) on the "Palæoecology of Foraminifera in Reef Limestones" were both cancelled, and so the scope of the meeting was more restricted than originally planned

The paper by Dr K A Joysey (Department of Zoology, University of Cambridge) on "The Life of Cephalopods in Ancient Seas" was a discussion of existing views on the mode of life of fossil forms, considered in the light of new information about living cephalopods Dr Anna Bidder (Department of Zoology, Cambridge) showed a series of excellent colour slides of the living *Nautilus* and gave an account of her observations, largely based on freshly captured specimens living in the aquarium at Noumea, New Caledonia The paper by Mr R W Sheldon and Dr F M Broadhurst (Department of Geology, University of Manchester) and Dr J G Potts (United Steel Companies, Ltd) on "Aspects of the Palæoecology of Marine Faunas in the Upper Carboniferous of the Southern Pennines", was a preliminary account of work still in progress seeking to elucidate the relationship between certain fossil faunas (mostly goniatites, lamellibranchs and brachiopods) and the petrology of the enclosing sediment Hence the session as a whole had an emphasis on molluscs, particularly cephalopods. Although unplanned, this bias came as a natural sequel to the molluscan theme of Prof. Yonge's presidential address

Many 'palæoecological' publications (including some by the present author), are merely records of association and distribution, and offer little interpretation of the relationship between the fauna and the environment The appreciation of a fossil biological system demands not only the reconstruction of the animals themselves but also of how they lived, what they did, their effects on other animals and on the environment. The Norwich session served well to illustrate this palæobiological approach to palæoecology

In surveying the problems of buoyancy control, Dr Joysey noted that the majority of living cephalopods are more dense than sea-water and support themselves by swimming, but *Sepia*, *Spirula* and *Nautilus* have a density near that of sea-water, owing to gas enclosed in rigid-walled chambers Unlike the swim-bladder of a fish, the volume of the cephalopod float is not affected by changes in pressure Hence, so long as some mechanism prevents the hydrostatic pressure from forcing liquid into the chambers through the porous siphuncular tube, changes in depth should not affect the buoyancy Denton and Gilpin-Brown have recently shown that *Sepia* can adjust its buoyancy by pumping liquid in and out of the chambers, like a submarine altering ballast This liquid has a lower salt concentration than the body fluids, and so osmotic pressure helps to counteract hydrostatic pressure Dr. Joysey observed that as *Spirula* and possibly *Nautilus* are recorded from depths below that at which an osmotic mechanism would fail, some other mechanism must be sought if the gas is to be maintained in the chambers An increase in the gas pressure would prevent liquid from flowing into the chambers and also prevent implosion of the shell, but any other mechanism whereby the siphuncular tube might become temporarily impermeable to liquid must be accompanied by a shell sufficiently strong to withstand the external pressure

Dr Bidder showed some photographs of *Nautilus* in a state of nearly neutral buoyancy swimming in mid-water or resting on the bottom, and others of it floating with part of the shell breaking the surface of the water She had also observed under-buoyant animals hanging by their tentacles, and had found that individual specimens could adjust their buoyancy

Dr Bidder stated that the gas in the chambers was not under pressure in a specimen just hauled from a depth of nearly 200 metres She had also extracted quantities of liquid from the gas chambers of *Nautilus* and using X-ray photographs she demonstrated that when a specimen had been turned upside down the shadows which were presumed to be bodies of liquid had indeed run to the opposite side of the chambers She found no evidence of living tissue in the gas chambers of *Nautilus*

In reviewing present-day interpretations of the posture of various fossil cephalopods, Dr Joysey noted that the position of the gas chambers in orthoconic shells at first sight suggested that they hovered vertically in the water, or rested on the sea-floor like church steeples Alternatively, if a load were present at the apical end, such as liquid in the apical chambers, they could have adopted a horizontal posture It is generally accepted that, in some forms, this apical counterbalance was provided by solid deposits within the siphuncular tube. Other forms have deposits within the apical gas chambers, but there has been some controversy as to whether these were laid down by a cameral mantle or whether they are post-mortem mineral infillings In view of the recent findings on living forms, Dr Joysey suggested that serious consideration should be given to the possibility that these deposits might have been precipitated during life from solutions transported through the walls of the siphuncular tube

By analogy with orthoconic nautiloids, Dr. Joysey pointed out that one of the functions of the belemnite guard was to act as a counterbalance. It lay at the posterior end of the main gas chambers while the bulk of the animal was at the anterior end, so giving a 'see-saw' type of stability. The morphological series from the belemnite to *Sepia* is well known. Functionally, this change involved sliding the body mass under the gas chambers, giving an 'air-ship' type of stability. In consequence, the counterbalance was progressively reduced and hence the volume of gas required to provide support could also be reduced.

Dr. Joysey referred to some palæozoic nautiloids (for example, *Ascoceras*) in which the juvenile was orthoconic, but by the development of highly oblique septa the adult achieved a horizontal posture, without resort to a counterbalance. Coiling of the shell produces a similar result as the body chamber comes to lie more or less horizontally below the float. Dr. Joysey briefly described Trueman's elegant investigation on the buoyancy and posture of ammonites. Trueman showed that an uncoiled form such as *Lytocrioceras* possessed greater stability than its tightly coiled counterpart. In functional terms such a shell has achieved the 'air-ship' type of stability, independently attained in such distantly related forms as *Ascoceras* and *Sepia*.

Dr. Bidder stated that *Nautilus* appears somewhat clumsy in side view but when seen from above, below or behind, its outline is remarkably streamlined. Its movement is slow in the encumbered environment of the aquarium, but more rapid in open water. Although it frequently swam near the bottom of the aquarium with its tentacles 'searching' the substratum, it had never been observed to crawl. Some of the photographs clearly showed the remarkable flexibility of the tip of the funnel, which can send the jet in almost any direction, thus giving considerable manœuvrability.

Dr. Bidder stated that the density of the body of *Nautilus* appears to be somewhat lower than Trueman's calculated value, and she suggested that it might prove necessary to modify his conclusion that the majority of ammonites were under-buoyant. Furthermore, his interpretations of the posture of ammonites are amenable to modification if the chambers contained unequally distributed fluid ballast.

Dr. Broadhurst outlined the work of Dr. J. G. Potts on the *Gastrioceras cancellatum* marine band near the top of the Millstone Grit Series, the work of Mr. R. W. Sheldon on another marine band in the Edale Shales towards the base of the Millstone Grit, and his own work in the Coal Measures.

In Dr. Pott's marine band some of the goniatites are preserved flat on their sides, whereas others are crushed in a vertical position, just as they settled on the sea-floor, leaving impressions of the venter on the bedding planes. It was suggested that a high proportion of vertically preserved goniatites probably indicated quiet conditions, and this was found to be at a maximum near the middle of the band, where the goniatites themselves were most abundant. The lamellibranchs had two periods of abundance, one above and the other below the goniatite maximum. The grain size and the amount of coarse detritus both had high values at the top and the bottom of the band, prior to the first and after the second lamellibranch peak. The marine band as a whole was described as a 'palæontological sandwich', the goniatites being the filling, the lamellibranchs the butter, and the coarse detritus the bread. It appeared that the absence of fauna in the sediments above and below the marine band could be attributed to turbulence and the greater rate of terrigenous sedimentation.

Mr. Sheldon's band contained fewer goniatites and lamellibranchs but abundant brachiopods. The amount of detrital material was low, most of the sediment being ankerite and silica. The brachiopods *Chonetes* and *Martinia*, the goniatite *Eumorphoceras* and the gasteropods in the fauna were abundant in the upper and lower parts of the band and sparse in the middle, analogous in pattern to the lamellibranch distribution present in Dr. Pott's marine band. In contrast the brachiopod *Productus* was abundant near the middle of the band and diminished upwards and downwards, this pattern corresponding with the abundance of ankerite.

Dr. Broadhurst was largely concerned with the conditions of sedimentation between marine bands. He showed photographs of a tree-cast 38 ft. high, standing vertically in non-marine sediments, its base rooted above a coal seam and its top in mudstone. He stressed that vertical preservation is not to be regarded as a freak occurrence, for he has records of many such trees at several horizons. Such preservation can only be interpreted as indicative of rapid sedimentation and it is significant in this respect that these vertical trees never cut through marine bands. Viewing their work as a whole Dr. Broadhurst suggested that a slow rate of deposition of terrigenous material appears to have been an important controlling factor during the deposition of the relatively thin marine bands, whereas more rapid sedimentation appears to have characterized the thicker intervening beds.

In the discussion which followed the papers Dr. Broadhurst and his colleagues indicated that the onset and the ending of marine band conditions were transitional rather than abrupt. Lateral changes could be detected at some horizons, for some *Lingula* beds pass laterally into true marine bands in other regions.

Dr. Joysey agreed that partially uncoiled ammonites like *Lytocrioceras* must have adopted different postures at various stages during growth, and commented that these might reflect changes in its feeding requirements. He noted that it was widely stated in the palæontological literature that *Nautilus* could adjust its buoyancy by moving in or out of its shell. Changes in shape of the body mass, however, would not affect its volume and so the density of the body would remain constant. Assuming that any space vacated within the body chamber would be filled with sea-water, then movements of the body would not affect its overall density. It appeared to him that this mechanism could not produce changes in density unless there was an unsealed gas bubble within the body chamber. Dr. Bidder stated that there was no gas bubble between the animal and the last septum, and that although small bubbles were sometimes present in the mantle cavity, these could be attributed to the aquarium aeration system.

The session as a whole provided useful liaison between geologist and zoologist, and each was able to gain a greater appreciation of some of the practical difficulties faced by the other in obtaining sufficient information to give an unequivocal answer to an apparently simple question. It also served to illustrate that one class of animals alone could provide abundant material for discussion, and that there remained plenty of scope for future joint sessions.

K. A. JOYSEY

THIRD AUSTRALIAN SPECTROSCOPY CONFERENCE

THE third Australian Spectroscopy Conference was held in the School of Chemistry at the University of Sydney during August 22–24 under the sponsorship of the Australian Academy of Science Spectroscopy Committee. A varied and interesting programme, consisting of 5 invited review papers and 51 research papers, was provided for the 227 participants. In addition, six exhibitors displayed some of the latest developments in spectroscopic equipment. The papers were arranged into sessions on vibrational, theoretical, molecular electronic and resonance spectroscopy with some parallel sessions concerned with instruments and analytical applications, including atomic absorption spectroscopy. After Prof R J W Le Fèvre had briefly welcomed the participants of the Conference to the School of Chemistry, Prof N S Bayliss officially opened the proceedings on behalf of the Australian Academy of Science and welcomed to the conference the overseas guests, Prof W C Price (King's College, London) and Mr J E Allan (Rukuhia Soil Research Station, Hamilton, New Zealand).

The conference opened with a session on vibrational spectroscopy, and Prof W C Price commenced with a stimulating review of recent developments in the far infra-red. After briefly referring to the experimental difficulties associated with investigations in the range 1–500 cm^{-1}, he then proceeded to discuss the selection of sources, dispersing materials and detectors, and concluded by giving examples of the use of this region to obtain information on rotational energy-level in gases, lattice vibrations in crystalline and molecular crystals, and impurity energy-levels in semi-conductors.

Three research papers then followed dealing with infra-red studies on hydrogen bonding. Prof A N Hambly (Department of Chemistry, School of General Studies, Australian National University) discussed the infra-red evidence for hydrogen-bonding in amino-sulphones, and concluded that stronger interaction occurs between the amino and sulphone groups on adjacent carbon atoms than occurs in the corresponding nitro-amines. This was attributed to the difference in the geometry of the interacting groups. Mr P. E Rogasch (Weapons Research Establishment, Salisbury) produced evidence to show that proton transfer can occur in systems that are strongly hydrogen-bonded. Mr I H Reece and Prof R L Werner (Department of Physical Chemistry, University of New South Wales) dealt with the intermolecular interaction between carbonyl and hydroxyl groups in solution, and showed how this interaction can be used to deduce *pKa* values for the hydroxyl compounds from the infra-red spectrum.

The session continued with papers on analysis of the vibrational spectrum on mono-methyl-arsine (Dr V Cranmer, Imperial Chemical Industries, Australia and New Zealand, Ltd , Central Research Laboratories, Ascot Vale), of dichlorofluoromethane-sulphenyl chloride (Dr N S Ham, Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) and tri-methyl borate (Prof R L Werner, Department of Physical Chemistry, University of New South Wales). Dr E Spinner (Department of Medical Chemistry, Australian National University, Canberra) discussed the vibrational spectra and structures of the hydrochlorides of the aminopyridines. The Raman and infra-red spectra suggest that whereas the positive charge resides on the ring nitrogen in 3-aminopyridine it is located on the amino-nitrogen in 2- and 4-aminopyridine. Mr R H Laby and Dr D J Greenland (Waite Agricultural Research Institute, University of Adelaide) were concerned with the implications of the infra-red spectra of molecules of amino-acids, simple peptides, alcohols and glycols adsorbed by montmorillonite. Methods for increasing the discrimination between similar infra-red spectra were described by Dr J Tregellas-Williams (Defence Standards Laboratories, Maribyrnong). Progress being made in the development of improved micro-wave-powered Raman sources was summarized by Dr N S Ham and Dr A Walsh (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization). The session on vibrational spectroscopy was concluded with a paper by Dr P Marmet (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) dealing with the problem of producing mono-energetic electrons in a mass-spectrometer and their use in obtaining details of the vibrational structure in the energy states of simple molecular ions.

Dr N S Ham (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization), in the session on theoretical and molecular electronic spectroscopy, reviewed some theoretical and experimental aspects of the Jahn–Teller theorem. He pointed out how the experimental manifestations of the theorem depended on the magnitude of the distorting forces. Examples showing orbital and/or spin degenerate ground and excited states were discussed. Mr E F. McCoy and Dr I G Ross (Department of Physical Chemistry, University of Sydney) considered the change of shape in electronic transitions of polycyclic aromatic hydrocarbons. They showed that encouraging agreement is obtained with experiment if calculations of the overall width and intensity distribution in the corresponding emission or absorption spectrum are based on the sum of the squares of the bond-length changes that accompany the electronic transition. Mr J C Mackie and Dr L E Lyons, from the same department, outlined theoretical methods which enable the accurate calculation of the ionization potential of a molecular crystal from a knowledge of the ionization potential of the free molecule, its polarizability and the crystal structure. Prof W. C Price discussed the ionization potentials of some simple radicals and molecules in terms of their electronic structure. It was shown that the π electron orbitals of the halogen substituted CH_3, CH_2 and CH radicals account for the magnitudes of the observed ionization potential and stability of parent molecules and ions. The effects of progressive substitution on the ionization potential of ethylene were also explained.

Dr E G McRae spoke on the theoretical relationship between fluorescence and vibrational structure and Davydov splitting in molecular crystals. Application of his theoretical treatment to the available information on the crystal fluorescence spectrum of anthracene leads to a prediction of a Davydov splitting of the order of 500 cm $^{-1}$ It is interesting to compare this with a later paper in the conference in which Mr A. R. Lacey and Dr L E Lyons (Department of Physical Chemistry, University of Sydney) described experimental investigations of the Davydov splitting in the spectrum of anthracene crystals which yielded an estimate of ~ 330 cm $^{-1}$ for this splitting, the much lower values (0–60 cm $^{-1}$) usually reported are attributed to the combined effect of incomplete polarization of the incident radiation and the thickness of the crystals used by other investigators

Mr M Batley and Dr L E Lyons (Department of Physical Chemistry, University of Sydney) discussed refinements in the quantitative prediction of the crystal spectrum of phthalocyanine In a paper by Dr E. A Magnusson and Dr H Shull (Australian Missionary College, Cooranbong) it was suggested that the barrier to internal rotation about a single bond may be explained both with regard to height and sense, in terms of interactions between the electrons in the terminal bonds and also to the possibility that the distribution of the electrons in the single bond itself is not cylindrically symmetrical Mr G L White (Defence Standards Laboratories, Maribyrnong) presented a theoretical paper on polarization in Raman spectra Dr A D Buckingham (Chemistry Department, Harvard) spoke on spectroscopy with polarized radiation He discussed the existing methods of determining the direction of the transition dipole moment with respect to molecular axes and outlined a new approach involving the measurement of the Kerr constant through absorption bands.

A review by Dr. I G Ross (Department of Physical Chemistry, University of Sydney) on optical masers preceded the session on molecular electronic spectroscopy After explaining the basic principles of optical masers, Dr Ross considered some of the general and research applications possible for the monochromatic high-intensity beams that can be produced Dr T M Spotswood (Division of Coal Research, Commonwealth Scientific and Industrial Research Organization) presented evidence for the formation of charge transfer complexes during the bromination of forms of carbon known to contain relatively high proportions of aromatic structures The existence of charge-transfer complexes between brominated polycyclic hydrocarbons and halogens in solution was also established, and the spectra of these were compared with those for the corresponding complexes for the corresponding unsubstituted hydrocarbons In a contribution from Dr A. V Bree (University College, London) the fluorescence and absorption spectra in the near ultra-violet of crystals of 9,10-dichloroanthracene, measured at room temperature, were discussed and shown to confirm that the corresponding transition in crystalline anthracene is short-axis polarized Dr Bree showed that photo-produced impurities accounted for fluorescence and photo conductivity observations In another paper from the same department, Dr T M Dunn presented the results of a rotational analysis of the 2700 Å system of *para*-difluorobenzene which confirm that a $B_{3u} \leftarrow A_g$ transition (polarized along short axis, that is, in plane of benzene ring and perpendicular to F–F direction) is responsible

Three papers from the Weapons Research Establishment, Salisbury, were concerned with investigations of the character of the emission associated with various electronic transition processes in flames and in the upper atmosphere Dr C L Cook and Mr J A McFarlane described the spectral characteristics of the emission from an ammonia/bromine pentafluoride diffusion flame Mr L J Drummond and Mr P E Rogasch did the same for the active nitrogen–chloroform and active nitrogen–methylene chloride flames Dr J C Burns outlined some of the difficulties associated with attempts to measure temperatures from the AlO-radical emission which accompanies the re-entry of the main body of a rocket research vehicle into Earth's atmosphere Vibrational equilibrium appears to exist and temperatures in the range 1,600°–2,000° K were obtained

During the session on analytical applications on emission spectroscopy Mr L S Dale and Mr R N Whittem (Australian Atomic Energy Commission Research Establishment) described the spectrographic techniques in use in health surveys of beryllium contamination In a second paper, Mr Whittem discussed the spectrochemical analysis of toxic and α-active materials. Mr A B Timms (Australian Mineral Development Laboratories, Adelaide) spoke on the spectrographic determination of hafnium/zirconium ratios Mr J M Nobbs (Defence Standards Laboratories, Finsbury) presented evidence to show that while the input of electrical energy to an arc gap between metal electrodes can be controlled to within very fine limits, the output of radiation from the arc column varies randomly from pulse to pulse by factors as large as 200, and is caused primarily by fluctuations in the evaporation of electrode material The theory of the photographic characteristic and its use in plate calibration formed the subject of a paper by Mr C Candler (South Australian Institute of Technology) The analysis of lubricating oils for the additive elements barium, phosphorus, calcium and zinc with a direct-reading spectrograph was outlined by Dr. R A. Cummins (Defence Standards Laboratories, Maribyrnong) Mr I Collison and Mr T Scott (Broken Hill Pty , Newcastle, N S W) spoke on their experiences with the calibration of an A R L. 'Quantovac' for the analysis of sulphur and phosphorus in carbon and low alloy steels

In a session on instruments and techniques the following papers were presented Mr J J McNeill (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) discussed factors influencing the design of an inexpensive general-purpose monochromator for use above 2000 Å The construction and performance of an Ebert scanning spectrometer was discussed by Dr S C Baker (Physics Department, Newcastle University College, N S W) A photoelectric device to prevent slow image shifts during long exposures in a high-resolution échelle spectrograph was described by Dr G R. Hercus (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) Outstanding problems of instrumentation in the development of the full potentials of X-ray fluorescence spectroscopy as an analytical tool were briefly considered by Mr J E Maloney (Philips Electrical Industries, Sydney) Mr J F Horwood and Mr D A Forss (Dairy Research Section, Commonwealth Scientific and Industrial Research Organization) described methods used for handling micro-quantities of samples for absorption spectrometry Mr F B. Wunderlich (John Lysaght Pty , Ltd , Newcastle, N S W) indicated how low-resolution infra-red spectra could be used for the identification of constituents in paints and plastics Mr A T Martin (C S R Chemicals, Rhodes) spoke on the reflectance of opaque materials as a function of pigment concentration Finally, Dr N Kelso King (Division of Physical Chemistry, Commonwealth Scientific and Industrial Research Organization) discussed the significance of isosbestic points in studying reaction mechanisms

The session on atomic absorption spectroscopy, which was held on the final morning, proved to be one of the most successful sessions of the conference It was very gratifying to witness the obvious intense interest in this subject, which was pioneered in Australia and New Zealand Mr J E Allan (Rukuhia Soil Research Station, New Zealand) opened this session by reviewing recent developments in the technique The progress made since the second Australian Spectroscopy Conference in 1959 was amply illustrated by the increase in published research papers from 5 to 50 at present Dr B G Davey (School of Agriculture, University of Sydney) described the application of atomic absorption spectroscopy to the analysis of agricultural materials It is now possible to determine rapidly many elements in soil and plant material, up to 170 samples an hour can be analysed for one element with a coefficient of variation less than ± 5 per cent using very simple equipment Mr D J David (Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization) discussed the determination of molybdenum by atomic absorption Molybdenum is believed to be present in a flame as the oxide under normal conditions, but in an acetylene–air flame operated under reducing conditions the molybdenum trioxide dissociates to atomic molybdenum which can be detected by absorption Mr David suggested that compound formation under flame conditions may account for many of the interferences that can occur in analysis by atomic absorption The research in atomic absorption being carried out at present at the Rukuhia Soil Research Station was surveyed by Mr J E Allan Extension of the range of elements accessible to the technique by the use of nitrous oxide–acetylene flames is being investigated. The determination of cobalt and nickel in agricultural materials has been studied in detail, and procedures established for the analysis of fertilizers Dr J B Willis (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) showed how atomic absorption was being used to determine traces of heavy metals such as lead, mercury, bismuth, nickel, cadmium and zinc in biological materials. The sample preparation procedures are much simpler than those involved in most existing methods, cadmium and zinc can be determined directly in urine and preliminary experiments suggest that zinc may be determined in blood serum and whole blood by spraying the diluted material directly into the flame Cathodic sputtering appears to be an attractive method for atomizing those elements (for example, aluminium, strontium and titanium) which form refractory compounds under flame conditions, and Drs B M Gatehouse, J V Sullivan and A Walsh (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) discussed the factors affecting the cathodic sputtering of various metals. In some instances it has been possible to establish sputtering conditions which permit analytical determinations, but the method is still unsatisfactory for aluminium.

The final session of the conference was devoted to resonance spectroscopy Dr G S Bogle (Division of Physics, Commonwealth Scientific and Industrial Research Organization) reviewed the development of the theory of electron paramagnetic resonance Mr A J Harle, Dr. L E Lyons and Mr B K Selinger (Department of Physical Chemistry, University of Sydney) summarized the results of a preliminary survey of the electron-spin resonance spectra of some charge-transfer complexes between chloranil and aluminium oxide, hexamethyl benzene and tetracyanoethylene, dibenzacridine and tetracyanoethylene or chloranil Dr G S Bogle (Division of Physics, Commonwealth Scientific and Industrial Research Organization), Drs W F Forbes and W E Savige (Division of Protein Chemistry, Commonwealth Scientific and Industrial Research Organization) reported some investigations of the electron paramagnetic resonance properties of cystine and related compounds after irradiation with mercury 2537 Å. radiation and a sun-lamp (peak ~ 3100 Å) Similar spectra are obtained for all the compounds examined, indicating that the same trapped free radical RS ($R = \mathrm{CH_3\,\underset{|}{CH}\,(NH)_2{\cdot}COOH}$) is formed in each case on irradiation Mr. T. J Seed (Department of Physics, University of Canterbury) discussed the paramagnetic spectra of manganous ions in undiluted crystals of the solid-solution ammonium chloride–manganous chloride–water.

In the final paper of the conference Dr C K Coogan (Division of Chemical Physics) and Prof H S Gutowsky (Chemistry Department, University of Illinois) reported on nuclear magnetic resonance in sodium hydrosulphide Observations on the hydrogen-1 and sodium-23 resonances in polycrystalline samples of sodium hydrosulphide tend to confirm Pauling's hypothesis that the hydrosulphide ion is tumbling very rapidly in the crystal lattice and thus presents an outward spherical form to the surrounding ions This occurs above 80° C, and it was also observed that SH⁻ ions can diffuse through the lattice

R A Durie

COLLOIDAL SYSTEMS

An informal discussion on colloids, under the auspices of the Faraday Society, was held in the Royal College of Science and Technology, Glasgow, on June 27 The meeting was held to mark the centenary of the appearance of Thomas Graham's paper, "Liquid Diffusion applied to Analysis", in which a clear definition of colloids and crystalloids was first given An attempt was made to cover as many colloidal topics as possible, in the event, this did not prove feasible and the subjects tended to be somewhat biased towards association colloids About seventy people attended the meeting, including several from Holland

The chairman, for the morning session, was Prof P L Pauson, who welcomed the visitors to the Royal College and indicated the reasons for holding the discussion at this time and place (Graham held his first chair at the College) The first speaker was Dr A J Hyde (Glasgow), who gave a brief biography of Graham with rather greater emphasis on the private and non-scientific side of his life than on his scientific achievements, which are reasonably well known

Sir Eric Rideal (London) then gave an address on "Colloid Science a Century of Progress" Sir Eric reviewed the development of colloid chemistry since 1861, commencing with Graham's work on peptization, gels and sols He then discussed work on coagulation, flocculation and peptization of sols, drawing on the work of Von Weimarn, Hardy and Perrin for examples A review of optical investigations on colloidal solutions was then given, reference being made to the work of Faraday and Tyndall, and finally to the ultramicroscope of Zsigmondy and Siedentopf Gels and adsorption were dealt with rather more briefly, mention being made of the work of Freundlich and the swelling experiments of van Bemmelen

The final speaker in the morning session was Dr A S C Lawrence (Sheffield), who gave a talk describing the work of his group at Sheffield on soap–water–amphipile systems Graham did not carry out any investigations on soap solutions, but they come within his classification of colloids Dr Lawrence commenced with a general description of the colloidal and other phenomena encountered, and of the phase diagrams of the systems He continued with a more detailed account of the liquid crystalline forms and myelinic figures which are obtained on adding soap solutions to crystals of a polar additive, or solutions of additive to a soap crystal These were interpreted in terms of adsorption of soap and additive at the solid-liquid interface In conclusion, mention was made of the effect of organic and inorganic salts on the systems

For the afternoon session, the chairman was Sir Eric Rideal and the first speaker, Dr A P Prosser (London) Dr Prosser gave a talk on the forces which, in conjunction with electrostatic forces, stabilize all colloidal systems Beginning with a general account of van der Waals forces and London dispersion forces he then went on to deal with their origin and the differences which exist when bodies are very close together (< 250 Å apart, the unretarded case) or relatively far apart (> 2000 Å, the retarded case) He then gave a brief outline of the theory of the forces and the problem of evaluating them from the theory in the retarded and unretarded cases The experimental determinations of attractive forces by the groups led by Bradley, Derjaguin, Overbeek and Kitchener were then discussed, along with some recent experiments on flocculation in colloidal systems

The second paper in the afternoon, entitled "Polyelectrolytes", was by Prof J A V Butler and Dr D J R Laurence (London) and was read by Dr Laurence The subject-matter is directly connected with Graham's work on caramel and gelatin Dr Laurence mentioned the general properties of polyelectrolyte solutions such as high viscosity and gel formation He then went on to discuss more specialized properties such as titration curves, conductivity curves and transport properties which give rise to the picture of a polyelectrolyte molecule in solution as a charged random coil with small gegenions, some of which are 'free' and some 'trapped' inside the coil The last point is particularly well illustrated by measurements of transport number The spatial configuration of the coils was then discussed in terms of the information obtainable from sedimentation, viscosity and light-scattering measurements Finally, deoxyribonucleic acid was treated in rather more detail, followed by a mention of proteins, including ribonuclease

The final speaker, Prof J T G Overbeek (Utrecht), spoke on the drainage of soap films He began with a few general remarks on the structure of soap films, their thickness and colours. Then followed a description of the stretching of films, with the formation of new film, and the drainage of films Finally, the nature of the black film was discussed, with reference to the discontinuity in thickness at the edge of the black area, the forces giving rise to the black film and the ultimate breaking stability of the film when electrostatic and van der Waals forces are opposed to one another Prof Overbeek then presented a colour ciné film of the drainage of soap films illustrative of all the points he had mentioned, and containing, in addition, several beautiful illustrations of moving colour effects obtainable in soap films

A J Hyde

THE LIBRARY ASSOCIATION

ANNUAL CONFERENCE

THE papers presented at the annual conference of the Library Association at Hastings during September 19–22 were of general rather than specific interest to the scientist Mr Leslie Wilson and Viscount Caldecote made some reference to the National Reference Library of Science and Invention and the National Lending Library for Science and Technology and to the proposals for the re-organization of the Library Association, particularly as they seek to establish the Association as the professional association of librarians, and their papers are of direct consequence to scientists and technologists Sir Charles Snow's lively presidential address, with its plea for a wide view of the functions of the public library in the Welfare State, should also commend itself to them Sir Charles believes that the public libraries must in future assume some of the functions of the great private lending libraries and that, in particular, they have a real responsibility to contemporary literature which some of them have yet to recognize Mr K J Lea, county librarian of Essex, on the other hand, while not discounting this amenity aspect, to which the smaller library authorities are virtually limited, urged that more attention should be given to the educational and specialized services, if necessary by the development of a two-tier system based on co-operation between boroughs and counties, the possibility of which is already being demonstrated by the county libraries of Britain

Mr Leslie Wilson's paper, on "Libraries and Information Services the Challenge of the Future", was equally concerned with co-operation, alike between such bodies as the Library Association and the Association of Special Libraries and Information Bureaux and between these and institutions concerned with the use of information He stressed first the desirability of library and information work being recognized generally as a single distinctive professional activity and then the relevance of such an activity to the fragmentation of knowledge Effective special library work in any one field depends, he said, on co-operation between librarian and information officer and the specialist working in that field, and he suggested we have still far to go before the idea was generally accepted that accumulated knowledge, with the librarian as its vehicle, is as essential to industrial prosperity as capital investment, production and sales Viscount Caldecote indeed went some way in this direction when, in his paper earlier that day, he suggested that the research worker can reasonably expect library staff to be responsible for two-thirds of his library searching Mr Wilson thought, moreover, that we must expect a much greater participation of the Government in library affairs, and for all these reasons it would be wise for librarians and their organizations to clarify their ideas as to the form of partnership in which they could function most effectively

Mr Wilson cited the plans for the new National Reference Library of Science and Invention as a glaring example of the confusion and frustration likely to result from failure to achieve such co-operation and consultation between user and librarian at the earliest stage, but he also viewed with concern the proliferation of professional bodies concerned with such a relatively small field as library and information work Formal federation is probably impractical at present, but he suggested that some form of consultative committee or a series of consultative committees, each dealing with a special interest such as education or research, might help to achieve the closely knit community that is needed The Aslib Groups, he suggested, seem to be a reasonably successful means of dealing with the problem, but of the seventeen organizations listed in the handbook of special librarianship and information work as active in this field in the United Kingdom, at least the Library Association, Aslib, the Circle of State Librarians, the Standing Conference of National and University Libraries, the United Kingdom branch of the International Association of Music Libraries, the Association of British Theological and Philosophical Libraries and the Institute of Information Scientists should come closer together

Viscount Caldecote's paper expressed an industrialist's view and criticism of library and information services He thought that the main industrial library problem centre around the small firm He suggested first that the larger firms might make their own extensive library facilities available to these smaller firms, and that by doing so the trained library staff would enable the smaller firm to tap also the resources of the national libraries Viscount Caldecote repeatedly stressed the importance of quality of trained library staff, and he also suggested that member firms could do more to strengthen the library resources and services of the Research Associations He was impressed by the value of the area co-operative schemes formed in Sheffield, Newcastle upon Tyne, Liverpool and elsewhere, and in this connexion he thought the liaison thus established with educational bodies is of vital importance for the pooling of resources and knowledge Finally, in discussing briefly the functions and staffing of industrial libraries, themselves, Viscount Caldecote suggested that the Association might form a committee to study the automation of routine library services

Other papers presented at the Conference, by Dr C Bibby and by Mr A E Sanderson, dealt with the functions of training-college libraries, Mr B Williams firmly challenged the exercise of censorship in reading by a local authority or other body In his Library Association Annual Lecture, "The Fourth *R*", Dr Lincoln Ralph reviewed the limitations of an education confined to reading, writing and arithmetic in coping with the modern world, he urged that it is necessary not simply to instruct but also to inspire Education should impart a sense of values, of the purpose of life, and lead to a re-birth

THE AUSTRALIAN ATOMIC ENERGY COMMISSION

THE eighth annual report of the Australian Atomic Energy Commission*, which covers the financial year ended June 30, 1960, records a year of substantial progress in the high-temperature gas-cooled reactor project, in the production and application of isotopes, and in the installation and commissioning of new equipment

The report consists of nine sections dealing respectively with an outline of the activities of the Commission, the search for uranium, uranium mining, raw materials, including thorium and beryllium, research activities, isotopes, nuclear power, international agreements and co-operation with the International Atomic Energy Agency, and general activities Details of research contracts, postgraduate research studentships and undergraduate scholarships, together with the financial accounts and the names of the staff of the Commission, are given in appendixes to the report

Although the world's annual uranium production potential at present exceeds the demand, steadily increasing requirements for nuclear power stations are expected to develop from the 1970's onwards, and the Commission, through the Bureau of Mineral Resources, has continued its surveys for new deposits of uranium Except for one area stated to show anomalous radioactivity, no discoveries of radioactive materials were reported to the Commission during the year, but a number of further monetary reward instalments were paid for earlier discoveries

For the first time, complete production figures are given in the report for operations at Rum Jungle since the start-up in 1954 A record tonnage of ore was treated during 1959–60, and all the uranium oxide produced was delivered to the Combined Development Agency under the terms of the Rum Jungle Agreement, which expires on January 6, 1963. No mining was carried out during the year, and the treatment plant continued to operate on stockpiled ore

Full-power routine operation of the reactor *Hifar* began in February 1960 after a prolonged period of testing and calibration The reactor has given little trouble, and major irradiation work has been performed for the Commission and under contracts with the United Kingdom Atomic Energy Authority and the General Electric Company. The materials irradiated included prototype fuels, beryllium and beryllium oxide samples, and cobalt for the production of cobalt-60

---

* Australian Atomic Energy Commission Eighth Annual Report for the year ended 30th June, 1960 Pp 63 (Coogee, N S W Australian Atomic Energy Commission, 1960)

New buildings in the Research Establishment were officially opened on May 27, by the Minister for National Development, the Hon. W. H Spooner They consisted of the canteen, adjoining the building provided by the Commonwealth Government as the headquarters of the Australian Institute of Nuclear Science and Engineering, and a building devoted to isotopes and technical physics A 10-kW graphite moderated reactor, named *Moata*, ordered from the United States of America, is to be installed in the new reactor physics building to be finished this year *Moata*, which will have a maximum thermal neutron flux of 10^{11} neutrons cm $^{-2}$ sec $^{-1}$, is designed for flexibility of core and reflector arrangement, and will be used to measure thermal and resonance neutron cross-sections, to study slowing-down properties of moderators such as beryllium, and to investigate long-term changes in fuels and moderators Studies of the feasibility of a reactor system require intensive investigation into nuclear materials, and the various aspects of the research into the fabrication of graphite, beryllium, beryllium oxide, and sample fuel elements, the effects of irradiation on selected materials, and the compatibility of each material with the others, are described in some detail in the annual report For the study of beryllium and for work on solid-state physics in co-operation with the Commonwealth Scientific and Industrial Research Organization and Australian universities, two neutron collimators are in operation on *Hifar* for the production of neutron beams, a long wave-length neutron spectrometer has been installed, and two other spectrometers are being constructed

During the period under review, Australian industry showed increasing interest in the adoption of radioisotope techniques for the solution of its problems, but the field for potential industrial applications is still largely unexplored A second detailed survey of the extent of the applications of radioisotopes in Australian industry is being prepared, and information already available shows that a substantial increase since the first Commission survey in June, 1958, has occurred Two changes were made in the Advisory Service a direct consulting service to industry was initiated on a limited scale, and early in 1960 the Isotopes Section commenced making direct approaches to various firms Seventy technical discussions were held with inquirers at the Research Establishment and members of the Advisory Service made ninety visits to factories and laboratories In consultation with the Isotopes Section, the Commission's Engineering Services Design Group undertook the design of a cobalt-60 γ-irradiation unit for the study of plant mutations, and the long-term research programme includes the technical uses of radiation for insect pest control, sterilization of medical supplies and equipment, and food preservation by radiation At the end of May 1960 the Commission sponsored a conference on the "Technological Use of Radiation" The three-day conference was attended by 165 delegates, and sixteen papers were presented and discussed (the proceedings are now available in book form from the Melbourne University Press, Parkville, Melbourne, N 2, or from the Commission)

The number of staff employed at the Establishment increased by 189 to 673 during the year A few members of the Commission's scientific staff were stationed in the United Kingdom, United States of America and Canada, and an atomic energy attaché was appointed to the staff of the Australian Ambassador in Washington for closer working contact The Commission provided £60,000 for the building housing the Australian Institute of Nuclear Science and Engineering which was opened in May, and gives £50,000 annually for Institute research and training Although no undergraduate scholarships have been awarded since 1957, ten students are still undergoing training in geology, geophysics, metallurgy and chemical engineering The students graduate this year Forty-three research contracts have been awarded to eight universities and two hospitals

MENTAL HEALTH

THE tenth report of the World Health Organization Expert Committee on Mental Health is devoted to a review of present mental health facilities and resources and to the establishment of priorities for a mental health programme on a world-wide scale* Essentially it is based on a summary of work carried out in the field of mental health by the World Health Organization during 1949–59, and on the responses to an inquiry circulated to specialists in many countries in an attempt to ascertain what is being done and what needs to be done in that field

The report first examines trends in mental-health work during the past decade, covering such subjects as mental health aspects of public health, psychiatry of childhood, treatment methods and facilities, organization of psychiatric services, education and training, and research. Under each heading attention is directed to the contribution made by investigations sponsored by the World Health Organization, particularly those reflected in the reports of previous Expert Committees and Study Groups

An examination of the aims of mental-health work and of the ways of achieving them is followed by a discussion of psychiatric and mental-health services, their organization, planning and priorities Emphasis is placed on the importance of training programmes, since "even the most efficient organization and the best physical facilities will not prevent a badly staffed service from soon becoming unsatisfactory" The training of each category of mental-health worker is dealt with in turn. In addition, an idea is given of the kind of education in mental health required for personnel from the other health professions, as well as for community leaders and the general public, so that all may help to promote the mental health of the community

The report touches briefly on team work and describes the attitudes required in a team leader and qualities desirable in team members Considerable space is given to research in the field of mental health and it is pointed out that, although investigations undertaken in various countries over recent years show encouraging results, the complexity of the problem makes progress slow The areas of research considered of foremost importance in mental-health work are enumerated and discussed in detail Among the many subjects recommended for investigation are studies on brain function, epidemiology, health and social studies of communities undergoing rapid change, the hospital *milieu*, ecology of mental illness, problems of ageing, the effect of nutrition on mental health, and genetics

* World Health Organization Technical Report Series No 223 *Programme Development in the Mental Health Field* Tenth Report of the Expert Committee on Mental Health Pp 56 (Geneva World Health Organization, London H M S O , 1961) 2 Swiss francs, 3*s* 6*d* , 0 60 dollars

The report concludes with a consideration of the vital part that the World Health Organization can play in future planning for mental health, by fostering international co-operation and exchange of information, and by facilitating and stimulating research

APPLICATION OF PALÆOMAGNETISM TO THRUST MECHANICS

By D K. NORRIS and R F BLACK

Geological Survey of Canada, Ottawa

THE surface trace of the Laramide Lewis thrust fault in the south-eastern Cordillera of Canada exhibits a change in direction of approximately 35° from a north-west trend east of the Clark and Lewis Ranges to a north trend east of the Flathead Range (Fig 1) The nature and genesis of this change of direction has been the subject of much controversy in recent years, and explanations have included differential erosion of the thrust plate and differential rotation of the plate The purpose of this article is to show that palæomagnetic directions in conjunction with surface geological data suggest that the Lewis thrust plate moved as a coherent tectonic unit and that the gross geometry of the plate may have been established at the time thrusting was initiated

For convenience in reference, the Lewis thrust plate will be divided geographically into two parts, termed respectively the Flathead Range segment and the Clark and Lewis Ranges segment

These two parts are structurally and stratigraphically continuous with one another at their common boundary in the vicinity of North Kootenay Pass Precambrian rocks of the Purcell system have been mapped without interruption between them, and no major transverse faults are there to suggest that the two segments of the Lewis thrust plate operated as independent tectonic units[1] The continuity as well as the simplicity of the structure between the two segments would suggest rather that the plate moved as a single structural unit

The change in trend of the surface trace of the Lewis thrust therefore must be due either to differential erosion of the plate, such that the Flathead Range segment has been eroded to some considerable degree farther west than the Clark and Lewis Ranges segment, or to the possibility that the latter segment was always structurally farther east than the former The fact, however, that the fold and thrust fault elements in the Clark Range do not end abruptly at the margin of the plate where the surface trace of the Lewis thrust swings west but rather swing sub-parallel to it suggests that the re-entrant at North Kootenay Pass is not due to differential erosion of the Lewis thrust plate The possibility of differential rotation, therefore, is especially impor-

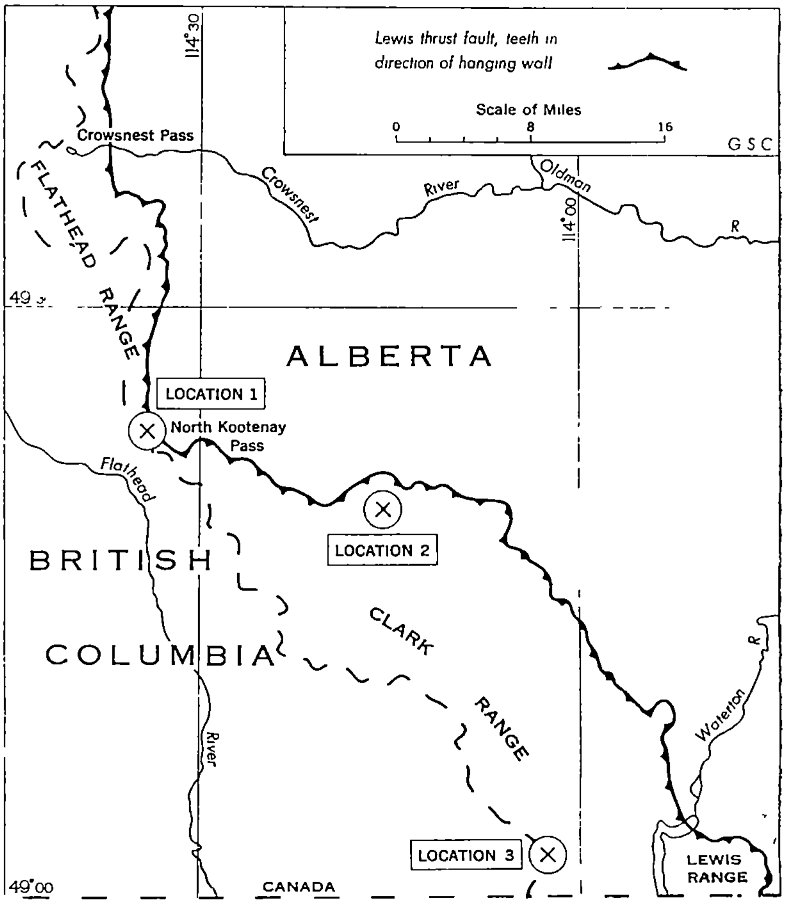

Fig 1 Location map

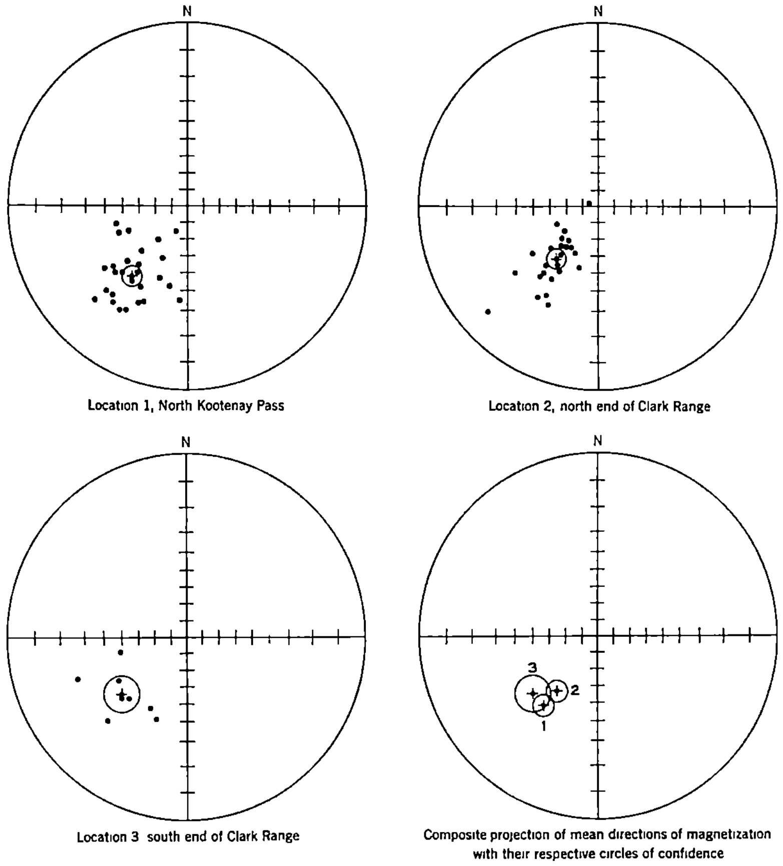
tant in the interpretation of the mechanics of emplacement of the plate.

If differential rotation has occurred it should be possible to determine the approximate amount of relative motion by a comparison of the directions of the remanent magnetic vectors obtained from Purcell samples collected in the two segments A necessary condition, however, is that the time of magnetization of the rocks making up the plate be pre-Laramide (older than Early Tertiary) in order that the results obtained can be applied to this problem

Fifty-nine samples of unweathered, highly quartzose, fine-grained, red sandstone were collected from the Precambrian Purcell system at intervals normal to the strike at three locations in the Lewis thrust plate (Fig 1) They were from member *A* of the Kintla formation in the Flathead Range where the strata strike north, and, from members *A* and *C* of the same formation, at two localities in the Clark Range where the strata strike north-west

The remanent magnetization in each of two cubes from each sample of Kintla formation was determined with a sensitive astatic magnetometer in the laboratories of the Dominion Observatory of Canada From the measurements of two cubes the mean attitude of the remanent magnetic moment was computed for each sample



Location 1, North Kootenay Pass

Location 2, north end of Clark Range

Location 3 south end of Clark Range

Composite projection of mean directions of magnetization with their respective circles of confidence

Fig 2 Stereographic projections of the directions of magnetization for the three locations and composite projection of their respective mean directions and circles of confidence ●, vectors pointing downwards, +, mean direction of magnetization

All cubes were subjected to decreasing-amplitude-alternating-field demagnetization and the maximum amplitude of the field was progressively increased after each set of measurements until no significant change (less than 5°) occurred in the magnetization direction in the cubes This approximately stable state of magnetization was reached at 156 œrsteds

Results from this demagnetization treatment indicate that the Kintla formation, where sampled, is magnetically stable, as the directions of magnetization for the majority of cubes were not significantly altered After demagnetization the directions in the remainder became consistent with those on which demagnetization had little or no effect

The mean palæomagnetic results for the three localities sampled are indicated in Table 1 and plotted in Fig 2 Solid circles plotted on the Wulff stereographic projections in Fig 2 represent the directions of the magnetic vectors with their positive pole pointing downwards The mean direction for each group of samples is represented by a solid circle centred by a cross The statistical parameters computed for the three groups of measurements are N, θ, and K as defined by Fisher[2], where N is the number of samples, θ is the radius of the circle of confidence calculated at the 95 per cent level of confidence (represented in Fig 2 as open circles on the lower hemisphere of the stereographic projection), and K is a measure of the dispersion All measurements are with respect to bedding, which was assumed to be horizontal at the time of deposition

The fact that the calculated pole positions included in Table 1 agree well with those pole positions determined from Purcell and other Late Precambrian North American rocks[3,4] would suggest that the remanent magnetization has been preserved since Precambrian times The results may therefore be applied with reasonable assurance to test for the possibility of differential rotation in the Lewis thrust plate in the early tertiary

The directions of the magnetic vectors of samples from member *A* were in all cases found to point upwards and have been adjusted (sign of the inclination changed from negative to positive and 180° added

Table 1 MEAN PALÆOMAGNETIC RESULTS FOR INDIVIDUAL COLLECTING SITES

		Location 1	Location 2	Location 3
Collecting site		North Kootenay Pass	North end of Clark Range	South end of Clark Range
Formation and member		Kintla *A*	Kintla *A* and *C*	Kintla *A*
Polarity *		–	– and +	–
Number of samples		27	24	8
Mean declination		218 5°	218 0°	230 0°
Mean inclination		+39 5°	+49 0°	+38 0°
θ		5 5°	6 5°	9 5°
K		23	24	40
Ancient pole position	Lat	10 5° S	3 0° S	6 5° S
	Long	150 5° W	146 5° W	159 0° W

* For comparative purposes all vectors have been adjusted to point downward

to the declination) to point downward for comparison of results from members A and C

It is evident from the composite projection in Fig. 2 that the circle of confidence for any one group of observations is intersected by those of the other two groups This would suggest that within the limits of error of collection and measurement, which is between 5° and 10°, little if any relative rotation of the Kintla formation has occurred between any of the three collection sites The differences in the mean declination angles are negligible between Flathead Range and the north end of the Clark Range and has a maximum of 12° between the latter and the south end of the Clark Range It should be recalled that if the change in trend of the surface trace of the Lewis thrust were due entirely to differential rotation a disparity in the declination of the order of 35° should be indicated

In summary, the continuity of surface structural and stratigraphic units throughout the length of the Lewis thrust plate in the area under investigation would suggest that the plate moved as a single, coherent, tectonic unit with no major transcurrent or transverse normal faulting Palæomagnetic data, moreover, support this contention as there was, within the limits of error, no measurable differential rotation of the plate between the Flathead and the Clark and Lewis Ranges It appears, therefore, that the Clark and Lewis Ranges were always structurally farther east than the Flathead Range The present configuration of the eastern limit of the Lewis thrust plate is apparently genetically related to the geometry of the thrust surface established during the initial stages of movement rather than to differential erosion along the eastern margin of the plate

LOSS OF FLUORESCENT PARTICLES IN ATMOSPHERIC DIFFUSION EXPERIMENTS BY COMPARISON WITH RADIOXENON TRACER

By A E. J EGGLETON
Health Physics Division, Atomic Energy Research Establishment, Harwell
AND
N THOMPSON
Meteorological Office and War Office, Chemical Defence Experimental Establishment, Porton Down, Nr Salisbury

ZINC cadmium sulphide, disseminated in a finely ground particulate form, mainly in the size-range 1–5μ, has been widely used as a tracer in work on diffusion and atmospheric pollution This fluorescent tracer technique was described independently by Perkins *et al* [1] and Braham *et al* [2] in 1952 The various problems in which it has been used can be conveniently divided into two groups The first includes investigations of the spread of airborne substances released into the atmosphere Here, only relative measurements of the concentrations of the particles are important in a particular trial, and provided any comparison of these is made after equivalent times of travel, then any time-decay of the tracer in a physical or chemical sense is unlikely to introduce error. The second is of particular importance in air-pollution investigations and includes all problems where the tracer is used to estimate the absolute concentration at any position resulting from a release of known size Here, the decay characteristics of the tracer must be well defined

Earlier workers[1,3] considered that zinc cadmium sulphide was stable in the presence of normally occurring concentrations of atmospheric pollutants for at least the first few hours after release However, some work by one of the present authors (N T), to be reported elsewhere, in which vertical profiles of the particles were investigated some tens of kilometres down wind of releases on a long cross-wind line, showed an apparent decrease in the number of airborne particles with increasing distances of travel A more reliable estimate of the loss was required, and it was decided to compare the fluorescent tracer directly with an inert gaseous tracer Radioactive xenon-133 (half-life 5 27 days) was selected because of ease of sampling and detection

The xenon and zinc cadmium sulphide tracers were released simultaneously at a uniform rate and sampled simultaneously at two distances down-wind The total amount (number of particles or activity) of either tracer collected, divided by the sampling rate, is a measure of the dosage (time-integral of volumetric concentration) of that tracer at the point in question If D_1, D_2 are the dosages of xenon at the near and far sampling distances respectively (units, μμc min /m ^{3}) and d_1, d_2 the corresponding dosages of particles (units, particle min /m ^{3}) then L, the percentage loss of particles, is given by

$$L = \left(1 - \frac{D_1}{D_2}\bigg/\frac{d_1}{d_2}\right) \times 100$$

This result is independent of the position of either sampling station with respect to the plume axis

On each of three days, approximately 10 kgm of zinc cadmium sulphide (Derby Luminescents 1318/10) and 3 curies of xenon-133 were emitted from a 20-metre incinerator stack at the Atomic Energy Research Establishment, Harwell, over a period of about 2 hours beginning near noon Calculation showed that the health hazard to a person situated at the point of maximum ground-level concentration was negligible During the three trials reported here, the wind directions varied between south-west and west-north-west with mean speeds of between 4 and 7 m /sec Vigorous convection extended to heights of up to 1,700 m and there was about one-half cloud cover present

Sampling of both tracers took place at two stations placed one about 16 km and the other about 60 km

Table 1

	June 23, 1961		July 7, 1961		July 25, 1961

(*a*), Assessment under 80 × microscope, (*b*), higher intensity ultra-violet illumination and 100 × microscope used in assessment.

from the source. A sampler was also operated about 1 km. up-wind of the source to measure the background activity of atmospheric xenon. Satisfactory positioning of the sampling stations in the plume of material was obtained through frequent pilot balloon measurements of the wind at Harwell, and by direct observation of the bearing of the plume axis a few kilometres from the source, using a mobile fluorescent particle sampler in conjunction with inspection equipment set up nearby.

The fluorescent particles were collected by drum impactors, through which air was drawn at a rate of about 20 litre/min. The drums were rotated through a small angle at 5-min. intervals to prevent a large accumulation of dust on the traces, which might have obscured a significant number of the impacted particles. In the subsequent assessment, the drums were illuminated with ultra-violet light and the particles counted through an 80 × microscope. The samples from the third trial were also assessed under ultra-violet light of higher intensity, with counting under a 100 × microscope.

The xenon-133 was collected by passing air from a petrol-driven compressor at a flow-rate of 100 litre/min. through a charcoal U-trap immersed in a dry-ice alcohol mixture at $-78°$ C. The trap contained 400 gm. of activated charcoal and was preceded by a soda-lime column to remove carbon dioxide, a magnesium perchlorate drying column and a pre-cooling coil. The trap was followed by a warming coil and a rotameter.

After sampling was completed, the charcoal trap was returned to the laboratory where a measured volume, approximately 10 ml., of inactive carrier xenon was added. The trap was then heated slowly to about 200° C. and the xenon, together with some oxygen, nitrogen and other gases, was flushed with purified hydrogen into a smaller charcoal chromatographic column immersed in liquid nitrogen. The xenon was separated from other gases by a gas chromatographic technique using hydrogen as the eluting gas. A measured volume of the xenon, together with diethyl ether vapour as a quench, was transferred to a 50-ml. Geiger counter. This was operated in a low-background assembly with an anti-coincidence ring. Counter backgrounds were about 1.5 c.p.m. and the minimum sample count-rate approximately 10 c.p.m. The chemical purity of the separated xenon was established by mass-spectrometric analyses. Radon was the principal radioactive impurity expected and its absence was demonstrated by operating the counter in the proportional region to enable any radon α-pulses to be distinguished from the xenon-133 β-pulses, and also by following the decay of each sample for at least one half-life. Count-rates were corrected for radioactive decay to a standard time and an allowance was made for the xenon lost in processing and transfer to the counter. The correction due to xenon background activity did not exceed 20 per cent of the sample activity. The collection efficiency of the field sampling equipment, determined in separate experiments, was better than 85 per cent for periods up to 4 hours, and a small correction was made, appropriate to the duration of sampling after arrival of the xenon-133 at the sampling station. A full description of the xenon sampling technique will be published elsewhere.

The results are summarized in Table 1.

The mean loss of particles in travelling between the two sampling stations is seen to be approximately 50 per cent. A several-fold increase in the intensity of ultra-violet light used in the assessment of the fluorescent particle samples resulted in an increase of about 25 per cent in the number of particles counted in the last trial. However, the dosage ratios from the two assessments were almost identical and the corresponding values for the loss of particles differed by less than 4 per cent. The explanation for the loss is unknown at present, but it is relevant that separate studies of the size spectrum of the particles after different distances of travel showed an apparent decrease in the proportion of small particles with increasing distances of travel. Measurements[4] on particles collected in these last experiments showed that the fluorescent brightness of particles less than 2.5μ diameter decreased with increasing time of travel. To account for the loss by deposition, a velocity of deposition of 1.5 cm./sec. would be required, which is about 60 times larger than the value determined in wind tunnel experiments (Chamberlain, A. C., personal communication). In any event, this process would lead to a preferential loss of the larger particles.

Our thanks are due to D. V. Booker (Atomic Energy Research Establishment) for advice and assistance in counting the xenon samples, also to G. F. Collins and R. A. Titt (Chemical Defence Experimental Establishment) for assistance with certain aspects of the fluorescent tracer technique.

STRUCTURE OF THE 5,6-DIMETHYLBENZIMIDAZOLYLCOBAMIDE COENZYME

By Dr. P. GALEN LENHERT* and DOROTHY CROWFOOT HODGKIN, F.R.S.
Chemical Crystallography Laboratory, Oxford

RECENTLY, H. A. Barker *et al.* reported the isolation of a crystalline 5,6-dimethylbenzimidazolylcobamide (DBC) coenzyme[1]. This is one of a series of coenzymes which were first recognized as catalysts in the conversion of glutamate to β-methylaspartate in certain bacteria. The coenzyme was shown to be active in systems requiring vitamin B_{12}, but it differed from cyanocobalamin in having an adenine nucleoside in place of the cyanide group. We have now carried out an X-ray analysis of the coenzyme structure, having for our use crystalline preparations kindly given to us by Dr. H. A. Barker, Dr. Karl Folkers and Prof. A. W. Johnson.

Part of Dr. Barker's preparation was recrystallized by slowly diffusing acetone into an aqueous coenzyme solution. Two freshly grown crystals prepared in thin-walled glass capillary tubes in dim light and kept in contact with their mother liquor were used to obtain the X-ray diffraction data for the structure analysis. Copper *K*α radiation was used throughout. The intensity measurements were made visually from multi-film equi-inclination Weissenberg photographs taken about the *b* and *c* axes. The Lorentz-polarization correction and a spot shape correction were applied. The scale factor for each layer was calculated from reflexions common to other layers and the absolute scale was obtained by Wilson's method. 3,145 independent reflexions extending out to a spacing limit of 0·9 Å. were observed. These included about 85 per cent of the reflexions with a spacing greater than 1·2 Å.

The unit cell dimensions characteristic of the wet crystal lattice, as measured from precession photographs, are $a = 27 \cdot 9_3$, $b = 21 \cdot 7_3$ and $c = 15 \cdot 3_4$ Å. The space group is $P2_12_12_1$ and the measured density of the fully solvated crystals, $1 \cdot 35_5 \pm 0 \cdot 01$ gm./cm.^{3}. The molecular weight, coenzyme plus solvent, calculated from this information is 1,899. This is larger, as would be expected, than the weight measured by Mattern on air-dried crystals[2], the difference corresponds to the weight of about 8 molecules of water of crystallization.

The structure analysis began with the calculation of a sharpened three-dimensional Patterson synthesis which clearly showed the Co—Co vectors. The first electron-density synthesis was computed using phases calculated from the cobalt positions and the observed *F* values weighted according to a method suggested by Sim[3]. The resulting electron-density map contained peaks representing most of the atoms in the structure, and in addition, spurious peaks, many of which were larger than those corresponding to atoms. The position of the cobalt atom ($z = 0 \cdot 02$) produced a pseudo-mirror plane which distorted the electron-density pattern representing the corrin nucleus and increased the number of spurious peaks. In spite of this, reasonably accurate positions were worked out for nearly all the atoms in the corrin nucleus, the 5,6-dimethylbenzimidazole, the ribose and the phosphate group.

A second electron-density synthesis, again using Sim's weighting scheme, was computed with phases calculated from the 54 atoms with known positions. This synthesis, containing less false symmetry and fewer spurious peaks, enabled us to place nearly all the remaining atoms of the coenzyme molecule. The electron-density in the region above the corrin nucleus, on the side occupied by cyanide in cyanocobalamin, is of particular interest (Fig. 1). The adenine moiety can be clearly seen among the spurious peaks. It is evident as a planar set of peaks with the 5- and 6-membered rings and the amino-group correctly related. Further, the five nitrogen atoms, with one exception, correspond to the peaks of greater electron-density. The sugar part of the nucleoside is not so easily seen, but on careful study it is no less convincing. This arrangement of peaks represents a *d* ribose unit linked directly to the cobalt atom at C 5′. No peak can be found which would correspond to the hydroxyl oxygen of C 5′. Most of the spurious peaks are in chemically inadmissible positions and have disappeared from subsequent electron density syntheses.

Any residual doubt about the correctness of the above interpretation was completely dispelled by the results of the next structure factor calculation and the appearance of the corresponding difference synthesis. All the atoms in the coenzyme molecule (except six in the vitamin B_{12} part) and three water molecules were included in the third structure factor calculation. The agreement factor, *R*, was thereby reduced from 0·44 to 0·28.

Agreement between the observed and calculated structure factors has been further improved by adding the remaining six atoms of the vitamin B_{12} part, by including additional solvent molecules and by making adjustments in the positional and thermal parameters

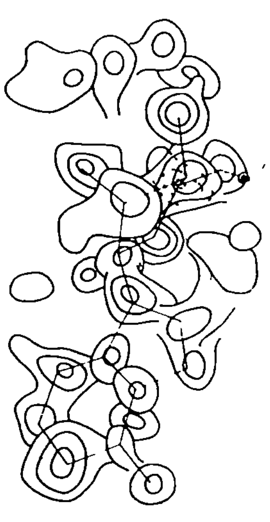

Fig. 1. Peaks in the second electron density synthesis in the region of the adenine and sugar groups. The contours are at levels corresponding approximately to 1·0, 1·5 and 2·0 $e/\text{Å}^3$. The distribution is shown viewed along *a* and the contours are drawn only near the level of the peak maxima

---

* Present address: Physics Department, Wittenberg University, Springfield, Ohio.

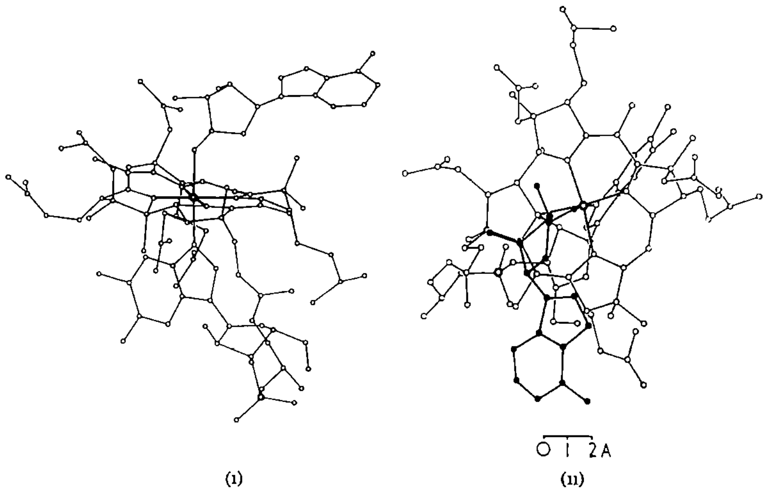

Fig. 2. The atomic positions in one molecule of the 5,6-dimethylbenzimidazolylcobamide coenzyme as found in the wet crystals and viewed along (i) the *b* axis, (ii) the *a* axis. In (ii) the atoms of the nucleoside unit are marked by filled circles

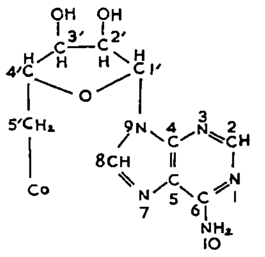
of the other atoms. All the atoms of the coenzyme molecule (excluding hydrogen) and contributions from 11 water molecules have been included in the latest structure factor calculation. The agreement factor is 0·173.

The structural formula of the nucleoside as it occurs in the intact coenzyme should almost certainly be written as in I, which represents it as an adenosine derivative.



(I)

The *d* ribose unit and the adenine are linked at C 1′ (β) and N 9 in accordance with the observations of Ladd *et al.*[4] The unsaturated sugar, $CH_2 = CH \cdot CHOH \cdot CHOH \cdot CHO$, which these authors obtained by the action of cyanide or mild acid hydrolysis, must be formed on degradation of the coenzyme following the rupture of the Co—C 5′ bond. The observed tetrahedral character of the atomic centres C 2′, C 3′ and C 4′ makes it unlikely that a double bond involving any of these atoms is initially present in the molecule, and very recently, adenosine derivatives in which the pentose ring is intact and the 5′ CH_2OH is replaced by COOH and CHO have been isolated from among the photolysis products of the coenzyme by Johnson and Shaw and by Barker *et al.*[5]

Fig. 2 shows the arrangement of the atoms in the coenzyme molecule as found in this crystal structure. All the atoms of the vitamin B_{12} molecule appear to be present except the cyanide group which has been replaced in the coenzyme by the adenosyl residue. The cobalamin nucleus and the nucleoside are connected by the C 5′—Co bond of 2·05 ± 0·05 Å, the Co—C 5′—C 4′ angle is rather large, 130°, which suggests that this bond may have partial ionic character. No other direct covalent or hydrogen bonds connect the corrin nucleus and the nucleoside. The closest non-bonded contact is 3·1 Å.

While several of the amide side-chains have adopted conformations different from those found in B_{12}, there is no evidence of any change in the corrin nucleus itself. Within the accuracy of the present partly refined co-ordinates, the corrin nucleus appears to be identical in the vitamin and coenzyme molecules. In the circumstances we could most easily formulate the cobalt atom as trivalent in the coenzyme molecule and write the structure in a similar way to that of vitamin B_{12}. The coenzyme molecule would then have a molecular formula of $C_{72}H_{100}O_{17}N_{18}PCo$ and a molecular weight of 1,580. The uncertainties here are in the number of hydrogen atoms, the valency of cobalt and the exact character of the bonding in the corrin nucleus, they may possibly be resolved by further refinement of the crystal structure, particularly if we can observe the hydrogen atom positions. Other evidence, notably on the magnetic character of the crystals, is very conflicting at present[6,7] and it seems likely that easy transformations occur within the molecule which involve the valency of cobalt and the corrin nucleus. These, combined with the unusual character of the carbon–cobalt bond, are presumably responsible for the catalytic activity of the coenzyme.

The crystal structure of the DBC coenzyme is, in detail, quite different from that found in the vitamin B_{12} crystal structures. Although the orientation of the corrin nucleus with respect to the crystal axes is similar, the relationship between the four molecules which make up the translational unit of the crystal has altered. In the new arrangement, very interesting intermolecular contacts arise which suggest methods of approach by different reagents in the neighbourhood of the Co—C 5′ bond. For example, the adenosyl 3′ OH is hydrogen bonded to the phosphate group of one neighbouring molecule while the NH_2 group of the adenine unit is in contact with the phosphate group of another. The geometrical relations strongly suggest easy pathways both for the formation of the coenzyme from adenosine triphosphate and for its possible intervention in nucleic acid synthesis.

We wish to thank Dr. J. S. Rollett for the use of his structure factor programme and for many helpful discussions. The Fourier series programme written by Dr. O. S. Mills and other programmes written by various members of this Laboratory have greatly facilitated the work. All the calculations were done on the Ferranti *Mercury* computer with the co-operation of the staff of the Computing Laboratory, Oxford. This investigation was carried out during the tenure by one of us (P. G. L.) of a postdoctoral fellowship from the Division of General Medical Sciences, United States Public Health Service.

VARIANTS IN THE STRUCTURAL POLYSACCHARIDES OF ALGAL CELL WALLS

By Dr. EVA FREI and Prof. R. D. PRESTON, F.R.S.

Botany Department, University of Leeds

ALTHOUGH the wall polysaccharides of the algae have been extensively investigated there are nevertheless many puzzling features which remain to be resolved. We have for this reason been making detailed examination of the walls of a wide variety of these plants, and it is the purpose of this article to present these newer results in the general context of the older, pending more extensive publication elsewhere.

It has long been recognized that the walls of plant cells consist of two phases, one a dispersed crystalline phase and the other a matrix which is commonly non-crystalline, both phases containing largely polysaccharides and/or polysaccharide derivatives. Since 1948 the dispersed phase has been identified in the electron microscope as consisting of long thin threads—the microfibrils—and it has become the custom, except in most fungi, to associate these with cellulose. In higher plants, the microfibrillar component usually occupies a large proportion of the wall volume so that the wall normally gives a characteristic X-ray diagram of cellulose I (native cellulose). In the algae, however, the relative volume of the crystalline wall material is often so small that the scatter from the amorphous incrusting substances may mask the X-ray diagram completely, and microfibrils may no longer be visible when chemically untreated material is examined in the electron microscope.

In 1952, Nicolai and Preston[1], using in the main the technique of X-ray diffraction analysis of untreated algae, divided the Chlorophyceae into three groups so far as wall structure is concerned. Group 1 consisted of the Valoniaceae and the Cladophoraceae (with the exception of the *Spongomorpha* group of the Cladophorae), algae containing highly crystalline cellulose I in abundance in the form of relatively straight and comparatively thick microfibrils. The bulk of the plants were placed in Group 2, characterized by X-ray diagrams resembling those of cellulose II (mercerized cellulose) and the rest, giving unidentifiable X-ray diagrams, made up Group 3. It was afterwards reported from this laboratory that the marine Phaeophyceae[2] and, with one exception, the Rhodophyceae[3] resemble in this regard the green algae of Group 2. The classification was regarded throughout as provisional because the interpretation of the X-ray diagrams of untreated algae in Groups 2 and 3 was scarcely ever unambiguous. This was due both to uncertainties inherent in the possible masking of reflexions by scatter from amorphous substances and to the presence in some diagrams of reflexions referring clearly to two different crystalline substances.

The major difficulties in the way of an identification of the crystalline component of algal cell walls lie partly in the need for careful removal of incrusting substances and partly in the invariable presence in marine algae of a deposit of micro-crystalline material on the plant surfaces[4]. This deposit, which is often present in large amounts, especially in filamentous algae, we have identified as a mixture of clay minerals. As it cannot be removed, even by the most severe washing, the X-ray diagram of untreated algae is often that of the clay minerals alone. It is undoubtedly because the strongest three reflexions of the mixture of minerals present lie very close to the strongest reflexions of cellulose II, both in disposition and in spacing, that cellulose II has been suspected to be the skeletal substance of Group 2 algae. Chemical treatment can reduce this contamination to an amount usually so small as to allow the diagram of the crystalline wall polysaccharides to be recognized. In particular, the treatment used by Jermyn and Isherwood[5] and adapted by Cronshaw, Myers and Preston[2] for the isolation of α-cellulose progressively removes the clay minerals, with a consequent progressive change in the X-ray diagram of the wall as reported and found confusing by the latter authors[2].

With these points in mind we have examined representative plants from most groups of the marine algae, using in the main the techniques of X-ray diffraction analysis and paper partition chromatography of hydrolysates of wall fractions, supplemented by electron microscopy and, very occasionally, polarization microscopy. The plants are dealt with in turn according to the nature of the crystalline wall substance present.

The X-ray diagrams of all the members of the Rhodophyceae we have examined, chosen to be representative of the group, are consistent with the presence of cellulose I as the skeletal substance, except in the Bangiales, a member of which will be discussed separately. The cellulose content of the wall and the degree of crystallinity of the cellulose are both rather low. The X-ray diagram is therefore revealed only after extensive removal of incrusting substances. For this removal, solutions of potassium hydroxide stronger than 10 per cent should not be used since with the red algae these solutions convert the cellulose I to cellulose II. The microfibrils contain a range of sugar residues other than glucose residues[2]; but it has recently been shown for one species at least that the central core of the microfibrils consists of cellulose I (ref. 6) alone. In all the Phaeophyceae we have examined, the X-ray diagrams again demonstrate clearly the presence of cellulose I as already reported for *Fucus*[7]. The clarity of these diagrams and the sharpness of the arcs distinguish them clearly from those of the red algae. Moreover, mercerization of the cellulose in the brown algae in potassium hydroxide solutions does not proceed at concentrations below 14 per cent. In the holocellulose of most of the Fucales examined an intense reflexion appears on the X-ray diagram corresponding to a spacing of about 14·1 Å. This indicates the presence of another crystalline wall substance, though we are not certain whether this is originally present in untreated material or whether crystallization is induced by the treatment involved. Untreated material from stipes of *Alaria* (but not from the laminæ) undoubtedly contains a second crystalline component in addition to the cellulose.

The Chlorophyceae are, however, by no means so uniform as regards the nature of the skeletal substance, though cellulose I is again to be found in many families. There is no need here to document the presence of highly organized and well-crystalline cellulose I in the algae of Group 1, though some remarkable features of some plants in this group have only recently been pointed out[8]. Other members of the Chlorophyceae are also now known to contain this substance, including *Nitella*[9], *Ulva*[9] and *Ulothrix*, and perhaps *Spirogyra*[10], though there are peculiar features in this last species. The condition of the cellulose resembles that in either the Phaeophyceae or the Rhodophyceae, and all these algae should clearly be separated from those of Group 1.

The incrusting substances of the algal walls containing cellulose I as the crystalline component are constructed from uronic acids and a wide variety of sugars[3]. Among the sugars, galactose, arabinose and xylose predominate.

Beyond these, one plant in particular, namely, *Halicystis* (Siphonales) was long ago reported to contain cellulose II in [place of cellulose I (ref. 11). Hydrolysates of the whole wall contain about equal quantities of glucose and xylose, and extraction of the wall with caustic soda solutions of increasing strength leaves unchanged both the X-ray diagram and the proportion of sugars in the hydrolysates of the residue[12]. The X-ray diagram contains arcs attributable to cellulose II together with a reflexion at about 13 Å. (12 Å. in our photographs) spacing which Roelofsen *et al.*[12], correctly in our view, refer to the large amount of xylan present. We have found that treatment of *Halicystis* holocellulose with caustic potash solutions of progressively increasing concentration causes a progressive decrease in the intensity of the arcs of long spacing, and that 4 *N* potassium hydroxide causes their final disappearance leaving the diagram of cellulose II. Hydrolysates of the very small residue (so-called α-cellulose) nevertheless still contain, besides glucose, about 40 per cent of xylose. Separation of the glucan and the xylan can, however, be achieved by treatment of the wall with cuprammonium. Most of the glucan dissolves and the precipitate gives an X-ray diagram of cellulose II. The residue insoluble in cuprammonium contains predominantly xylose residues and gives an X-ray diagram identical with that of the xylan to be discussed further on. We may compare the condition in *Halicystis* with that reported by Kreger[13] for *Hydrodictyon* (Chlorococcales), a fresh-water alga. The walls of these plants contain glucan and mannan only, but neither of these yields an X-ray diagram until the wall has been treated chemically with, for example, dilute mineral acid. A composite diagram of both cellulose II and mannan is then obtained, symptomatic of a crystallization of glucan and mannan chains which, in the fresh wall, were at the most in a paracrystalline state.

Halicystis and *Hydrodictyon* are very special cases since only two sugars are used in the construction of the wall, and the boundary between crystalline and para- or non-crystalline phases must be vague. In these algae, in addition to glucose, mannose and xylose respectively must play an important part in both phases. Among the Siphonales there are other algae in which xylose or mannose form the only crystalline wall component and we now discuss these in turn.

Untreated walls of *Bryopsis*, *Caulerpa*, *Penicillus*, *Udotea* and *Halimeda* (all Siphonales) yield a remarkably distinct X-ray diagram which is quite different from that of cellulose and the spacings of which are listed in Table 1. Treatment of the material with boiling water, followed by chlorination and extraction with dilute alkali solution, leaves the diagram unchanged. In stronger alkali (10–18 per cent potassium hydroxide according to species) the wall dissolves. Suspensions of cell wall material of any of these species dried down to a thin film on glass show uniplanar orientation, that is, certain planes in the crystal lattice tend to lie parallel to the film (and therefore the cell wall) surface. The inner wall layers of the large filaments of *Penicillus dumetosus* give an X-ray diagram, illustrated in Fig. 1, which demonstrates that the crystallites in the wall lie parallel to filament length. *Penicillus* walls so treated as to remove incrusting substances (containing mainly glucose residues) yield, on hydrolysis, xylose together with a little glucose. The X-ray diagram (Fig. 1) is quite certainly not that of the β-1,4-linked xylan which can be isolated from the incrusting substances of cellulosic walls (cf. col. 1 and col. 2 in Table 1). The diagram does, however, resemble in character though not in detail those obtained from yeast glucan[14] and certain preparations of laminarin (Nicolai, E., unpublished results), both recognized β-1,3-linked glucans. Mackie and Percival[15] and Iriki *et al.*[16] have shown that the xylan of *Caulerpa*

is β-1,3-linked, and the latter authors have demonstrated the same linkage also in the xylans of *Bryopsis*, *Udotea*, *Halimeda* and some others. The X-ray diagram is therefore certainly that of β-1,3-linked xylan, and this is the crystalline component of the walls of these plants.

In the electron microscope, the cell walls of all these 'xylan weeds' are seen to be microfibrillar, illustrated here by an electron micrograph of an inner wall lamella of *Penicillus* filaments (Fig. 2). Of the two kinds of fibrillar bodies visible in Fig. 2, one, running approximately parallel to filament length (and about 100 Å. wide), resembles closely the microfibrils common in cellulosic walls. The other, less-abundant kind, lying approximately at right angles to the first, are not true microfibrils. The fibre diagram of inner layers (Fig. 1) clearly has its origin in the longitudinally oriented microfibrils. The birefringence of the wall, both in face view and in optical section, is nevertheless negative. This of necessity implies that the longitudinally oriented microfibrils are negatively birefringent, that is, the refractive index is maximum for light vibrating perpendicular to microfibril length. Both the X-ray diagram (Fig. 1) and this negative birefringence suggest that the molecular chains in these xylan microfibrils are arranged helically. Since the crystalline component of the walls of all the algae in this group is β-1,3-linked xylan then the same considerations must apply to all of them and, indeed, wall sections are always negatively birefringent. It is not therefore safe to carry over principles which apply to cellulose walls, by assuming that the major extinction position defines the microfibril direction, as has recently been done for *Bryopsis*[17]; though in *Bryopsis* itself the situation is complicated by the fact that extraction of the wall with alkali may reverse the sign of birefringence of the wall as seen in face view (but not, oddly enough, in optical section).

Since whole-wall hydrolysates of these walls contain xylose and glucose with little trace of other sugars, glucans are here prominent among the incrusting substances. These glucans are known to be also β-13,-linked[15,16].

On the other hand, as pointed out by Iriki and Miwa[18], wall hydrolysates of *Codium*, *Acetabularia* and *Halicoryne* (again all members of the Siphonales), treated successively with dilute solutions of sodium hydroxide, sulphuric acid and sodium chlorite, reveal mannose as the main constituent of the preparations. This substantiates our own independent findings on *Codium*, *Acetabularia*, *Dasycladus* and *Batophora* inasmuch as mannose is by far the most abundant sugar in hydrolysates of the whole walls though, in the water extract, galactose and glucose residues occur with the mannose residues. Glucose remains present in trace amounts throughout all stages of Jermyn and Isherwood's[5] extraction, including 24 per cent alkali. This sugar cannot therefore be a contaminant derived from starch, but must form a small but perhaps significant part of the wall organization. Walls of all these plants yield good X-ray diagrams of mannan (Table 1) except in *Codium*, where the reflexions are very diffuse unless incrusting substances have been removed. The inner parts of the relatively large central siphons of *Batophora* plants, which in face-view are strongly positively birefringent, yield an X-ray diagram which shows true orientation, indicating that the crystallites lie longitudinally in agreement with the birefringence. When examined with the X-ray beam parallel to the flattened faces of the wall and perpendicular to the length of the siphon, an even more beautiful diagram is obtained, as illustrated in Fig. 3. This is, so far as we know, the first oriented diagram of mannan to be pub-

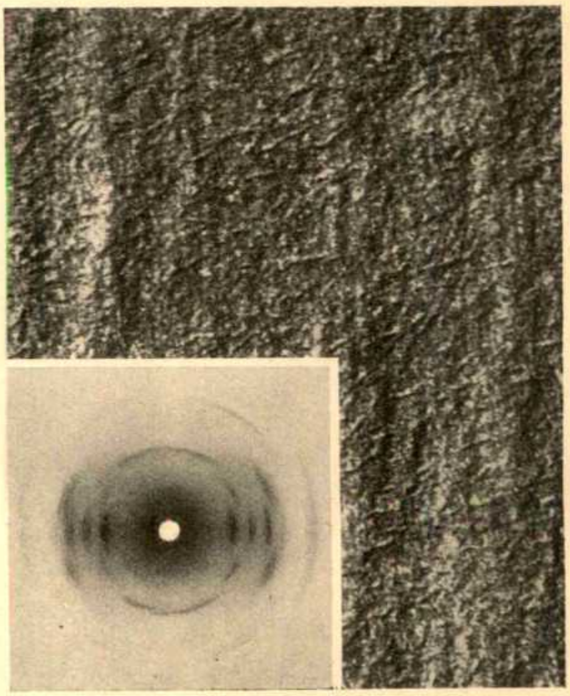

Fig. 3 Fig. 4

lished. The corresponding spacings are listed in Table 1 in comparison with those in the β-1,4-linked mannan of higher plants.

It is difficult to be certain of the form of the skeletal substance in these 'mannan weeds' as seen in the electron microscope, though the indications are that the mannan here consists of short fibrillar bodies of the order of 50 Å. in diameter (Fig. 4). In these walls, which contain no cellulose, we have been unable to find any true microfibrils such as are claimed to exist for the mannan in some higher plants[19]. This may be associated with short chain-length[18]. With all these mannan walls it is of interest to note that material treated with stronger alkali solutions (12–24 per cent potassium hydroxide) yield an X-ray diagram which is not that of the original mannan.

Now that it is established that xylan and mannan can individually form both the major fraction and the only crystalline component of cell walls, we have found it possible to resolve the condition in the red alga *Porphyra* (Bangiales) which has puzzled us for some time. The X-ray diagram of whole fronds of this plant (after chemical pre-treatment) is substantially that of mannan but shows additional reflexions of long spacing. This diagram turns out to be a composite one derived from both the cell walls proper and from a continuous surface sheath, a 'cuticle'. When cell walls alone are examined (as they may be *inter alia* with the rhizoids) the X-ray diagram is the same as those of the group discussed above in which the skeletal material is β-1,3-linked xylan. The corresponding spacings, listed in Table 1, are again unchanged after extraction of the material by boiling water, by chlorination and dilute alkali. The 'cuticle', on the other hand, yields an X-ray diagram of mannan. Both these diagrams conform with the fact that, after extraction of incrusting substances (which contain a range of sugar residues[2]) the cell walls hydrolyse to give xylose and the 'cuticle' to give mannose, each with small amounts of glucose. Cell wall hydrolysates contain no mannose and 'cuticle' hydrolysates no xylose. When chemically extracted cell walls are treated in a homogenizer, the homogenate can be seen in the electron microscope to contain a network of microfibrils indistinguishable from those found in, for example, the primary cell walls of higher plants. 'Cuticles' prepared in the same way show a granular structure. As in the mannan walls, the X-ray diagram of the 'cuticle' after treatment with stronger alkali solutions is not that of the original mannan.

Thus with *Porphyra* we find the odd circumstance that in different parts of the same plant xylose and mannose are used individually in the construction of the skeletal substance. For once the term 'cuticle', used loosely to describe the surface layer of many algae, has real meaning.

Cellulose no longer occupies a unique place as the skeletal substance in cell wall constitution as it was at one time thought to do. Even in the algae considered here, few indeed compared with the large groups which still await attention, we meet some forms in which the sole skeletal substance is a xylan and others in which mannan either forms the only crystalline material or (in *Hydrodictyon*) co-operates with a glucan in a wall which can be defined neither as a cellulose nor a mannan wall. These may be put alongside the greater number of algae in the walls of which the microfibrils, while certainly to be called cellulosic, nevertheless contain high proportions of xylan and the extreme case of the algae in Group 1 of Nicolai and Preston[1] in which the cellulose is pure. In all these forms, without any exception so far, some glucose at least is present in the skeletal material. Both cellulose and mannan are β-1,4-linked as is also xylan, according to X-ray evidence, when it is present in a cellulosic wall. The only skeletal xylan so far found, however, is β-1,3-linked, and it would seem to be significant that the glucans associated with it are also β-1,3-linked[15,16]. The situation in *Halicystis* appears to be an exception.

There is still some question whether the non-cellulosic skeletal substances form true microfibrils in the sense of the individual, easily separable bodies formed by cellulose. Even with the 'xylan weeds', what appear to be microfibrils cannot be separated, and torn edges of the wall never show the fringe of loose microfibrils typical of cellulose walls. This suggests that xylan microfibrils are interlinked. In the 'mannan weeds', separation of the wall into skeletal and incrusting substances seems pointless at the moment since here no microfibrils have yet been found. This fact, together with the observation that the walls of 'mannan weeds' are still coherent after treatment with strong alkali which leaves the only crystalline material in the form of granules, suggests that the role of microfibrils in strengthening a wall may have been over-emphasized.

The relative amount of skeletal material found in algal cells walls is in this respect not without interest. In the algae of Group 1, in which the skeletal material is pure cellulose, the microfibrillar component makes up between 30 and 75 per cent of the wall weight, a range which covers also most of the (cellulosic) secondary walls of higher plants. A somewhat similar figure holds also for the 'xylan weeds' ($\geqslant$ 50 per cent). With 'mannan weeds' the walls of which contain up to 90 per cent of mannose residues, no figure can be given on account of the difficulty of defining the skeletal component. In the remainder of the algae so far investigated, in which the microfibrils probably consist of a cellulose core with a hemicellulose cortex[6], the relative amount of skeletal material is low (2–20 per cent). All these walls are equally coherent whatever the proportion of the skeletal material.

Nicolai and Preston[1] made no mistake in concluding that among the Chlorophyceae variations occur in the construction of cell walls, though the basis on which their conclusions were founded was not completely reliable. Our newer observations show that while the bulk of the algae contain cellulose I, including most of those which Nicolai and Preston placed in Group 2, some make use for the same purpose of long-chain polymers built from sugars other than glucose. It is surely significant that this latter condition is almost exclusively confined to the Chlorophyceae. No plant so far investigated, with the exception of one (dubious) case, *Halicystis*, has been found to contain cellulose II. The algae of Group 1 still stand as unique among plants; the attempt to classify the rest of the algae into two groups must, however, be abandoned, and no new grouping is justified at this stage, particularly in view of complex forms like *Halicystis* and *Porphyra*.

For part of this investigation we received material from: Dr. R. P. Bengry, Institute of Jamaica; Dr. P. B. Tomlinson, Fairchild Tropical Garden, Florida; Dr. W. Eifion Jones, Marine Biological Station, Bangor; and Miss J. M. Kain, Marine

Biological Station, Port Erin To all of them our thanks are due

PRODUCTION AND PROPERTIES OF DI-FLUOROCARBENE

By Dr J P. SIMONS and A J YARWOOD
Chemistry Department, University of Birmingham

THE di-fluorocarbene molecule, CF_2, was first detected spectroscopically in 1950, when its emission[1] and absorption[2] spectra in the ultra-violet region were photographed following the decomposition of fluorocarbon vapours in an electrical discharge The observation that, provided the containing vessel were large enough, the absorption spectrum could still be detected seconds after the discharge was discontinued[2] was striking. it was inferred that CF_2 was a remarkably stable species, and that it disappeared after diffusion to the wall of the vessel

Since 1950, CF_2 has been produced (and detected spectroscopically) by such a variety of methods that it is now apparent that its formation must be a favoured process Table 1 lists some parent molecules which have been used and the methods of decomposition adopted A zero order for the rate of disappearance of CF_2 produced in flash photolysis has been reported, and its long life-time confirmed[3]

Table 1

Parent molecule	Method	Reference
Fluoro-carbons	Elec discharge	1, 2
CF_4	Furnace	4
CF_3COCF_3	Flash photolysis	5
CF_2Br_2	,, ,,	6
CF_2HBr	,, ,,	7
$CF_2ClCOCF_2Cl$	,, ,,	3
$CF_2\,CF_2$	,, ,,	8
CF_3COOH	,, ,	8

It has been suggested[9] that the production of CF_2 in the flash photolysis of hexa-fluoroacetone might follow the disproportionation

$$2CF_3 \rightarrow CF_4 + CF_2$$

However, when the photolysis of CF_3I is used as a source of CF_3 radicals, no CF_4 can be detected among the volatile reaction products although there is an abundance of C_2F_6 (ref 10) Further, although flash photolysis of CF_2Br_2 and CF_2HBr in the quartz ultra-violet region produces a high yield of CF_2, no CF_2 absorption could be detected following the flash photolysis of CF_3I (ref 11) and CF_3Br (ref 8) under the same conditions Indeed, only when the latter molecules were photolysed in a specially constructed flash discharge cell which was transparent to wave-lengths well below 2000 Å (see Fig 1) was it possible to observe a faint absorption spectrum of CF_2 It follows that a far greater energy input is required to obtain CF_2 from CF_3Br than from CF_2Br_2 or CF_2HBr, although the C—Br bond dissociation energies in the molecules would not differ very greatly. If the CF_2 production occurs through the disproportionation of substituted methyl radicals, then it is hard to understand why the disproportionation of CF_2Br and CF_2H should be so favoured as compared with CF_3

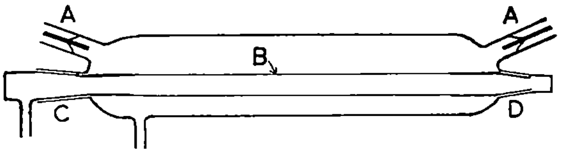

Fig 1 Silica cell for flash photolysis at wave-lengths < 2000 Å (Drawing not to scale) *A*, Electrodes, *B*, thin silica (thickness 0 5 mm), *C*, socket and cone, *B* 19, *D*, socket and cone, *B* 14

Finally, we have found that if CF_2Br_2 is flashed (under conventional conditions) in the gas phase in the presence of a large excess of oxygen, very few bromine atoms are produced, since the expected absorption spectrum of the BrO radical is barely detectable (Flash photolysis of CCl_2Br_2 under the same conditions resulted in a very intense transient spectrum of BrO) In particular, the yield of CF_2 is virtually independent of the oxygen pressure, which must exclude CF_2Br radicals as the precursors to CF_2 formation

The data presented are all consistent with the primary production of CF_2 in a molecular split, as.

$$CF_2Br_2 + h\nu \rightarrow CF_2 + Br_2$$
$$CF_2HBr + h\nu \rightarrow CF_2 + HBr$$
$$CF_3COCF_3 + h\nu \rightarrow CF_2 + CF_3COF$$

and so on A similar primary decomposition has been proposed in the xenon photosensitized decomposition of CF_4 (ref 12) Such modes of decomposition are not in conflict with the suggestion that CF_2 is a relatively stable species having the properties of a two-electron deficient molecule rather than a di-radical This hypothesis is favoured by (1) the observation of an intense absorption spectrum of CF_2 following flash photolysis of tetra-fluoroethylene in the gas phase[8], which demonstrates the relative weakness of the carbon–carbon bonding in the olefine, (2) the lack of reactivity of CF_2 towards molecular oxygen, and (3) its zero-order rate of decay, demonstrating its lack of reactivity to other molecules of the same kind

The difficulty in forming CF_2 following photolysis of CF_3Br is understandable in view of the energetics of the decomposition

$$CF_3Br \rightarrow CF_2 + BrF$$

Such difficulty would not be anticipated in the cases of CF_2Br_2 and CF_2HBr, since in the first case both the bonds broken are weak, and in the second there is a considerable energy 'rebate' in the formation of the HBr molecule.

The ready decomposition of tetra-fluoroethylene into two CF_2 molecules, taken together with the other experimental results presented, suggests that in the fluorocarbon series it is not unreasonable to regard di-fluorocarbene as the simplest of the olefines. The splitting out of CF_2 from the substituted methanes and ketones listed is then analogous to the production of ethylene from ethyl iodide[13], and the Norrish Type II split in ketones containing hydrogen. Indeed, it has been proposed very recently[14] that the primary steps in the pyrolysis of hexa-fluoroacetone include the molecular decomposition

$$CF_3COCF_3 \rightarrow CF_2 + CF_3COF$$

as well as the radical decomposition

$$CF_3COCF_3 \rightarrow 2CF_3 + CO$$

The striking stability and the lack of chemical reactivity in di-fluorocarbene may be attributed, no doubt, to the influence of the strongly electronegative fluorine atoms. These would tend to attract the two electrons residing in the most weakly bound of the molecular orbitals, away from the neighbourhood of the carbon atom, on which they would otherwise be localized. As a result, the possibility of electron exchange interaction with other species would be much reduced, since there would be less possibility of electron overlap. This effect would not be anticipated in other di-halogenocarbenes, such as CCl_2 and CBr_2, since the electronegativities of Cl and Br atoms are not so very different from that of carbon. On Pauling's electronegativity scale, F = 4.0, Cl = 3.0, Br = 2.8 and C = 2.5. Indeed, attempts to prepare CCl_2 and CBr_2 photochemically from parent molecules analogous with those used for CF_2 production have so far proved unsuccessful[7].

One of us (A. J. Y.) thanks the Department of Scientific and Industrial Research for the award of a maintenance grant.

ACTION OF RADIATION ON SYNTHESIS OF DEOXYRIBONUCLEIC ACID IN NORMAL AND TUMOUR STRAIN CELLS

By Dr. JOHN SEED

Department of Radiotherapeutics, University of Cambridge

HOWARD and Pelc[1,2] first showed that relatively small doses of radiation (50–200 r.) given during the deoxyribonucleic acid (DNA) pre-synthetic period, delayed the entry of cells into DNA synthesis, whereas cells already in DNA synthesis at the time of irradiation were unaffected by the doses given. These authors used phosphorus-32 uptake into DNA of bean root cells, and examined by autoradiography the number of cells synthesizing DNA over short periods up to 24 hr. during the interphase following irradiation. Holmes and Mee[3] and Kelly *et al.*[4], using regenerating liver and uptake of phosphorus-32 into DNA, again found that radiation doses of about 300 r. given during the pre-synthetic period delayed the onset of DNA synthesis; much larger doses (~2,000 r.) were required to depress DNA synthesis once it had commenced.

Lajtha *et al.*[5] found that doses of ~ 200 r. given to human bone marrow cells in culture during the pre-synthetic period delayed the entry of cells into DNA synthesis; the incorporation of ^{14}C-formate into DNA was observed by autoradiographic methods after various fractions of the interphase period following irradiation. On the other hand, it was found that a dose of 2,000–5,000 r. was required to reduce the rate of DNA synthesis to half, in cells which were already in synthesis.

In considering the effects of radiation on solid tumours *in vivo*, it is difficult to dissociate direct effects on the tumour from indirect effects acting through the surrounding host tissues[6]. In addition one such tumour usually represents a great variety of cell types; one way out of this difficulty is to use a tumour strain growing *in vitro*, and another possibility is to use an ascites tumour.

Painter and Robertson[7] used HeLa carcinoma strain cells in culture in conjunction with thymidine uptake and autoradiography, and found an increase in the number of cells in DNA synthesis at times up to 8 hr. after 500 r. of X-irradiation, and a decrease in the number of synthesizing cells after 17 hr. These results could partly be explained by inhibition of mitosis; first, an increase by retention in synthesis of cells which would normally have divided and, later, a decrease from the consequent depletion of mitosis; first, an increase by retention in synthesis. Robertson pointed out, the results are certainly inconsistent with a delay in onset of DNA synthesis induced by radiation in the pre-synthetic period[7]. Again, using HeLa cells with thymidine and autoradiography, Yamada and Puck[8] found that radiation doses of 34–135 rads produced mitotic inhibition, but not a delay in the onset of DNA synthesis in these cells; this was in contrast with their findings with normal human cells in culture which showed a pre-synthetic delay in addition to inhibition of mitosis.

Dickson, Paul and Davidson[9] used *L* mouse strain cells in culture in conjunction with incorporation of ^{14}C-formate into DNA. These authors concluded that the effect of X-irradiation (800 r.) was to inhibit division the total amounts of cell constituents were found to be almost the same in the irradiated cultures as in the controls, and no alteration of ^{14}C-formate incorporation into DNA bases could be detected at times up to 24 hr. (more than one interphase period) after a dose of 800 r. to the cultures.

Kelly *et al.*[10] irradiated Ehrlich ascites tumour cells with a dose of 800 r. and investigated subsequent DNA synthesis by uptake of phosphorus-32 into DNA, and also by Feulgen staining combined with photometry. These authors found that the uptake of phosphorus-32 into DNA remained unaffected until 20 hr. after irradiation, at which time the average DNA content per cell was found to have increased; after 20 hr., a decrease in uptake of phosphorus-32 was observed, because, according to these authors, the cells were prevented from going through mitosis by the irradiation dose given.

The purpose of this article is to point out that those experiments which have shown inhibition of the onset of DNA synthesis with radiation doses of the order of a few hundred rœntgens in the pre-synthetic period have used cells freshly prepared from normal tissues, whereas those experiments using similar radiation doses which have failed to show an effect on the onset of DNA synthesis in the pre-synthetic period have used tumour-strain cells.

In order to explain their radiation results, it has been suggested by Lajtha *et al.*[5] that in human bone marrow cells there exists a 'trigger mechanism' connected with the onset of DNA synthesis, which is more sensitive to radiation than the process of DNA synthesis itself. Because of the results reviewed above, it would seem that this applies to the normal cells but not to the tumour strains.

It was reported some years ago that an increase in ultra-violet absorption by the cytoplasm occurred in irradiated cells[11]. More recently it has been shown[12-14] that an accumulation of soluble deoxy-derivatives, including deoxyribonucleoside triphosphates, occurred in irradiated thymus; these results were interpreted as indicating that inhibition of DNA synthesis by radiation was not caused by lack of precursors, but by failure of polymerization or breakdown in energy-generating mechanisms in the nucleus[14]. In this connexion, Creasey and Stocken[15] found that nuclear phosphorylation of purine and pyrimidine monophosphates to triphosphates is completely inhibited by 100 r. and reduced by 50–80 per cent after 25 r. In addition, in regenerating liver an increase in thymidine kinase and DNA polymerase is stopped by irradiation in the early pre-synthetic period, but not by irradiation in the DNA synthetic period[16].

Recently it has been shown by me[17] that, in three types of freshly prepared normal cells grown in culture (monkey kidney, embryo human, embryo mouse), the processes of DNA and nuclear protein synthesis are initiated together after the same waiting time (the pre-synthetic period) has elapsed, and thereafter the syntheses proceed approximately together. However, in the continuous tumour strains HeLa and *L* mouse, it was found that nuclear protein synthesis proceeds continuously during interphase and its onset does not await the onset of DNA synthesis, which commences after a waiting time has elapsed as in other types of cells[17]. Supporting evidence for this time-disconnexion of nuclear protein and DNA synthesis in tumour strains comes from the distributions of DNA and dry mass values found in Krebs ascites tumour cells[18]. Because of the genetic role at present ascribed to DNA, I have suggested[17] that the difference in timing of the onset of nuclear protein synthesis reflects a fundamental difference in metabolism between normal and tumour strain cells. It would appear from the radiation work reviewed here[1-10], that the processes responsible for initiation of DNA synthesis in these cells are also different in character.

Allfrey *et al.*[19,20] found that, in isolated calf thymus nuclei, the incorporation of amino-acid into protein required the presence of DNA, and that one role of DNA was in the production of adenosine triphosphate. Inhibitors of ATP synthesis were found to inhibit incorporation of amino-acid[20], and also the addition of histones to the nuclei was found to inhibit strongly respiration and nuclear phosphorylation[21]. Davison and Butler[22] and Vendrely *et al.*[23] reported that the total amount of all the basic groups in the nucleohistone is approximately equal to the total amount of phosphate in the DNA.

It may therefore be permissible to suggest here that the simultaneous initiation of DNA and nuclear protein syntheses in normal cells[17] might reflect a mutual control system which would operate by regulating nuclear phosphorylation processes. The time-disconnexion of DNA and nuclear protein syntheses found in tumour strains[17,18] would imply dislocation of control of phosphorylation and would be consistent with the lack of radiosensitivity found in the DNA pre-synthetic period with these cells[7-10]. It is worth noting that Paul *et al.*[24] were unable to find evidence of any consistent radiation-induced depression of thymidine incorporation into thymidine triphosphate in either *L* mouse strain cells or in a lymphosarcoma cell strain, in contrast with the radiosensitivity of phosphorylation processes found in thymus nuclei[15].

This work was carried out while I was holder of the Royal Society Foulerton Gift Research Fellowship.

SUBSTRATE SPECIFICITY AND INHIBITION OF NICOTINAMIDE MONONUCLEOTIDE-ADENYLYL TRANSFERASE OF LIVER NUCLEI: POSSIBLE MECHANISM OF EFFECT OF 6-MERCAPTOPURINE ON TUMOUR GROWTH

By DR M R ATKINSON, J. F. JACKSON and PROF R K. MORTON

Department of Agricultural Chemistry, Waite Agricultural Research Institute,
University of Adelaide

SYNTHESIS of nicotinamide adenine dinucleotides (coenzymes I and II) in most animal tissues involves formation of dinucleotide in the cell nucleus[1,2] catalysed by nicotinamide mononucleotide–adenylyl transferase (formerly known as coenzyme I-pyrophosphorylase)[3], thus

nicotinamide mononucleotide + adenosine triphosphate ⇌ nicotinamide adenine dinucleotide + pyrophosphate

The biological significance of this reaction, which was discovered by Kornberg[4], has been discussed by Branster and Morton[2], and by Morton[5]. The work described here was carried out with enzyme obtained from isolated pig-liver nuclei[6], either purified (specific activity approx 3) or partly purified enzyme (specific activity, 0 7–1 μmole of nicotinamide adenine dinucleotide formed/min /mgm of protein at 37° C, *p*H 7 6) was used

Substrate specificity In work on dinucleotide synthesis, the reaction mixture (0 2 ml, *p*H 7 6) contained approximately 0 005 unit[6] of enzyme, 25 μmoles of glycylglycine, 3 7 μmoles of magnesium chloride, 1 μmole of adenosine triphosphate (Sigma Chemical Co, U S A, for purity, see ref 7) and approximately 1 μmole of nicotinamide mononucleotide[6], analogues replaced adenosine triphosphate or nicotinamide mononucleotide, as appropriate In work on pyrophosphorolysis of dinucleotides, the reaction mixture (0 2 ml, *p*H 7 6) contained similar amounts of enzyme, buffer and magnesium salts, 20 μmoles of pyrophosphate and 1 μmole of nicotinamide adenine dinucleotide or of appropriate analogue After incubation for 2½ hr at 37° C, an appropriate portion (0 02–0 05 ml) of the reaction mixture was applied to strips of filter paper (Whatman, 3 *MM*), nucleotides were separated by electrophoresis in 0 04 *M* sodium citrate, *p*H 4 2 for 3¼ hr at 400 V (approximately 14 V per cm) and detected by printing on reflex document paper with ultra-violet light[7] Quaternary nicotinamide compounds were detected by fluorescence after exposure to an atmosphere of methylethylketone–ammonia[8]

Table 1 shows the reactions investigated and the results obtained It was previously shown[9] that the α-anomer of nicotinamide mononucleotide is not a substrate of the enzyme, which is almost certainly specific towards the β-*N*-glycoside bond The pyridine mononucleotide (Table 1, reaction 7) probably contained both α- and β-anomers, but the proportions of these is not known, although unlikely, it is possible that the absence of a detectable reaction with this compound is due to a predominance of the α-anomer

A number of purine riboside triphosphates, in addition to adenosine triphosphate, act as nucleotidylyl donors to nicotinamide mononucleotide (Table 1) Of the dinucleotides so formed, only nicotinamide hypoxanthine dinucleotide has previously been described[11] Nicotinamide guanine dinucleotide was separated from the reaction products (Table 1, reaction 9) by chromatography on 'Dowex-2' formate with a gradient of formic acid, the dinucleotide was eluted between 1 and 1 5 *N* formic acid The properties of the dinucleotide are shown in Table 2

Table 1 shows that no enzymatic reaction could be detected with dinucleotides containing analogues of both nicotinamide and of adenine (such as 3-acetyl-pyridine hypoxanthine dinucleotide) With enzyme preparations obtained from acetone powders of pig-

liver[4], Kornberg[4] earlier demonstrated reaction 3, and Preiss and Handler[14] reaction 2 of Table 1, Klenow and Andersen[15] previously demonstrated reaction 12 (Table 1) with an enzyme preparation from yeast[4]

Inhibition of synthesis of nicotinamide adenine dinucleotide Kinetic work was carried out at *p*H 7 4–7 6, the reaction mixtures contained at appropriate concentrations, enzyme, glycylglycine, adenosine triphosphate, nicotinamide mononucleotide, magnesium chloride, and inhibitor After incubation for 5 min at 37° C, the reaction was stopped with trichloroacetic acid and the amount of nicotinamide adenine dinucleotide was estimated enzymically[6] Determinations were made with several concentrations of inhibitor for each of two or more concentrations of the appropriate substrate (nicotinamide mononucleotide or adenosine triphosphate) Values of K_i (see Dixon and Webb[16], p 22 *et seq*) were estimated graphically In studies with hypoxanthosine triphosphate (inosine triphosphate), the concentration of magnesium chloride was twice that of the total concentration of the nucleoside triphosphate present in each reaction mixture

Values of K_m for several substrates were estimated similarly except that the rate of formation of nicotinic acid adenine dinucleotide was measured by estimation of pyrophosphate

With hypoxanthosine triphosphate and nicotinic acid mononucleotide, inhibition of adenylyl transfer was competitive, Table 3 shows the K_i values for these compounds as inhibitors, and also the K_m values for these compounds when used as substrates for the enzyme

Table 3 INHIBITOR CONSTANT (K_i) AND MICHAELIS CONSTANT (K_m) FOR SOME COMPETITIVE INHIBITORS OF SYNTHESIS OF NICOTINAMIDE ADENINE DINUCLEOTIDE (COENZYME I)

All values were determined at *p*H 7 4–7 6, and at 37° C

	Substrate*	Inhibitor	K_m (m*M*)	K_i† (m*M*)
1	Adenosine triphosphate		0 4	—
2	Hypoxanthosine triphosphate		1 8	—
3	Adenosine triphosphate	hypoxanthosine triphosphate	—	2 1
4	Nicotinamide mononucleotide		0 12	—
5	Nicotinic acid mononucleotide		0 4	—
6	Nicotinamide mononucleotide	nicotinic acid mononucleotide	—	0 38

* For 1–3, the co-substrate was nicotinamide mononucleotide, for 4–6, adenosine triphosphate

† See Dixon and Webb (ref 16, p 22)

6-Mercaptopurine riboside (Sigma Chemical Co, U S A) was converted to the corresponding 5′-monophosphate, which was treated with orthophosphate and dicyclohexylcarbodiimide to obtain the nucleoside triphosphate[17] The nucleotide products were adsorbed on to charcoal, and then washed, eluted and dried *in vacuo* (preparation *A*) Preparation *A* contained components which appeared to be the 5′-mono-, di- and tri-phosphates of 6-mercaptopurine riboside, since they migrated similarly to hypoxanthosine-5′-mono-, di- and tri-phosphates on paper electrophoresis Chromatography of preparation *A* on Ecteola' resin[17] gave four fractions, of which the last to be eluted (preparation *B*) was probably the 6-mercaptopurine riboside 5′-triphosphate, however, it was obtained in very low yield and in insufficient amount for chemical characterization

Adenylyl transfer to nicotinamide mononucleotide was inhibited competitively by both preparations *A* and *B* Separately, it was found that the 6-mercaptopurine itself, the riboside, and corresponding riboside 5′-phosphate do not inhibit adenylyl transfer at concentrations up to the concentration of the total 6-mercaptopurine nucleotide in preparation *A*

With preparation *A* and nicotinamide mononucleotide as substrates, nicotinamide 6-mercaptopurine dinucleotide was formed (Table 1), confirming that preparation *A* contained 6-mercaptopurine riboside triphosphate

From the kinetics of the competitive inhibition of adenylyl transfer by preparation *A*, and assuming that the only inhibitory material in preparation *A* was 6-mercaptopurine riboside triphosphate, K_i would be 0 3 m*M* if the yield of triphosphate were similar to that reported by Parks and co-workers[17]. Final K_i and K_m values for 6-mercaptopurine riboside triphosphate await preparation of larger amounts of material and adequate chemical characterization of the triphosphate

Possible mechanism of the selective cytotoxic effect of 6-mercaptopurine against tumours Branster and Morton[2] found that the activity per nucleus of the nicotinamide mononucleotide–adenylyl transferase of a number of tumours is considerably less than that of comparable normal tissues, the concentration of nicotinamide nucleotide coenzymes (coenzymes I and II) per nucleus (or per cell) is also considerably lower in tumours than in comparable normal tissues (see ref 5) Morton[5] therefore proposed that inhibition of the nicotinamide mononucleotide–adenylyl transferase of the cell nucleus would lower the level of the nicotinamide coenzymes of tumour cells below that necessary for survival of the tumour, and indicated the general characteristics required for a physiologically effective inhibitor

6-Mercaptopurine meets some of these criteria[5] for a compound selectively active against tumours. In susceptible cells, it is converted to 6-mercaptopurine riboside 5′-mono-, di- and tri-phosphates[18–20] 6-Mercaptopurine riboside triphosphate is an analogue of adenosine triphosphate and, like hypoxanthosine triphosphate, is a substrate for nicotinamide mononucleotide–adenylyl transferase (Table 1) Although the chemical characterization of the components of preparation *A* is incomplete, the potent inhibition by preparation *A* and preparation *B* is almost certainly due to 6-mercaptopurine riboside triphosphate

The selective toxicity of 6-mercaptopurine against tumour cells thus appears to be due to inhibition of the biosynthesis of nicotinamide nucleotide coenzymes (coenzymes I and II), this inhibition occurs after the enzymic conversion of the purine to the purine riboside triphosphate, which competitively acts on the nicotinamide mononucleotide–adenylyl transferase of the tumour nucleus and effectively limits dinucleotide formation Symptoms similar to those of nicotinamide deficiency have sometimes been observed in patients after prolonged treatment with 6-mercaptopurine[21]

Hypoxanthosine triphosphate is not sufficiently active to be an effective inhibitor of formation of coenzyme I *in vivo* (Table 3) Although nicotinic acid mononucleotide is strongly inhibitory (Table 3), the nicotinic acid adenine dinucleotide formed with substrate-levels of nicotinic acid mononucleotide may afterwards be converted to nicotinamide adenine dinucleotide When nicotinic acid is administered to rats together with nicotinamide, it causes a marked decrease in the rate of formation of nicotinamide adenine dinucleotide in the liver, as compared with rats receiving nicotinamide alone Table 3 shows that this effect is probably due to the inhibition of adenylyl transfer to nicotinamide mononucleotide by nicotinic acid mononucleotide

6-Mercaptopurine was introduced by Hitchings *et al* [22], as a potential antagonist of biosynthesis of nucleic acids, but recent findings[20,23] do not support this explanation of its action against certain human leukæmias and some transplanted tumours of animals Although the evidence presented here shows that 6-mercaptopurine probably acts on tumours via the effect on biosynthesis of nicotinamide nucleotide coenzymes, since 6-mercaptopurine riboside triphosphate is an analogue of adenosine triphosphate, it could possibly influence a wide range of enzymatic reactions The undesirable side-effects of 6-mercaptopurine may be partly associated with such multiple actions Moreover, certain tumours have a limited enzymatic capacity for converting the purine to the nucleotide[20,24] and so escape the lethal depression of coenzyme synthesis It thus seems preferable to inhibit formation of nicotinamide nucleotide coenzymes in tumours via analogues of nicotinamide mononucleotide, as previously suggested[5].

MULTIPLE HÆMOGLOBINS AND TRANSFERRINS IN A MACAQUE SIBSHIP

By PROF J. BUETTNER-JANUSCH, J. B. TWICHELL and BERT YUAN-SHU WONG

Department of Anthropology

Yale University

PHYSICO-CHEMICAL differences between embryonic, fœtal, and adult human hæmoglobins[1–4] and the occurrence of a number of transferrin phenotypes in man[5,6] have led several investigators to examine hæmoglobins and β-globulins in various Primates[7–13]. We report here on the hæmoglobins and β-globulins obtained from a related, inbred group of rhesus macaques (*Macaca mulatta*) Very young macaques have relatively high levels of alkali-resistant hæmoglobins, and the levels decrease as the animals grow older[8] The number of β-globulins reported for macaques (*M mulatta* and *M irus*) has been large[11,12]. The results presented here are consistent with earlier findings on alkali-resistant hæmoglobins[8] and with reports of transferrin polymorphism[11–15] in various Primates However, we

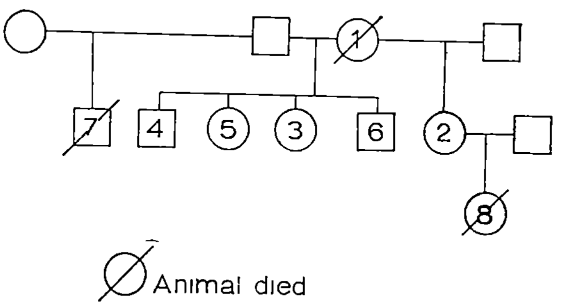

Fig 1 Pedigree of inbred macaque sibship Animal 1 died 14 days *post partum*, animals 7 and 8 were 90-day fœtuses taken by Cæsarean section The symbols which do not contain numbers represent animals not sampled for this work

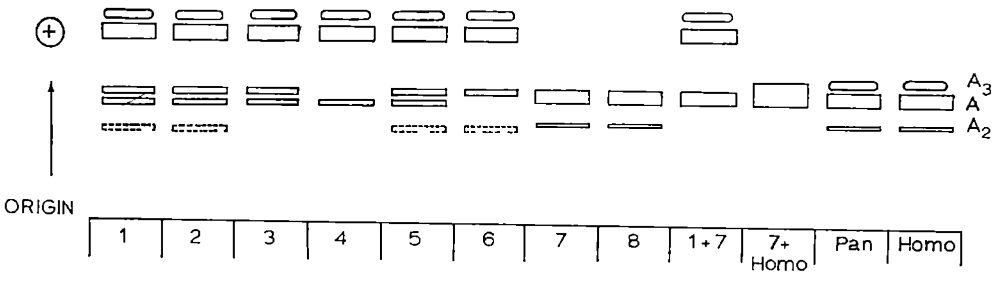

Fig 2 Diagram of a starch-gel after electrophoresis showing multiple hæmoglobins from macaques The human and chimpanzee (*Pan*) samples were run on this gel for comparison A, A_2, and A_3 refer to the known hæmoglobins in this human sample and do not refer to the macaque or chimpanzee samples When hæmoglobin from a fœtus (animal 7) was combined with either adult macaque or human hæmoglobin, the bands were incompletely resolved The bands represented with dotted lines are those which stained weakly with benzidine

find this macaque sibship contains individuals that unequivocally display multiple hæmoglobins

We received cord blood from two 90-day *M mulatta* fœtuses taken by Cæsarean section, and from one of these we obtained blood from the aorta as well Six animals related to the fœtuses in the same sibship were also sampled (Fig 1) In this sibship the normal gestation period is 168 days[16] Blood was drawn into tubes containing citric acid, sodium citrate, and dextrose Serum and cells were separated by centrifugation, and hæmolysates were prepared by the method of Jonxis and Huisman[17]. Alkali-resistant hæmoglobins were demonstrated by the method of Singer *et al* [18] The hæmoglobin components were resolved on horizontal starch-gels, 13 per cent starch in *tris*-citrate buffer at *p*H 8 6 The gels were run for 16 hr. at 6 V /cm. with borate buffer, 0 3 *M*, *p*H 8 6, as the bridge solution[19]. Gels were sliced in half, one section was stained with a benzidine reagent (200 ml of 50 per cent ethanol 0 1 ml. of glacial acetic acid 4 mgm. of benzidine , 0 4 ml. of hydrogen peroxide added immediately before use) The other section of the gel was stained with bromphenol blue or amido-black The β-globulins were resolved and identified on vertical starch-gels by a method previously described[14]

A diagram of a starch-gel electrophoretogram of the hæmoglobin samples is shown in Fig 2 Three of the samples, including the two fœtuses, show two distinct components In three of the samples there are 4 components, and two show 3 components , four of these five samples show an additional component ; this was a very slow-moving band that stained weakly with benzidine In order to obtain better resolution and a confirmation of these results, sample 1 was run for 24 hr. at 10 V /cm The mobility of the principal component was 4–5 times that of human hæmoglobin *A* on the same gel The several components seen in these animals have not been reported in other work on macaque hæmoglobins Our previous experience and that of other investigators[20] with macaque hæmoglobins showed that only the single component reported by Sen *et al* [8] appeared There is one report that agar-gel electrophoresis demonstrated differences between the cord blood of a new-born macaque and its mother , a second component was found in the cord blood of this new-born animal[7] In addition, Lie-Injo *et al* [10] and Tuttle *et al* [9], using paper electrophoresis and veronal buffers, demonstrated other components in the hæmoglobins of macaques They were able to resolve only 2 components in individual animals , we can show as many as 5 components in one of our animals, and all the animals in this sibship have at least 2 hæmoglobins

The transferrins of these animals are illustrated in Fig 3 The diagram shows the bands which appeared on the autoradiographs of the starch-gels in which the sera were run The half-gel which was stained with amido-black is illustrated in Fig. 4 It is clear to us that some of the bands in the β-globulin region on these gels are indeed transferrins In the fœtal sera (animals 7 and 8) there are two distinct bands of protein in the β-region which stain faintly with amido-black but do not appear on autoradiographs Their position corresponds to the 2–3 iron-binding bands in some of the adult sera However, it was not possible to demonstrate iron-binding by these bands in the samples from the cord or the aorta of the two fœtuses. In general, we accept as transferrin only those bands which clearly take up radioactive iron-59. This criterion must be applied with care, since it is possible that these iron-binding proteins are saturated *in vivo* at the time the blood is drawn[21] We have named the transferrin types according to the mobility of the iron-binding bands Thus, a 1–1 or a 2–2 type is a macaque with only one such band, and a 1-1 type has the most mobile band , a 2–3 type is an animal that has two iron-binding bands, the second and third in order of decreasing mobility

Tables 1 and 2 summarize the results obtained for the 8 samples under discussion here. It is important to note that the proportion of alkali-resistant hæmo-

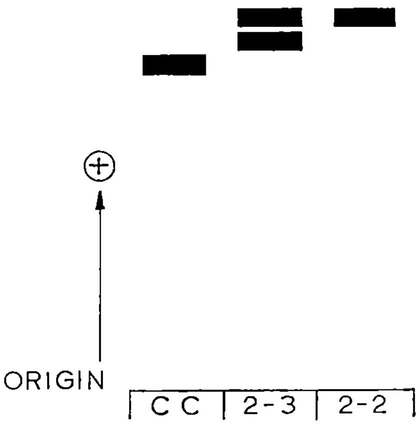

Fig 3. Diagram of autoradiographs showing transferrin types of 8 animals in the macaque sibship Three of the animals are type 2–2, 5, including the two fœtuses are type 2–3 A human homozygous CC phenotype is shown for comparison

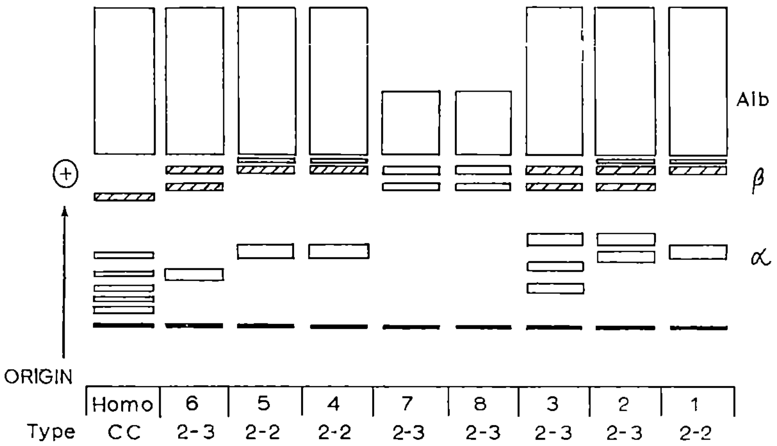

Fig 4 Diagram of a starch-gel electrophoretogram showing those bands which stained with amido-black Albumin, α- and β-globulin regions are noted In the β-region the hatched bands are those which show uptake of iron-59 on autoradiographs A human sample, run on the same gel, is for comparison

globin is very high in the samples from the 90-day fœtuses By the time an animal is one year old (animal 5) the level has dropped markedly In 4 of the 5 adult animals we were unable to demonstrate any alkali-resistant pigment, and in the fifth the amount was negligible. The ultra-violet absorption spectrum of the alkali-resistant hæmoglobin from a fœtal sample (animal 7) was identical with published spectra of alkali-resistant fractions prepared from human hæmoglobin[18]

The hæmoglobin components seem to be inherited as simple autosomal alleles The major problem here, as with human hæmoglobin *A* and A_2, is whether there are two loci involved or whether these hæmoglobins are allelic at the same locus It seems clear that the principal component (that producing the densest stain and the largest spot) and one analogous to A_2 (human) will prove to be inherited as simple autosomal traits The third component we definitely demonstrate may be analogous to human *F*, since it and the major band in macaque fœtuses correspond In the adult animal, it is a slow-moving band We found no alkali-resistant hæmoglobin in these adults, hence the analogy with human hæmoglobin may not hold The samples taken from the two fœtuses were so small that only alkali-denaturation studies and electrophoresis on starch-gels were possible

Table 1. HÆMOGLOBINS AND TRANSFERRINS

Animal	No. of hæmoglobins	Transferrin type
1	4 (5)	2-2
2	4 (5)	2-3
3	3 (4)	2-3
4	3	2-2
5	4 (5)	2-2
6	3 (4)	2-3
7	2	2-3 (?)
8	2	2-3 (?)

Table 2. ALKALI-RESISTANT HÆMOGLOBIN

Animal	Age	Sex	Alkali-resistant hæmoglobin (per cent)
1	Adult	♀	0
2	Adult	♀	1 2
3	2 years	♀	0
4	4 years	♂	0
5	1 year	♀	0
6	14 days	♂	50 0
7	Fœtus	♂	85 7 (cord)
8	Fœtus	♀	78 3 (cord) 75 6 (aorta)

The nomenclature used for the transferrin types implies that the inheritance of these β-globulins is due to simple non-dominant alleles, as is the case for the human transferrins[5] The pedigree (Fig 1) bears this out, but samples from the missing animals are necessary to demonstrate this conclusively

Sufficient data[11,12] have been reported so that it is reasonable to predict that transferrin polymorphism exhibited by macaques may be due to the action of natural selection on different populations of these animals Unfortunately, it is not possible to work out the inheritance of many of these transferrins until various different phenotypes have been cross-bred The number of hæmoglobins may not be explained so simply Our experience with a large number of macaque samples from animals captured in three different localities (India, Malaya, and the Philippines) indicated that no more than two hæmoglobins or components existed The results presented here on a group of related animals demonstrate that multiple hæmoglobins exist and imply that these hæmoglobins are inherited We also have unpublished data indicating that multiple hæmoglobins among the Prosimian Primates is the rule

A final statement about the mode of inheritance of these hæmoglobins cannot be made until additional data become available This problem of multiple hæmoglobins in the non-human Primates is just coming under investigation Thus, we are only starting on an evolutionary and genetic problem of great fascination

This work was supported by grant *RG* 6053 of the U S Public Health Service and a grant from the Department of Anthropology, Yale University, We wish to thank Vina Buettner-Janusch for determining ultra-violet spectra of several samples in a Cary spectrophotometer, model 14 The animals came from the Yale Obstetrics Monkey Colony

EFFECT OF DIETARY ASCORBIC ACID ON THE SILKWORM, *BOMBYX MORI*

By Dr. TOSHIO ITO

Sericultural Experiment Station, Suginami-ku, Tokyo

THERE are a few papers suggesting the importance of ascorbic acid in the nutrition of the silkworm, *Bombyx mori*. Gamo[1] showed that the content of ascorbic acid in fresh mulberry leaves changed in relation to conditions influencing the food value of leaves, and that the amount of ascorbic acid in the larval body is dependent on that in the leaves. According to Murthy[2], ascorbic acid was effective for increasing survival of larvæ. From these papers, however, it may still be impossible to draw a conclusion as to the precise role of ascorbic acid in silkworm nutrition. Ascorbic acid was added to the diet for pink bollworm[3], but most artificial diets developed for other phytophagous insects do not contain ascorbic acid. The failure to rear these insects on such deficient diets has not, so far, been mentioned. On the other hand, Thorsteinson[4] indicated the phagostimulant action of ascorbic acid for several phytophagous insects, and Dadd[5] showed that the inclusion of ascorbic acid in synthetic diet was necessary for normal development to the adult stage in two species of locusts. In locusts, however, ascorbic acid was proved to have negligible effect on the feeding, but was considered to play some part in the processes occurring at the moult. It has long been felt that the role of ascorbic acid in silkworm nutrition, as suggested by previous authors, must be confirmed. The results presented in this article are based largely on observations on feeding responses of silkworm larvæ given ascorbic acid and on its growth-promoting effect, when added to artificial diets for this insect.

For feeding tests an agar diet was used. Its composition was similar in principle to that previously used to test the effect of sugars on silkworm feeding[6]. The diet was composed of agar, starch, sucrose, soybean casein, mulberry leaf powder, and cellulose powder. Twenty ml. water was added to 2.5 gm. of the dry diets. Where necessary, 1 part of soybean oil was added to 12.5 parts of the dry diets, and 30 mgm. of ascorbic acid was contained in 20 ml. of water.

Table 1

	Larval distribution (per cent)
Disk without ascorbic acid	8.5 ± 1.5
Disk with ascorbic acid	83.0 ± 7.2
Filter paper	8.5 ± 7.9

(Five replicates)

Two techniques were used to test the effect of ascorbic acid on feeding behaviour: (1) a two-choice design in which newly hatched, unfed larvæ were allowed to choose the dietary media on which to feed, (previously used by Beck[7] for the European corn borer) and (2) counting the number of fæces produced by newly hatched larvæ. The agar media were cut into disks and placed side by side on the filter paper in a Petri dish. Approximately 25 larvæ were used for each dish and dishes were kept at 25° C. in the dark for a few hours until counts were made on larval distribution resulting from feeding movement. In Table 1 the result on larval distribution is presented. Most of the larvæ (83 per cent) settled on disks containing ascorbic acid, and the remaining small number of larvæ were either on disks without ascorbic acid or on the filter paper. When disks were placed some distance apart, the result was not necessarily clear cut. Later, the newly hatched larvæ, ten in a group, were allowed to feed on the agar diets for 18 hr. at 25° C. At the end of that time, the larvæ were removed from the diet and, with the aid of a magnifying glass, counts were made of the number of fæces. As shown in Table 2, ascorbic acid had a high stimulative action on feeding, irrespective of the presence or absence of added soybean oil, with a high statistical significance. Further, a slight phagostimulant effect of either soybean oil[8,9] or plant sterols[9] was overshadowed by the strong phagostimulant action of ascorbic acid.

Table 2

Ascorbic acid	Soybean oil	Fæces count per larva
−	−	4.3 ± 2.0
+	−	28.3 ± 4.8
−	+	9.4 ± 1.7
+	+	30.2 ± 4.1

(Four replicates)

Since it became evident that ascorbic acid was a strong phagostimulant for the silkworm, an experiment was carried out using artificial diets to assess the effect of dietary ascorbic acid on growth. The diets used for this purpose were not agar-based ones, but culture media solidified with potato starch, as previously used for nutritional work on this insect[8–10]. The following materials were included for basal media: mulberry leaf powder (10 per cent on a basis of dry matter), potato starch, glucose, soybean casein, soybean oil, salt mixture, soybean sterols (or β-sitosterol), vitamin B mixture and cellulose powder. The amount of ascorbic acid to be added ranged from 0.2 to 40.0 mgm. per gm. dry diet. One set of results obtained is presented in Table 3, in which mean body-weight after a 20-day rearing period is shown. Even at a concentration of 0.2 mgm. ascorbic acid per gm. dry diet, good growth was obtained, and the growth was improved by increasing the amount of ascorbic acid in the diets. However, best growth and development were obtained with either 4.0 or 10.0 mgm. per gm. dry diet. Ascorbic acid was also very effective in decreasing the mortality at older larval stages.

Table 3

Ascorbic acid added (mgm./gm. dry diet)	Body-weight of individual after 20-day rearing (mean of 2 batches) (mgm.)
0	49.9
0.2	75.8
1.0	95.5
2.0	132.6
4.0	153.6
10.0	148.9
20.0	111.4
40.0	141.8

Thus ascorbic acid is necessary for better growth and development of the silkworm and should be added to artificial diets as an essential component, as in the locust[11]. The effects of ascorbic acid seem possibly to be due to its phagostimulant action. However, there is a possibility that the growth-promoting effect might be a combined one of those on feeding and nutrition. Further work is necessary on the physiology of ascorbic acid in the silkworm.

The details of this report will be published in the *Bulletin of the Sericultural Experiment Station*.

VENTURICIDIN: A NEW ANTIFUNGAL ANTIBIOTIC OF POTENTIAL USE IN AGRICULTURE

By A. RHODES, K. H. FANTES, B. BOOTHROYD, MOIRA P. McGONAGLE and R. CROSSE

Glaxo Laboratories Ltd., Sefton Park, Stoke Poges, Bucks.

DURING 1957–58 we screened some 8,000 soil actinomycetes for ability to produce new antibiotics active against apple scab (*Venturia inaequalis*). Here we summarize work which terminated in the isolation and biological evaluation of a new antibiotic, 'venturicidin', now being investigated for use in agriculture.

Isolation from Soils

Actinomycetes were isolated by inoculating serial dilutions, from a suspension of soil in water, into agar media containing different carbon sources. After one week's incubation, the 'pin-head' colonies were transferred to potato-dextrose agar slopes in small cylindrical glass bottles.

The isolated strains were tested for antibiotic production in surface culture by removing 'plugs' from well-grown cultures on potato-dextrose agar and determining the inhibition zones produced when the agar 'plugs' were placed on microbiological assay plates seeded with homogenized mycelium of *V. inaequalis*. Strains producing inhibition zones were afterwards tested for antibiotic production in submerged culture on three different fermentation media by 'cup-plate' assay of the fermentation broth against *V. inaequalis*, on the 2nd, 3rd and 4th days after inoculation. Antibiotics giving zones of inhibition greater than 20 mm. diameter were again produced by fermentation, but this time on what had been found the best of the three submerged fermentation media; the antibiotic production was assayed by incorporating serial dilutions of homogenized broth into agar slopes and then inoculating the surface with an homogenized culture of *V. inaequalis*. Antibiotics that completely inhibited growth of *V. inaequalis* at broth dilutions in the range 1 in 80 to 1 in 1,280 were considered to be worth extraction.

The technique was to submit broths from completed fermentations to a number of different extraction procedures, with 'cup-plate' assay of extracts and spent broths. Similarly, adsorption or non-adsorption on ion-exchange resins was determined by 'cup-plate' assay of the resin filtrates and eluates. The results enabled a suitable procedure to be devised for preparing a crude extract of the antibiotic.

Fermentations with the selected strains were repeated under optimum conditions in submerged culture, but now in two 5-litre mechanically agitated and aerated laboratory fermenters[1], the bulked broth at the end of the fermentation was extracted by the selected method to give approximately 25 ml. of a highly concentrated solution in acetone. These 'first concentrates' were scrutinized in several ways (extraction pattern, ultra-violet absorption spectrum, chromatography and bio-autographs, microbiological 'spectrum' *in vitro*, phytotoxicity and antifungal foliage protection tests) so as to eliminate unwanted antibiotics (polyenes, antimycin complex, oligomycin complex and cycloheximide). It became clear, after considerable experience of this procedure, that an apparently new antibiotic, designated venturicidin, was being produced by several strains of streptomyces and that it was both non-phytotoxic and highly active against a wide range of plant pathogenic fungi.

In general, it was observed that strains producing venturicidin gave 'first concentrates' which completely inhibited *V. inaequalis* in tube assay down to dilutions of 1 in 100,000. Similarly, the 'first concentrates' usually gave inhibition zones against *Cercospora melonis* in 'cup-plate' assay down to dilutions of the order of 1 in 100,000. This plant pathogenic fungus being more suitable than *V. inaequalis* for use in assays of this type, it was selected as convenient for microbiological assay of solutions of venturicidin in 50 per cent acetone.

'First concentrates' containing venturicidin were obtained from several strains and gave good protection in greenhouse tests against *V. inaequalis* when applied at dilutions of 1 in 500 to 1 in 2,000 to the foliage of pot-grown apple root stocks (Malling/Merton 106 and Malling XVI). Similarly, excellent protection was given to barley seedlings against *Erysiphe graminis*. In no test did venturicidin show any signs of phytotoxicity.

Further extraction tests on fermentation broths accompanied by appropriate 'cup-plate' assays led to an improved technique for extraction, this was applied to the preparation in two 5-litre laboratory fermenters of an improved 'second concentrate' and then for provision of crystalline venturicidin from 225-litre stainless steel pilot-plant fermenters

The method of preparing crystalline venturicidin is summarized here, together with its main chemical and biological properties

Crystalline Venturicidin

Strains Venturicidin is produced by three distinct strains of *Streptomyces* having a general resemblance to *Streptomyces griseolus* and *S halstedii* and some affinity with *S xanthophaeus* They have been found in soils from many parts of England and also from New Zealand Typical members of these three strains have been deposited in the National Collection of Industrial Bacteria under Culture Nos N C I B 9198, N C I B 9199 and N C I B 9200

Fermentation Vegetative inoculum was grown in a 5-litre laboratory fermenter containing 'Sabouraud' and malt medium (2 per cent 'Oxoid' malt extract, 4 per cent glucose, 1 per cent 'Oxoid' peptone) and transferred at the 28th hr to a 225-litre pilot-plant fermenter containing the medium (3 per cent Rickard's oat-flour, 1 per cent light precipitated chalk, 0 75 per cent glucose). The fermentation temperature was 28° C and the broth was extracted after three days

Extraction. The broth was filtered at *p*H 6 and the filtrate discarded The mycelium was extracted at room temperature with acetone and the extract was freed from acetone by concentration under reduced pressure with addition of a little water, as necessary. The aqueous solution was extracted at neutrality with light petroleum (60–80°) to remove antifoam oil, and any venturicidin that had been inadvertently extracted was afterwards recoverd by re-extraction with 90 per cent methanol The aqueous methanol solution was freed from methanol under reduced pressure, and the aqueous residue was combined with the main aqueous solution before extraction with ethyl acetate The ethyl acetate extracts were dried over sodium sulphate and taken to dryness under reduced pressure to give an oily solid.

Crystallization A typical crystallization was carried out by the following procedure To 2 48 gm of crude oily solid, 25 ml of carbon tetrachloride were added The oil dissolved, but precipitation of semi-crystalline material occurred immediately, it was removed by filtration and washed with carbon tetrachloride to give 610 mgm of almost colourless solid This was dissolved in 7 ml of hot methanol, and 2 ml of water were added On cooling, 590 mgm of needle-shaped crystals (m p 128–132° C) separated

Alumina chromatography The procedure used in a typical purification was as follows A column was prepared with 15 gm of 'Woelm' alumina (neutral grade 1) 579 mgm of crude oily solid were added in 5 ml of chloroform Continued elution with chloroform eliminated 145 mgm of oily material, after washing the column with ethyl acetate, 95 mgm of a biologically active fraction were eluted with ethyl acetate containing 5 per cent methanol. This material was crystallized from methanol/water to give a solid (m p 135 5–137 5° C) and further purified by alternate re-crystallizations from ethyl acetate/light petroleum and methanol/water, to give crystalline material [m p 140–142° C (uncorrected), $(\alpha)_D$ = + 110° (*c* 1 per cent, chloroform)], containing only one biologically active substance, as shown by bio-autographs of chromatograms developed in several solvent systems.

Chemical properties Venturicidin is a neutral substance It is soluble in butanol, ethyl acetate or chloroform It is stable at room temperature at *p*H 7 It gives negative ferric chloride, ammoniacal silver nitrate and anthrone tests, but shows a red coloration with 2,4-dinitrophenylhydrazine

Prof B Lythgoe, of the University of Leeds, is now investigating the structure of venturicidin, and we are grateful to him for the following results

m p. 142–143° C , $[\alpha]_D$ = + 114° (*c* 1 per cent, chloroform)
Found C $\begin{matrix}64\ 7, & 65\ 1\\ 64\ 65, & 65\ 1\end{matrix}$, H $\begin{matrix}9\ 0, & 9\ 0,\\ 8\ 95, & 8\ 85\end{matrix}$, N 1 75, 1 75, 1 75,
O (Unterzaucher) 23 95, 23 5
Calculated for $C_{43}H_{71}O_{12}N$ C 65 0, H 9 0, N 1 75, O 24 2 per cent

Venturicidin can be conveniently prepared as a 10 per cent water-miscible solution in 'ethyl cellosolve' with addition of a suitable surface-active agent, on dilution with water this provides solutions of venturicidin, at concentrations between 200 and 25 μgm /ml , suitable for application to plant foliage

Biological activity of venturicidin in vitro Crystalline venturicidin is antifungal but not antibacterial, though when crude it is sometimes associated with antibacterial material Minimum concentrations in 50 per cent acetone producing inhibition zones in 'cup-plate' assays are given in Table 1.

Table 1 MINIMUM CONCENTRATIONS OF VENTURICIDIN NEEDED TO GIVE INHIBITION ZONES IN 'CUP-PLATE' ASSAYS AGAINST PLANT PATHOGENIC FUNGI

Fungus	Minimum inhibitory concentration (μgm /ml)
Ascochyta pisi	40 0
Aspergillus niger	5 0
Alternaria tenuis	5 0
Botrytis cinerea	2 5
Cercospora melonis	1 25
Didymella lycopersici	2 5
Fusarium nivale	2 5
Glomerella cingulata	10 0
Helminthosporium avenae	2 5
Phoma betae	5 0
Pythium de Baryanum	5 0
Penicillium expansum	10 0
Thielaviopsis basicola	20 0
Trichothecium roseum	5 0
Ustilago maydis	5 0
Verticillium albo-atrum	2 5

Tube-dilution assay (antibiotic incorporated in agar and test fungus inoculated to the surface) gave the results as follows

Venturia inaequalis complete inhibition at 1 μgm /ml and partial inhibition to 0 1 μgm /ml
Sclerotinia fructigena complete inhibition at 0 3 μgm /ml. and partial inhibition to 0 01 μgm /ml
Botrytis cinerea complete inhibition at 0 3 μgm /ml
Glomerella cingulata, *Cercospora melonis*, *Fusarium nivale* } partial inhibition to 0 3 μgm /ml

Venturicidin also exhibited exceptionally high activity against *Nocardia rubra* (complete inhibition by 0 08 μgm /ml after 7 days in liquid tube dilution assay) and markedly inhibited *Aspergillus fumigatus* and *Blastomyces dermatitidis* at concentrations between 20 and 1 25 μgm /ml

Greenhouse protection tests with venturicidin against plant pathogenic fungi Crystalline venturicidin gave excellent protection against a number of plant pathogenic fungi when used as a prophylactic foliage spray in greenhouse tests For example, at LD_{90-95}, 20 μgm /ml venturicidin was approximately as effective as 200 μgm /ml Captan against apple scab *V inaequalis*) and was about as good as 200 μgm /ml

Karathane against barley mildew (*E graminis*) Venturicidin is also exceptionally active against broad bean rust (Hunnam, D , and Smith, C B F , private communication) and has some activity at concentrations of 20–40 µgm /ml against cucumber mildew (*Erysiphe cichoracearum*), apple mildew (*Podosphaera leucotricha*) and grey mould (*B cinerea*) on tomatoes and vines Venturicidin showed local systemic action in apple foliage and some eradicant action against *V inaequalis*

Pharmacology of venturicidin Preliminary results on mice and dogs show venturicidin to be non-toxic orally, besides having low intraperitoneal toxicity and relatively low intravenous toxicity (Tomich, E G , private communication)

It is concluded that venturicidin is a new antibiotic with considerable potential use in agriculture It is now undergoing commercial evaluation as a fungicide against apple scab (*V inaequalis*)

We thank our colleagues, Mr W K Anslow and Mr D Fletcher, who were responsible for the 5-litre and pilot-plant fermentations

STRUCTURE OF THE PLANT STEM IN RELATION TO ADVENTITIOUS ROOTING

By A. BERYL BEAKBANE

East Malling Research Station, Kent

THE ability of one-year-old stems to form adventitious roots has been found, in a range of fruit plants, to be closely related to the anatomical structure of the primary phloem of the stem Shoots of shy-rooting varieties are frequently characterized, in this tissue, by a high degree of sclerification, that is, differentiation into fibres and sclereids In Conference pear, for example, an almost continuous cylinder of mature thick-walled fibres without living protoplasts encircles the secondary phloem and appears, in transverse section, as a ring of lignified tissue (Fig 1) In ready-rooting plants it is usual to find that most of the primary phloem parenchyma cells retain living protoplasts even when they are in a stage of transition to sclerotic parenchyma, or sclereids It follows, therefore, that in stems possessing a high rooting propensity many of the phloem rays abut, at their distal ends, on areas of living tissue (Fig 2) in contrast to the shy-rooters, where the phloem rays are frequently blocked by heavily lignified elements (Fig 1) The degree of continuity of the sclerenchymatous ring is compared, in Table 1, with ease of propagation as shown by the behaviour of stooled plants reported by Garner[1] As the propagation capacity falls, the continuity of the ring increases

A similar general relationship between the degree of sclerification of the primary phloem and rooting ability has been observed among rootstocks for stone fruits, and in a range of flowering shrubs from temperate regions Shoots of certain shy-rooting tropical plants, including *Hevea brasiliensis* sent from Malaya and *Acacia mearnsii* sent from Natal, have been found to possess, at the base of one-year-old stems, an almost unbroken cylinder of mature lignified elements, similar in continuity to that of the shy-rooting Conference pear, but differing in composition as regards type of element Working with stem cuttings of the olive in Italy, Ciampi and Gellini[2] noted a similar connexion between the absence of a sclerenchymatous ring and rooting potential Thus a relationship between structure and rooting capacity would appear to be applicable to a wide range of species That the presence of periphloic sclerenchyma is not the sole cause of the prevention of easy rooting is, however, shown by the following examples species of *Pittosporum* lacking such sclerenchyma are, nevertheless, difficult to root, as are also certain *Erica* spp where a phellogen is laid down on the inner side of the periphloic sclerenchyma (C R Metcalfe, private communication)

Inherent differences between clones in the degree of sclerification of the primary phloem have been found to be relatively stable in material grown under comparable conditions at East Malling Environmental effects may, however, be superimposed on the inherent structure, differentiation of the primary phloem parenchyma cells into fibres and sclereids being retarded, for example, by shading, and by partial etiolation as in the earthing up of stool shoots, or marcotting of aerial stems

Comparisons between shoots exhibiting juvenile characteristics and mature shoots, both derived from the same plant, have indicated that, in seedling apples, the basal juvenile shoots are relatively free from sclerotic cells in the primary phloem compared with lateral shoots from fruiting branches close to the apex of the maturing tree These observations provide indirect evidence of a relationship between

anatomy and rooting potential since loss of rooting ability over the period of change from juvenility to maturity, first reported in 1929 by Gardner[3], is now well established for a number of plants, including the apple Ready-rooting sphaeroblast shoots, artificially induced by continuous removal of normal bud meristems[4], have also been found to have fewer fibres and sclereids in the primary phloem than shy-rooting normal shoots from the same apple clone

Sphaeroblasts are small woody inclusions occasionally found in the bark of many tree species These nodules, which are separated from the central vascular cylinder, possess a cambium and may continue to grow over a period of years, forming annual rings and eventually protruding conspicuously from the trunk Following certain stimuli, including severe pruning accompanied by the removal of all lateral buds and of any subsequent shoots from dormant buds, young sphaeroblasts may grow out producing either rosettes of leaves or long shoots The work of Baldini and Mosse[7] on the inception of sphaeroblast primordia in apple has shown that sphaeroblast shoots arise adventitiously from a massed meristem originating in a primary tissue, thus providing anatomical evidence of juvenility, supporting the observations of Stoutemyer[5] and Wellensiek[6] that adventitious shoots from sphaeroblasts exhibit juvenile morphological characters If sphaeroblast shoots are in a more juvenile phase than those arising normally from a cambial meristem, the differences in anatomy between them provide a further example of the increasing sclerification of the primary phloem with advancing maturity of the tissue and they are in line with the suggestion made by Foster[8] that sclerification is an aspect of tissue senescence

It is obvious that if a correlation exists between the degree of sclerification of the primary phloem and rooting capacity, the rooting of difficult subjects might be facilitated by using very young shoots taken before the cells of the primary phloem lose their living protoplasts This method is, of course, exploited in propagation of softwood cuttings under mist where rapidly growing shoots are used At this stage of development, wall thickening may have begun in primary phloem cells destined to become fibres, or sclereids, but lignification is usually absent, or slight, and the cells retain a living protoplast in all except the most shy-rooting kinds In plants that are exceptionally difficult to root, even from softwood cuttings as, for example, beech, the onset of tissue senescence in the phloem appears to be very rapid, and, in addition to the formation of a sclerenchymatous cylinder in the primary phloem, the broad multiseriate secondary phloem rays may become lignified in quite young tissue close to the cambium (Fig 3)

The simplest explanation of the effect of a sheath of lignified tissue on rooting capacity would be a mechanical one, but this is probably not the sole—or even the major—cause of failure to root since, in many plants, root initials do not form at all readily within such a sheath Some alternative hypotheses are at present being investigated

Quite apart, however, from speculations on the mechanisms involved, it would appear that the observed relationship between anatomy and ease of rooting may have a practical application and that, within certain limits, it may be possible to forecast rooting capacity from the structure of young stems

Thanks are due to Dr C R Metcalfe, keeper of the Jodrell Laboratory, Royal Botanic Gardens, Kew, for having suggested this investigation, and to Mr R J Garner for providing much of the material and giving information on the rooting of a number of clones

GEOPHYSICS

A Morning Discontinuity in the Orientation of Quiet Auroral Arcs

From all-sky camera recordings taken at this Observatory (geographic co-ordinates 67·8° N., 20·4° E., geomagnetic co-ordinates 65·3° N., 115·5° E.) during the period December 1958 – March 1961 the directions of 366 quiet auroral arcs were measured. Only arcs extending from horizon to horizon, or at least covering an angle of view of about 100° for the most distant arcs and having an elevation angle of more than 15° for the highest point, were used in the analysis.

With the assumption of a constant height along the lower limit of the luminosity—for which there is good evidence (cf. Störmer[1])—the angle between a straight line connecting the points at which the arc intersects the horizon and a line through the midpoint of the chord, parallel to the meridian through Kiruna, was measured. Although this angle may differ slightly from that between the projection of the arc on Earth's surface and the local meridian through the midpoint of the arc—as measured by most investigators before the advent of all-sky cameras—the difference is estimated at less than one degree in the actual case. Since this difference is less than, or at the most equal to, the error introduced in measuring the angle of the chord, it has no appreciable influence on the results obtained. To the types of uncertainties mentioned should be added the possible error introduced in extrapolating some of the arcs to the horizon. Since this is estimated at 1–3°, the total error in the obtained direction of an arc will certainly not exceed 4°.

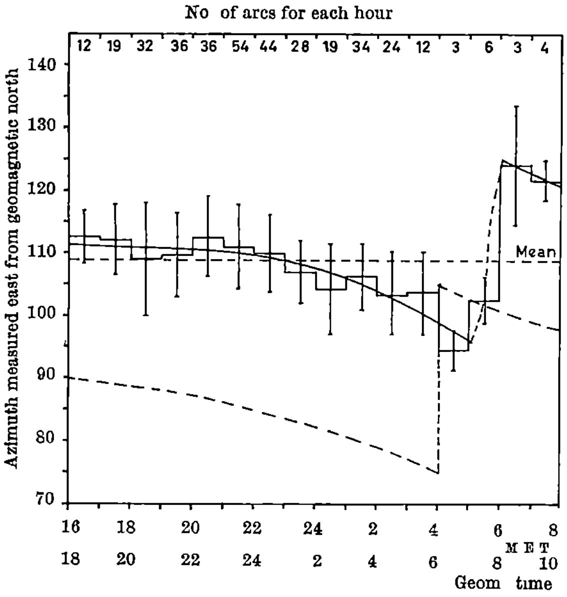

Fig. 1. Observed directions of quiet auroral arcs at Kiruna as a function of M.E.T. and of approximate geomagnetic time. The average azimuth and the standard deviation are given for each hour. The lower, dashed curve is Alfvén's theoretical diurnal variation curve

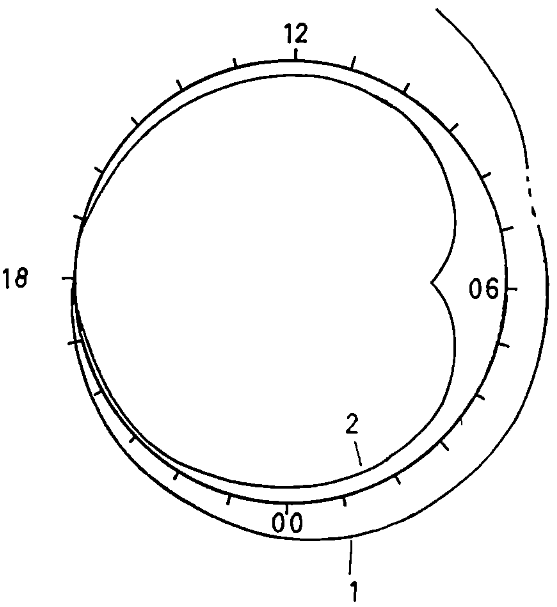

Fig. 2. Curve 1 is the auroral curve on Earth corresponding to Alfvén's I-curve, plotted from the diurnal variation in the orientation of quiet auroral arcs observed at Kiruna. It is corrected for the non-dipole part of the geomagnetic field. Curve 2 is Alfvén's theoretical I-curve

The result of the alignment investigation is shown in Fig. 1. For each hour of M.E.T. the average direction and the standard deviation were computed. In so doing, the direction value of each arc was weighted with the duration of the arc. The total average for the whole material was 109° and a typical standard deviation was 6°.

At the top of Fig. 1 the number is given of arcs used for each hour. The number has a maximum around geomagnetic midnight. In the morning hours the aurora as a rule is not suitable for direction determination, being usually diffuse and situated far to the north. It is not surprising, therefore, that the observational results are least for those hours. The morning arcs for which the direction was measurable were all of short duration.

Although the observational material is not extensive for the interval 0400–0800 M.E.T., it allows the conclusion that the very rapid increase of the azimuth occurring between 0500 and 0600 M.E.T. is significant.

The azimuth change in the morning is so rapid as to resemble a discontinuity of the type predicted by the Alfvén theory[2]. Such a marked 'discontinuity' has not, to our knowledge, been observed before. Lassen[3] observed a rapid change in direction at Godhavn at approximately the same local time, but the amplitude of the change was less (about 20° as compared with 30° in Kiruna).

In point of fact it should be possible to observe the discontinuity only in those longitudes in which geomagnetic time runs ahead of local time, since daylight will preclude auroral observation until 8 or 10 o'clock (geomagnetic time) in other longitudes.

From the smoothed diurnal variation curve of Fig. 1 the auroral occurrence curve—corrected for effects of the non-dipole part of the geomagnetic field—corresponding to the 'ideal auroral curve' (the I-curve) of Alfvén[2] was plotted and is shown in Fig. 2 together with Alfvén's theoretical I-curve. The entire experimental curve is situated outside the circle, with which it coincides at 1800, in contrast to the theoretical curve, which is inside the circle. The difference is attributable to the fact that the azimuth values of the experimental curve are 7–9° greater than the values of the theoretical curve even after correction for the effects of the non-dipole components of the geomagnetic field. Hence, the theoretical curve is situated outside the standard deviation 'region' of the observational material. The difference, therefore, is probably a real one, which is not surprising since the theoretical curve is based on a highly idealized model.

ASTROPHYSICS

Lunar Dust and the Gegenschein

OF the four possible explanations of the gegenschein which have been proposed, not one so far has explained satisfactorily the meagre observational data concerning this phenomenon. The Glyden–Moulton hypothesis[1], which suggests a concentration of meteoric material at a libration point of the Sun–Earth system, seems incapable of explaining all the luminosity of the gegenschein. The zodiacal light hypothesis[2], which claims that the glow opposite the Sun results from a phase-function for the interplanetary dust layer which produces such a brightening, fails to explain the fact that the gegenschein usually lies approximately 3° west of the anti-solar point[3]. The gaseous tail hypothesis[4,5], in explaining the light as the result of excitation of Earth-escaped gases by the interplanetary plasma, does not account for the fact that the colour of the gegenschein is slightly redder than that of the Sun[6]. Finally, the dust tail hypothesis[7], although explaining the facts in a qualitative way, at least, requires a large and continuous source of dust particles in Earth's neighbourhood.

Before the satellite measures of interplanetary dust concentration became available, there was little reason to suggest such a source of dust in the immediate vicinity of Earth. However, the remarkable fact that Earth is surrounded by a concentrated dust layer[8] seems to be explained in no other way. Whipple has found that the Moon might be the source of Earth's dust layer, for under certain conditions, the velocities of fragments thrown up from the lunar surface as a result of meteorite impact will exceed the lunar escape velocity. Many of these particles will be captured in quasi-stable orbits about Earth, forming just the sort of layer of dust found by the satellite experiments. Smaller particles will be blown out by radiation pressure before they can orbit Earth.

It seems reasonable to suggest that this localized source of dust in the immediate vicinity of Earth is sufficient to maintain a dust tail for Earth acted on probably by radiation pressure analogously with type II comet tails. If such is the case, then Earth has a dust tail as well as a gas tail[9], and we would be in the position of looking down the axis of the tail. To test such a hypothesis it will be necessary to work out theoretically the mechanism of supply of the dust layer and of its depletion. It will also be helpful to have further observations of the gegenschein to confirm its colour, spectrum, location, surface brightness, and variations in these quantities. Especially interesting would be systematic studies of the motions of the gegenschein and any relations these might have with other events. Measures of the parallax of the gegenschein should be attempted from an orbiting vehicle.

PHYSICS

Mode Characteristics and Coherence in Optical Ruby Masers

AN optical maser, using a good-quality ruby crystal with plane-parallel reflectors, oscillates in modes corresponding to Fabry–Perot resonances. Oscillations are shown to occur at several different wave-lengths corresponding to various numbers of half-wave-lengths between reflecting ends. For each wave-length, there are many angular modes which are coupled so that they oscillate coherently. This implies that a set of angular modes may be considered a single modified mode and that light from the entire set may be focused to a point of minimum size allowed by the wave-length of the light.

There have already been various discussions of the modes in an optical cavity[1–4] and experimental demonstration of a ring structure[5] in light emitted by ruby masers. The photograph shown in Fig. 1 was taken by passing a pulse from a ruby maser through a 410-mm lens, with the photographic plate in the focal plane (far-field pattern). The series of rings observed corresponds within the accuracy of measurement with the pattern of a Fabry–Perot interferometer. Separations between successive sets of rings follow the interferometer equation

$$D_n^2 - D_{n-1}^2 = \frac{4f^2\lambda\mu}{L}$$

where D_n is the diameter of the n^{th} ring on the film, f the focal length of the lens, λ the wave-length, μ the refractive index, and L the geometrical length of the ruby. The value of L obtained from this expression, on substitution of other quantities and measured values of D_n, agrees with the measured length of the crystal to within a few per cent. This was found to be the case for crystal samples of differing lengths, a fact which rules out interpretations of the rings on the basis of diffraction by some unidentified aperture

The ring pattern of Fig. 1 was allowed to fall on two 100μ apertures separated by 2 mm which accepted light from different rings or different portions of the same ring, corresponding to different angular directions of propagation within the ruby interferometer. Interference patterns characteristic of coherent sources resulted (Fig. 2), which reproduce the pattern found at a distance of 2·5 ft with no lens interposed. This implies that various angular modes are of precisely the same frequency and coherent in phase. They must therefore be effectively coupled. Scattering from lattice imperfections is known to be prominent, and can be expected to couple the various modes as a result of transfer of light between them.

One must not, however, assume that only one frequency is present in the oscillation. The photograph in Fig. 3 was taken by interposing between the ruby and camera an external Fabry–Perot interferometer of about 1-cm spacing. The ring structure of Fig. 1 is seen in the background of the various orders of the interferometer. The 'fine structure' components shown were measured and the wave-number difference of adjacent components was about 0·07 cm^{-1} which, for our crystal, is equal within about 10 per cent to the separation of longitudinal modes $\Delta\nu = 1/2\mu L$. Such separations have previously been measured directly as beats in the helium–neon and ruby systems[6,7].

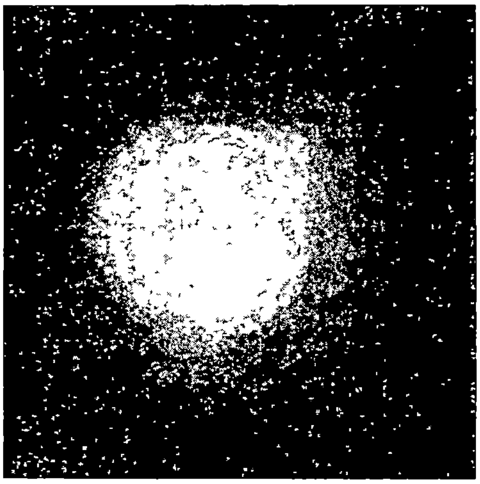

Fig. 1. Ring pattern formed by light beam from ruby maser at the focal plane of a lens. Spacing of rings corresponds to angular modes in ruby rod for a fixed frequency

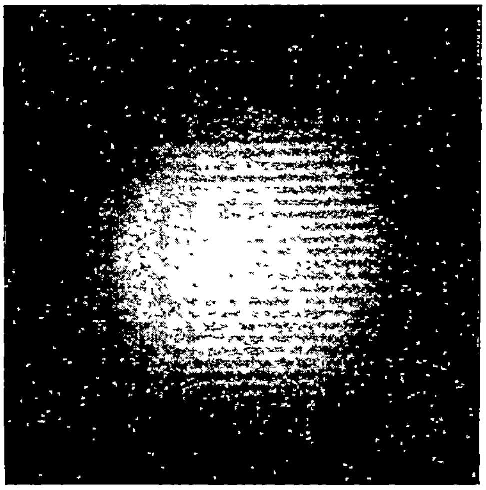

Fig. 2. Interference pattern produced by light from two small apertures transmitting beams from different parts of the ring pattern of Fig. 1

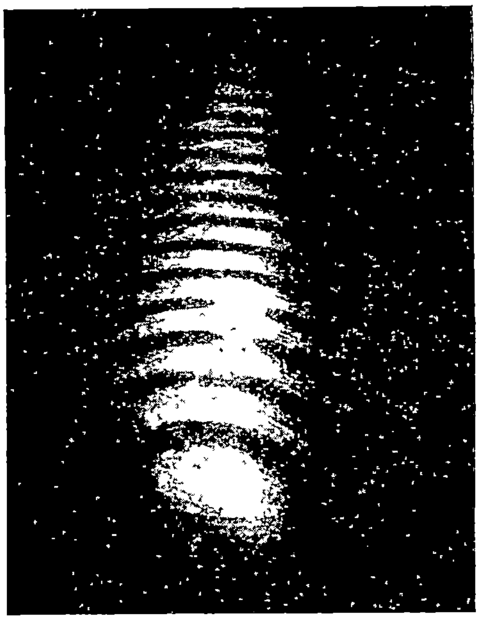

Fig. 3. Rings produced by beam from ruby maser after passage through a Fabry–Perot interferometer, showing resolution of longitudinal modes. The less obvious superimposed series of rings is the same shown in Fig. 1, which occurs without passage through a Fabry–Perot interferometer

The several frequencies shown in the pattern of Fig. 3 are, of course, all within the ruby emission line, and are so close together that their interference patterns can coincide in Fig. 2. Hence the emission of the ruby maser is composed of several different frequencies with separations determined by those of the longitudinal modes. Each of these frequencies is emitted coherently in a series of coupled angular modes. The large number of angular modes spreads the emitted energy into a beam the width of which in solid angle exceeds that of the diffraction pattern of the principal mode by as much as several orders of magnitude[8]. We mean by a principal mode one in which the wave propagation is essentially perpendicular to the reflecting ends, and hence which can be expected to have the lowest losses[1-4]. It should be noted that oscillations under many different conditions always showed a maximum in the direction of the principal modes. Presumably, it is the lower losses of these modes, and their saturation of adjacent frequency regions in the ruby emission during oscillation, which produce just those frequencies that correspond closely to several adjacent principal modes in the cases examined. One must expect under some conditions to find other combinations of frequencies.

It is interesting to note that the coherence observed between the angular modes, and the coupling which must exist between them, implies that the set of angular modes may be regarded as a single modified mode, in which the maser is oscillating. This means, further, that it should be possible to concentrate the energy at a point or in a beam as small as that allowed by coherent oscillations in any other form of single mode. Such a possibility can be of importance in concentrating large amounts of power from solid-state masers into small spots or highly directed beams For example, one may note that the successive rings in the focal plane of the lens may be all made to arrive in phase at any arbitrary point on the axis by interposing a suitable phase-shifting plate at each ring The light would then be focused as by a zone plate, and a suitable following lens could produce a beam of width limited primarily by the aperture of the lens

The phase coherence of the various angular modes implies also the existence of rings in the near field due to interference of the beams from these modes, which may be considered as a set of coherent waves travelling at various angles with respect to the axis Some rings have been observed in the near field by us and by others (Collins, R J , private communication), but they have not been carefully compared with expected theoretical behaviour

de Haas–van Alphen Effect in InBi

THE de Haas–van Alphen effect (oscillatory dependence of magnetic susceptibility on magnetic field strength at low temperatures) has provided one of the most successful methods for studying the Fermi surfaces of pure metals at low temperatures Recently the utility of this technique has been extended to semiconducting compounds with the observation of the de Haas–van Alphen effect in degenerate *p*-type PbTe (ref 1) In this communication we report what we believe to be the first observation of de Haas–van Alphen oscillations in a metallic compound, InBi (ref 2)

The single crystal of InBi used in the present investigations was obtained by mixing stoichiometric quantities of indium and bismuth in a 'Pyrex' glass tube under vacuum The molten compound was then forced under helium pressure into a tapered 'Pyrex' glass capillary which was allowed to cool slowly in a temperature gradient A cylindrical sample of length 13 mm and diameter 0 9 mm was cut from the capillary with a sandblaster, and the glass casing was dissolved with hydrofluoric acid An X-ray analysis showed the direction of the sample axis to be 33° ± 2° from a $<100>$ axis in the basal plane of the tetragonal crystal The pulsed field apparatus used in this work has been described briefly in previous communications[3,4]

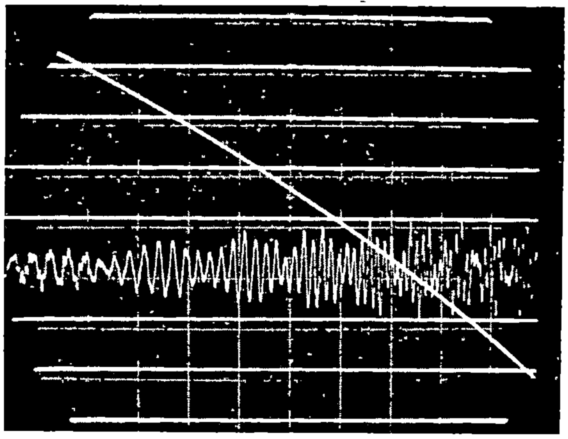

Fig 1 de Haas–van Alphen effect in InBi at 1 11° K The oscillating trace shows the output from a pick-up coil containing the sample The curved trace shows the magnetic field increasing from 80 1 to 130 6 k gauss during a sweep time of 1 8 msec (time increasing from right to left) The beating effect is due to two oscillating terms of different period and amplitude

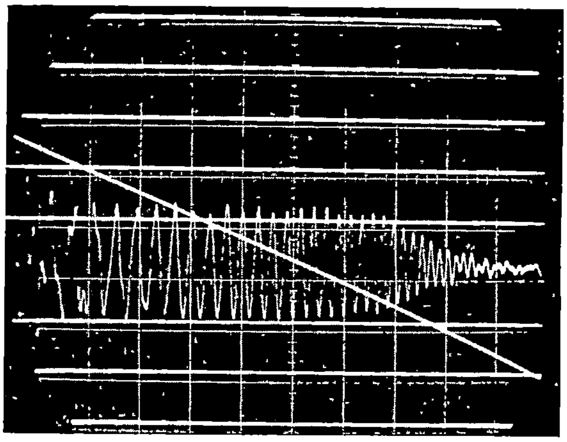

Fig 2 Long period de Haas–van Alphen oscillations in InBi at 1 11° K The diagonal trace shows the field increasing from 36 2 to 70 0 k gauss during a time of sweep of 0 9 msec The change in interval occupied by each successive oscillation is a consequence of the decrease of the time derivative of the magnetic field and the periodicity of the oscillations in H^{-1}

With the sample mounted with its axis parallel to the magnetic field (within ± 2°) we observed three oscillating susceptibility terms which are pictured in Figs 1 and 2 The pertinent de Haas–van Alphen parameters for these three periods are given in Table 1 The extremal cross-sectional areas, A, of the Fermi surface were calculated from the periods, P, by the relation $A = 4\pi^2 e/chP$ The effective mass for each period was determined from the temperature-dependence of the amplitude of the oscillations[5]

It is apparent that the ranges of de Haas–van Alphen parameters in InBi are similar to those characteristics

Table 1 PERIODS, CORRESPONDING FERMI SURFACE EXTREMAL CROSS-SECTIONAL AREAS, AND EFFECTIVE MASSES FOR DE HAAS–VAN ALPHEN OSCILLATIONS IN INBI (ACCURACY OF PERIODS IS APPROXIMATELY 5 PER CENT)

Period (10^{-8} gauss^{-1})	Area (10^{15} cm^{-2})	m^*/m_0
8 43	1 13	0 58 ± 0 1
6 33	1 51	0 64 ± 0 1
25 4	0 38	0 21 ± 0 05

of pure polyvalent metals[5]. The application to InBi of the nearly free electron model[6,7], which has met with some success in understanding pure metals, will be attempted when more data are available. de Haas–van Alphen measurements should be possible on a wide variety of metallic compounds, thus providing insight into the nature of electronic binding and structure in such materials.

A Method of Calibrating Two-Sphere Non-directional Radiometers

When two heated spheres, one black and one bright, but otherwise identical, are kept at the same temperature, they lose an equal amount of heat by conduction and convection[1]. Any difference in heat input is due to the difference in radiational exchange. Neither air temperature nor air velocity enters the calculations for determining the mean radiant temperature of the surroundings. The quantities needed are: the heat input of the two spheres; the temperatures of the two spheres (which should be equal); the surface area; the emissivities of the bright and the black sphere. Nickel[1] or gold[2] is used for plating the bright sphere.

Attempts have been made to predict the accuracy of the two-sphere radiometer from the above quantities. Roose[1] reasoned that, as the heat input can be measured with an accuracy of ± 0·5 per cent, the error in mean radiant temperature would be ± 0·36° F. Sutton and McNall[2] anticipated errors not exceeding ± 2° F.

The method now proposed avoids the need to measure surface areas and emissivities. Advantage is taken of times and circumstances when the readings of a globe thermometer[3] and of air temperature happen to be equal. This is so, for example, out of doors in the evening during the transition from solar heat gain to radiational loss; or it may be so indoors under certain conditions. In such circumstances, it is clear that there is then, for the time being, a state of thermal equilibrium in which globe temperature and air temperature are both equal also to the mean ambient radiant temperature, so that the latter is known. Thus, if the two-sphere radiometer is operated at such a time, the answer which it should give is known, and only the heat inputs to the spheres need be measured, in addition, in order to enable its calibration constant to be found.

Using the above method it was found that the average error when measuring mean radiant temperatures with the Sutton–McNall[2] instrument was 0·4 deg. F.; the highest deviation encountered was 1 deg. F.

BIOPHYSICS

Montmorillonite as a Caliper for the Size of Protein Molecules

It is known that proteins may be adsorbed from solution by the clay montmorillonite, leading to an increase in $d(001)$ crystallographic spacings[1]. In order to compare these increases with the size of protein molecules one must be certain that a complete mono-molecular layer of protein has been adsorbed, and this can be calculated to require 1·3–2·0 gm. of protein per gm. of clay. As the clay becomes saturated the adsorption isotherm levels off, but the isotherms are initially steeper than curves of the Langmuir type[2]. Assuming that protein molecules are spherical, we have calculated the expected $d(001)$ spacings and compared them with the experimental values found (Table 1). The agreement is moderately good for all but pepsin. Hæmoglobin appears to be adsorbed as a monomer, whereas lactoglobulin enters the clay particles as a dimer.

Table 1. Adsorption of Proteins by Montmorillonite

Protein	Mol. wt.	Adsorption (gm./gm.) Theoretical	Adsorption (gm./gm.) Experimental	Calculated mol. diam., Å	$d(001)$, Å Theoretical	$d(001)$, Å Experimental
Lysozyme						
(native)	14,700	1·3	1·3	32·6	42·2	44
(denatured)	14,700	—	1·3	—	—	46
Chymo-trypsinogen	22,500	1·5	1·4	37·2	46·8	40
Lacto-	35,000	1·7	1·5	43·8	53·4	54
globulin	(17,500)*			(34·8)	(44·4)	—
Pepsin	35,000	1·7	1·0	43·8	53	18
Hæmoglobin	63,000	2·0	1·9	53·2	62·8	53
(human)	(40,000)*			(45·6)	(55·2)	—

* These proteins dissociate under extreme conditions of dilution and/or salt concentration to give the values in parentheses (ref. 3).

Our result with native pepsin agrees with that of Talibudeen[4], namely, that the $d(001)$ spacing is about 18 Å for a wide range of amounts of protein adsorbed; it indicates an unfolding of pepsin molecules into extended polypeptide chains within the clay particles.

It has often been suggested that during heat denaturation of proteins there is a tendency for protein molecules to undergo unfolding or expansion. We have found that the $d(001)$ spacings of montmorillonite–lysozyme complexes are the same for adsorbed, heat-inactivated lysozyme as for native lysozyme, from which it may be concluded that lysozyme does not change drastically in shape on undergoing denaturation in solution.

Tobacco mosaic virus (isoelectric point 3·5) was allowed to react with sodium (Wyoming) bentonite at pH 3·2 (citrate buffer, ionic strength 0·0375). According to spectrophotometric analysis, 1,830 mgm. of virus was adsorbed per gm. of clay. At this value, about 15 per cent of the internal surface area of the clay could be covered with the virus However, X-ray data indicated that internal adsorption had not taken place

HYDROGRAPHY

Concentration of Chloride in Fresh Waters and Rain Water

A study of analyses of the waters of a number of freshwater lochs in the north-west of Scotland, sampled in 1955, showed that the chloride concentrations (Cl) varied with the distance (D) of the loch from the coast, the most suitable equation relating these parameters being of the form $Cl = K D^{-n}$, where K and n are constants This form of equation was used by Gorham[1] to describe similar data obtained from tarns in the English Lake District A second series of lochs in north-western Scotland, sampled in 1960, and an earlier series of samples from lochs on the island of Rhum, western Scotland, taken in 1958, have also provided data fitting the general equation adequately

For the Scottish lochs, which are situated near a very irregular coastline, the parameter D is estimated in a south-westerly direction (that of prevailing strong winds) to the coast exposed to open sea. Despite the necessarily imprecise measurement, it has been found that the coefficients of correlation r for the regression of chloride concentration on D, after logarithmic transformation, are close to unity Furthermore the various values obtained for the constant n are in close agreement The values of the proportionality constant K differ to some extent, but are nevertheless of a similar order The results are summarized in Table 1, in which other relevant information is included

The samples of loch water in each series were all taken within short periods of one month or less, in areas where chloride derived from terrestrial sources is insignificant All chloride is consequently derived from cyclic salts dissolved in rain water, or directly from sea-spray droplets The analyses of loch water can thus be considered as the integrated values of total precipitation (including sea-spray) draining from the catchment areas of the lochs, the period of accumulation being virtually the same for all lochs in any one group

In work of mine on the rainfall of the island of Rhum it has been shown that the sodium content of the total precipitation at one sampling station (Kinloch) was linearly related to the maximum gust velocity of the wind in the area during the appropriate sampling period, for velocities above a threshold of about 30 knots The chloride/sodium ratio varied little from that of sea-water It seems possible that the proportionality constant K depends at least partly on the wind velocity, the prevalence of high wind velocities in a particular area over a definite period of time giving high values of K

In addition to the four series of data from freshwater lochs, constants have also been calculated from two series of rainfall analyses taken from the references quoted and are included in Table 1 The values of n for these two series are similar to those calculated for the lochs They are derived from mean values of chloride concentrations in precipitation sampled regularly over long periods, and such mean values can be considered as analogous to the loch water analyses

The mean value of the constant n, for the six series of data in Table 1, weighted according to the number of samples, is 0 328, and the equation thus approximates closely to the form $Cl = K/\sqrt[3]{D}$ The correlation coefficient is high in all six series ($P < 0\ 001$), and the relationship appears to be valid for distances ranging from 0 1 to 80 km , and probably much longer It is suggested that the marine influence on fresh water is governed by such a relationship

Other attempts have been made to derive more complex relationships for data of the type discussed, variants of the general equation $Cl = ae^{-pD} + be^{-qD}$ being used (where a, b, p and q are constants) Eriksson[2] applied this equation to the data of Leeflang[3] while Conway[4] used a similar type of equation, with the addition of a further constant, to Jackson's[5] data The four constants in Eriksson's formula differ from the corresponding constants in Conway's formula An attempt to fit the Scottish data to an equation of the Eriksson type yielded constants differing from those of both Eriksson and Conway It is considered that the simpler formula $Cl = K D^{-n}$ has the merit of consistency in that similar values of n have been deduced from data obtained in widely differing regions, while the values of K are of a similar order, and are possibly related to the mean wind velocity in the area and sampling period concerned

No theoretical derivation of the proposed formula has been attempted, but it is probable that deviations can be expected at very short or very long distances. The deduced value of chloride concentration at zero distance would be infinitely large, perhaps represented by salt particles, although in practice this would not be found Topographical features no doubt also have some influence on the salt depositions While the proposed formula is doubtless a simplification of more complex equations which may govern the pheno-

Table 1

Location	No of sampling stations	Range of chloride concentration (Cl) m equiv /l	Range of distance (D) km	Sampling period	r	K	n	Reference

METALLURGY

A New Reversible Solid-State Transformation in Iron–Nickel Alloys in the Invar Range of Compositions

Unusual physical properties exhibited by alloys of the iron–nickel system in various ranges of composition have led to extensive investigations[1] of this system in the past One group of alloys is that contained in the invar range, namely, 30–45 atom per cent nickel, and is characterized by unusual thermal expansion, magnetic and other physical properties In spite of extensive investigations, the general sluggishness of solid-state transformations in the iron–nickel system has prevented true equilibria from being well established The properties of these alloys, therefore, have remained largely unrelated to their structural and/or crystallographic features

During a systematic re-examination of solid-state equilibria in the iron–nickel system, using new techniques capable of yielding true equilibria within reasonable lengths of time, we have found a new reversible transformation which occurs in these alloys in the temperature-range of ~ 150°–300° C In the present communication, this transformation is described and its possible bearing on the physical properties of the alloys discussed

Equilibrated iron–nickel alloys containing up to 75 atom per cent nickel were prepared in the form of pre-alloyed ultra-fine powders by the thermal decomposition and hydrogen-reduction of iron–nickel mixed-crystal formates[2,3] at various temperatures, including temperatures as low as 200° C Most of these alloys, as-quenched to room temperature from their respective temperatures of preparation, generally showed the equilibrium structures corresponding to the temperature of preparation However, alloys with 30–45 atom per cent nickel showed an exceptionally different behaviour which, on detailed investigation, proved to be due to the occurrence of the new transformation On re-heating, all the as-quenched alloys readily became transformed to yield equilibrium structures corresponding to the temperature of holding

As-quenched alloys were examined by X-ray diffraction at room temperature, using a Philips diffraction camera of 114 7 mm diameter High-temperature X-ray diffraction patterns were next obtained with a Unicam high-temperature diffraction camera which had been previously calibrated against the thermal expansion of gold Using a high-intensity rotating-anode X-ray generator, diffraction patterns could be secured with exposures as short as half an hour Cobalt and iron characteristic radiations were generally used, manganese radiation being used in those cases where high resolution was sought

Fig 1 Room-temperature X-ray diffraction pattern showing (311) back reflexion from a 31 atom per cent nickel iron–nickel alloy, alloy quenched to room temperature from the γ-state (~ 600° C) Manganese K_α radiation

Examination of the diffraction patterns revealed that the transformation occurs in all the face-centred cubic γ-phase alloys which contain approximately 30–45 atom per cent nickel When alloys of this structure and composition are quenched to room-temperature from the γ-phase, their X-ray diffraction lines always appear broad (Fig 1) That this broadening is not to be associated with quenching strains or with effects of fine particle-size became evident from high-temperature X-ray diffraction investigations during thermal cycling of the as-quenched alloys On heating to or above what appeared to be a critical temperature, the broad diffraction lines of the quenched alloys showed a pronounced sharpening Subsequent cooling resulted in loss of sharpness of the lines and the reappearance of their broadening (Fig 2) The effect has been reproduced repeatedly and takes place readily.

Closer examination of the broad lines indicated that the broadening may be interpreted as due to the superposition of two closely spaced reflexions having the same indices but arising from two face-centred cubic phases (designated as γ_1 and γ_2) of slightly different lattice constants The sharpening of the lines on heating may thus be attributed to the coalescence of the two γ-phases into a single γ-phase

In spite of the poor resolution of the X-ray diffraction lines, an attempt was made to measure the lattice parameters of the two γ-phases Typical results are shown in Table 1, from which it may be seen that the difference in the lattice constants is only about 0 008–0 009 Å

Transformation temperature appears to be dependent on the composition of the alloy Exact transformation temperatures for various compositions could not be determined, but they seem to lie in the

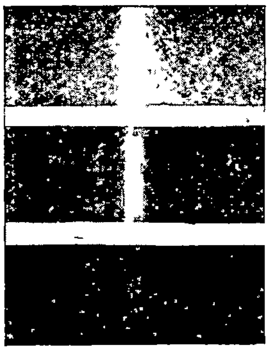

Fig 2 High-temperature X-ray diffraction patterns showing (311) back-reflexion from a 31 atom per cent nickel iron–nickel alloy, alloy as-quenched to room temperature from the γ-state subjected to thermal cycling Iron K_α radiation

Table 1 LATTICE CONSTANTS OF THE TWO γ-PHASES CO-EXISTING AT ROOM TEMPERATURE IN IRON–NICKEL ALLOYS WITH 31 AND 36 ATOM PER CENT NICKEL

Atom per cent nickel in alloy	Lattice constants (Å)	
	γ_1	γ_2
31	3 593	3 585
36	3 593	3 584

approximate range 150–300° C Note that the transformation occurs at relatively low temperatures Considering the general sluggishness of solid-state transformations in most iron–nickel alloys, rendered all the more sluggish at temperatures below 500° C , the reversibility of this transformation is indeed very striking

Observed features of the transformation are consistent with the interpretation that the transformation is of the magnetic kind, more specifically, ferromagnetic ⇄ anti-ferromagnetic Such a transformation may serve as the key to the proper understanding of the anomalies in thermal expansion, magnetic and other physical properties, for which the 30–45 atom per cent nickel iron–nickel alloys are noted The broad X-ray diffraction lines observed may thus be interpreted as due to the co-existence of ferromagnetic and antiferromagnetic modifications of the γ-phase in these alloys at these low temperatures Taking into account exchange interactions between iron–iron, nickel–nickel and iron–nickel atom pairs in iron–nickel alloys, the possible occurrence of such a transformation in precisely the same composition-range as of the alloys of this work has recently been considered by Kondorskii[4]

The validity of our interpretation of data, however, needs further confirmation through more refined experiments using methods other than X-ray diffraction, for example, magnetic analyses as well as neutron diffraction Work on these lines is now in progress

In attempting to correlate the changes of properties, for example, thermal expansion, saturation magnetization, etc , of these alloys with composition and structure, we are led to pose the question Should not magnetic transformations also be viewed as regular phase changes and therefore be given a fitting place in phase diagrams ? This question has far-reaching implications For example, if magnetic transformations are considered as regular phase changes, such concepts as 'solid phase' and 'crystal symmetry' will have to be modified to recognize the magnetic state of matter and the atomic symmetries associated with this state

Results discussed here together with unreported results covering compositions up to 75 atom per cent nickel, indicate that the iron–nickel equilibrium diagram is much more complex than the most recent diagram[5] drawn for this system We have constructed a new iron–nickel phase diagram which will be reported in the near future

CHEMISTRY

Relaxation Enhancement by Paramagnetic Ion Binding in Deoxyribonucleic Acid Solutions

THE effect of paramagnetic ions on proton relaxation times depends not only on their concentration but also on the binding of the ion to other molecules which may be present in the same solution By measuring longitudinal relaxation times (T_1) by nuclear magnetic resonance we have compared the proton relaxation-rates at constant ion concentration with and without deoxyribonucleic acid (DNA) present In this way it was possible to detect binding and to distinguish between interior and exterior DNA binding sites for different transition metal ions

In the present experiment T_1 was measured by the Carr–Purcell method[1] with a conventional spin-echo apparatus operating at 50 Mc /sec , for a wide range of magnetic ion concentrations in water and in calf-thymus DNA solutions

The Solomon[2]–Bloembergen[3] expression for T_1 in the presence of paramagnetic ions is

$$\frac{1}{NT_1} = \frac{4}{30}\,\frac{S(S+1)g^2\beta^2\gamma^2{}_I p}{r^6}\left[3\tau_c + \frac{7\tau_c}{1+\omega_s{}^2\tau_c{}^2}\right] + \frac{2}{3}\,\frac{S(S+1)A^2p}{\hbar^2}\left[\frac{\tau_e}{1+\omega_s{}^2\tau_e{}^2}\right]$$

in which N is the molar concentration of paramagnetic ions, γ_I the proton gyromagnetic ratio, p the probability that a proton is in the hydration sphere of the paramagnetic ion in a $1M$ solution of the ions, τ_c the correlation time for dipolar interaction, ω_s the angular electron precessional frequency, A the isotropic indirect hyperfine interaction, τ_e the correlation time for the isotropic hyperfine interaction (electron spin relaxation time, τ_s, or correlation time for proton chemical exchange in the hydration sphere, τ_h, whichever is shorter) and r is the ion-proton internuclear distance

At high fields, such as were used in the present experiments, the second term is negligible The correlation time τ_c is given by $1/\tau_c = 1/\tau_r + 1/\tau_h + 1/\tau_s$, where τ_r is the rotation correlation time

Consider how $1/NT_1$ is affected by paramagnetic ions originally in solution being bound to a molecule If the ion is bound to a single point (that is, not chelated) on the outside of the molecule, two degrees of rotational freedom are eliminated and the third may be reduced by the 'friction' of the hydration sphere against the molecule If the ion is chelated, rotation will in general be stopped completely In any event $\tau_r{}^*/\tau_r > 1$, where the asterisk denotes values for the bound ions If τ_s and τ_h are greater than τ_r and do not change appreciably when the ion is bound as is often the case, then $\tau_c{}^*/\tau_c > 1$ The number of water molecules in the hydration sphere of the bound ion is reduced slightly so that $p^*/p \approx 5/6$ In this case of large values of τ_s, therefore, the rate of proton relaxation in the presence of externally bound ions is greater than when the same concentration of ions is in solution If we define a relaxation enhancement factor $\varepsilon = T_1/T_1{}^*$ then $\varepsilon > 1$ This case is illustrated in Fig 1 for aqueous solutions of Mn^{++} ions and DNA

The second case is $\varepsilon < 1$, implying that p/r^6 and/or τ_c are reduced when the ion is bound, this has been used in several recent experiments[4]. The first alternative clearly indicates that the ion site is an interior one and not accessible to hydration water The latter can only arise from a large decrease in

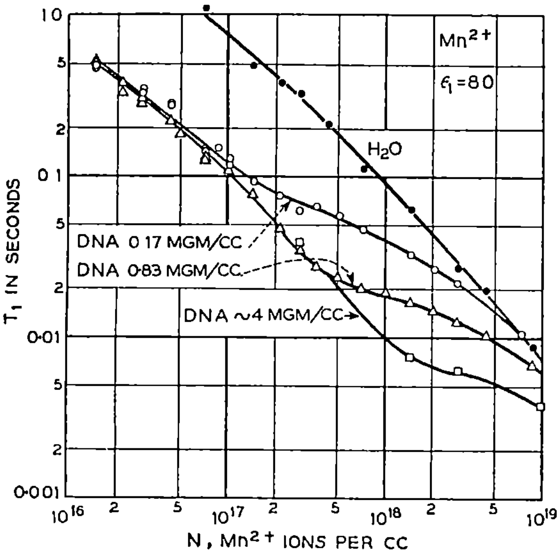

Fig 1 The curves show the proton T_1 as a function of Mn^{2+} ion concentration in pure water and DNA solutions of various concentrations The relaxation enhancement factor ε is approximately 8 0 for Mn^{2+} concentrations below the saturation value of 7 × 10^{17} Mn^{2+}/mgm DNA, which agrees with conductiometric measurements (ref 5)

electronic relaxation time on binding so that $\tau_s{}^*$ dominates $\tau_c{}^*$ (that is, $\tau_s{}^* < \tau_c$). In many cases even a rough knowledge of τ_s and $\tau_s{}^*$ makes the distinction between exterior and interior sites unambiguous

Our experimental results for aqueous DNA solutions may be summarized as follows

(1) For Cu^{2+}, Mn^{2+} and Cr^{3+} the measured values of ε are 10, 8 and 4 7, respectively We conclude that these three ions are bound to exterior DNA sites, probably to the phosphate groups

(2) For Fe^{3+} ε is 0 3 and if, as can be shown to be the case for the previously mentioned ions, $\tau_s \approx \tau_s{}^*$, we can conclude that Fe^{3+} is bound to an interior site

(3) Ni^{2+}, Fe^{2+} and Co^{2+} show $\varepsilon = 1$ Since these ions are known to have a very short τ_s, we can only conclude that they are either not bound to DNA or bound to an exterior site with $\tau_s{}' = \tau_s$ Recent experiments indicate that for Ni^{2+} and Co^{2+} the latter is the case[6,7] The number of available metal ion sites was found to be approximately 7 × 10^{17}/mgm of DNA for Mn^{2+}, Cr^{3+} and Fe^{3+} (~ 0 6 phosphate equivalent)

A detailed account of these experiments, which includes a discussion of the effect of the ionicity of the solution on the metal-DNA system, is being prepared

The experimental method described here should be generally applicable to other problems of paramagnetic ion bonding to large molecules An expression for $1/NT_2$ analogous to $1/NT_1$ leads to T_2 enhancement, which proves useful in the investigation of some ions

Detection by Ionization of Gases in Helium used in Gas Chromatography

THE recent communication of Karmen *et al*[1] on analysis by gas chromatography illustrates an interesting mode of operating a Lovelock ionization detector. The results given, however, do not indicate that the behaviour of the cell is in any way different from that used in the conventional manner The cell used by me[2] has a similar electrode configuration and the results, where comparable with Karmen's, are practically identical (see Table 1)

Table 1

	Concentration (volumes per million) for maximum conductivity		Relative responses for equal volumes		
	Karmen	Wiseman	Karmen	Wiseman (ref 2)	(*a*)
Hydrogen	—	~1,000	—	1	1
Nitrogen	520	750	4	3	~5
Argon	960	>170	3	5	5
Oxygen	280	250	11	10	10
Methane	—	⩾100	—	20	~10
Krypton	—	—	—	—	~18
Xenon	—	—	—	—	20
Carbon dioxide	80	170	5	70	—

(*a*) Previously unpublished results (Wiseman) using microargon detector

Some allowance must be made for the greater impurity of their helium, particularly in the case of carbon dioxide It is therefore not possible to accept their contention that the design of cell is more important than the purity of the helium

There are several points of considerable importance raised by their communication First, their implication that a cell specially designed for use with helium is likely to work better than one based on work with argon is almost certainly correct Secondly, to obtain the best results, a leak-tight detector is essential, but the short outlet illustrated in their diagram would appear to be inadequate to prevent back-diffusion once helium of really high purity was used. Thirdly, there are some serious implications overlooked in their acceptance of helium of commercial grade without further purification It is well known that bottles of commercial gases vary substantially in trace composition and in particular in water content Water appears to have an even higher response in these detectors than carbon dioxide Further, it is clear from Table 1 that were carbon dioxide the major constituent of the 100 v p m. impurity-level of the commercial helium, the helium would not give increases of conductivity with any gases Hence a mere specification of 99 99 per cent would be meaningless without some data on the nature of the impurities It is apparent from published data[1,2] that the tolerance of gases like argon and hydrogen is about 10 times that of carbon dioxide and probably water Karmen *et al* do not state whether they dry their helium. If they did, then possibly their specification is much better than indicated Even one molecular sieve trap in liquid nitrogen is a very effective purifier

Table 2

	Tolerable impurity-level (v p m)
Neon	10 (?)
Argon	10
Hydrogen	10
Nitrogen	5
Oxygen	3
Carbon dioxide	1
Water	<1
Hydrocarbons	1
Carbon monoxide	1
Total impurities	≯20

These figures are based on 1 per cent of the figure for maximum conductivity

Further disadvantages of using helium of relatively low purity are the reduction of the linear range—possibly even its complete elimination and the irregular calibration curve likely to result This could be S-shaped in character, and in any event as the conductivity/concentration curve reaches a maximum, the sensitivity of the device to changes of concentration reaches a minimum

In general, therefore, users should be recommended to obtain the purest helium possible compatible with reasonable trouble in purification A suggested specification for commercially available pure helium is given in Table 2

Quantitative Estimation of Peak Areas in Gas-Liquid Chromatography

Recently, Carroll[1] advocated the use of the product of retention time (t_R) and peak height (h) for the quantitative estimation of relative peak areas This method[2], based on the assumption of a proportionality of peak width (w) and retention time (t_R) or volume (V_R), gives satisfactory results with respect to the reproducibility. In fact, we have found that the reproducibility (under equal operating conditions) of this method is better than that of any other 'manual' estimation of peak areas However, the method is not commonly used in our Laboratory, as the results obtained with it are erratic This is due to the fact that in most cases the proportionality between w and V_R is only approximate Differences between the relative areas, as found by the triangulation method and from the product of h and V_R, can amount to several per cent relative In principle the non-linearity of w and V_R can be taken into account when calibrating the detector However, changing the column or altering the carrier gas velocity will change the calibration factors

Equation (17) in ref 3 can be written as

$$C_v = \frac{n^{1/2}}{V_R\sqrt{2\pi}} \exp\left(-n(V - V_R)^2/2V_R^2\right) a \qquad (1)$$

where n is the number of theoretical plates, V_R is the retention volume, V is the volume of carrier gas passed through the column since the introduction of the sample, C_v is the concentration of the component in the carrier gas, a is the amount of the component in the sample

From this equation it follows that (for a Gaussian peak)

$$h \times V_R \simeq \frac{n^{1/2}}{\sqrt{2\pi}} a \qquad (2)$$

Since n depends *inter alia* on the distribution coefficient[4], and thus on the retention time of the component, the relation between the product of h and V_R and the amount a will, in general, not be the same for every component. Therefore the method can only be expected to yield good results when the differences in retention volumes are very small, or when the C-term in the van Deemter equation is relatively unimportant, that is, when the linear gas velocity and the amount of stationary phase are small (influence of diffusion coefficients on n being neglected) In Carroll's measurements this is certainly not the case as the relative areas of the early peaks are larger when the triangulation method is used, whereas the relative areas of the late peaks are larger (with one exception) when the estimation is made from the product $h \times t_R$. Most likely in these experiments the distribution coefficient of the most volatile component (methyl palmitate) was larger than the ratio of the volumes of mobile and stationary phases in the column In consequence the number of theoretical plates must be expected to increase with the retention time This will explain the discrepancies between the results obtained by the different methods The same trend can be observed from the results summarized in Table 1

Table 1 AVERAGE RELATIVE AREAS OF SEVEN PEAKS IN A CHROMATOGRAM OF A HYDROCARBON MIXTURE

Distribution coefficient of component	Column length	2 m		2 m		4 m		4 m	
	Sample volume	2 5 µl		5 µl		2 5 µl		5 µl	
	Method	$h\,w$*	$h\,V_R$	$h\,w$*	$h\,V_R$	$h\,w$*	$h\,V_R$	$h\,w$*	$h\,V_R$
55		2 7	2 6	2 7	2 6	2 8	2 5	2 8	2 5
72		13 8	13 8	13 6	13 7	13 7	13 5	13 7	13 6
148		12 6	11 8	12 6	11 7	12 3	11 4	12 5	11 4
172		7 6	7 2	7 7	7 3	7 2	7 1	7 3	7 2

267		6 3	6 3	6 4	6 4	6 4	6 3	6 2	6 3
380		11 1	11 7	11 2	11 8	11 5	12 0	11 3	11 9

* w, width at half-height

Column, squalane on sterchamol (20 100), temperature, 50° C , ratio mobile to stationary phase, 6 (approximately)

The Perkin–Elmer *ABC* test mixture (hydrocarbons) was run on a 2-m and on a 4-m squalane column using 2 5 and 5 µl samples The relative areas of seven peaks of this mixture, given in Table 1, are the averages of the values obtained from five chromatograms

It appears that for accurate quantitative analysis the method advocated by Carroll is not suitable

[4] van Deemter, J J , Zuiderweg, F J , and Klinkenberg, A , *Chem Eng Sci* , **5**, 271 (1956)

In proposing the method referred to by Dijkstra, I tried to stress its convenience rather than its extreme accuracy and the examples which I gave were chosen to show that some lack of agreement might be expected in comparing areas determined by this method with areas determined by other methods However, as Dijkstra points out, results obtained with other methods are less reproducible Slight differences in the way in which triangles are drawn and small inaccuracies in cutting out curves can give rise to appreciable differences in estimated area It is also more difficult to measure peak widths at half height accurately than it is to measure retention times Furthermore, in the case of overlapping peaks it is frequently impossible to get a good estimate of the individual areas by other methods whereas the retention times and peak heights can still be measured and appropriate corrections for peak height applied if necessary

A convenient and rapid method with somewhat limited accuracy can still be useful in work where extreme accuracy is not required or where accuracy cannot be obtained in any event because of errors introduced by other steps in the analytical procedure However, it is always desirable to improve the accuracy of a convenient method, and this can sometimes be done when sources of inaccuracy are known For this reason I welcome Dijkstra's critical comment on the method for estimation of peak areas

Behaviour of 5*A* Molecular Sieve in Subtractive Gas Chromatography

5*A* molecular sieve can be used to remove selectively normal paraffins from hydrocarbon samples in the gas phase at the inlet of a gas liquid chromatographic column[1,2] This subtraction technique has formed the basis of analytical procedures for the determination of the normal paraffins in complex petroleum fractions and has been applied in conjunction with both packed and capillary columns[3]

It has also been shown that at high temperatures (*c* 300° C) normal paraffins could be removed in a similar manner from waxes but in this molecular weight-range only 2-methyl eicosane and the highly branched paraffin squalane were available to test the selectivity of the molecular sieve Neither of these compounds was sorbed by the sieve at a temperature of 320° C

Recently, Murray *et al* [4] have reported that unspecified single methyl branched paraffins in the wax range are completely removed from the gas phase by 5*A* sieve. This affinity for the singly branched paraffins was destroyed by repeated passage of these compounds through the sieve until no further sorption occurred However, the sieve was still capable of retaining the normal paraffins

We have now studied the behaviour of the single methyl branched hydrocarbons in greater detail using in particular a sample of 2-methyl dotriacontane synthesized in our laboratories[5] In these experiments a pre-column 6 cm long and 6 mm internal diameter was packed with activated 30–60 B S mesh 5*A* molecular sieve This pre-column was attached to the inlet of an 86-cm gas-liquid chromatography column, also of 6 mm diameter, containing 26 per cent wt of silicone grease *E* 301 on 52–60 B S mesh 'Sil-O-Cel' firebrick The pre-column was maintained at 320° C and the gas-liquid chromatography column at 296° C These conditions had been used previously for wax separations and were known to be satisfactory for such mixtures[3] 10-μl samples of pure paraffin hydrocarbons were introduced into the pre-column and their behaviour is shown in Table 1

At C_{33} the 2-methyl paraffin is completely sorbed whereas at C_{24} and below this type of compound is not sorbed by the sieve Also, when the branching occurs in the middle of the molecule the C_{44}-branched paraffin is retained, but the similar C_{26} compound is not sorbed At some critical chain-length between the limits indicated, single methyl branched paraffins start to be sorbed by the 5*A* sieve

Table 1 Behaviour of Paraffin Hydrocarbons in a Gas-Liquid Chromatography Pre-column containing 5*A* Molecular Sieve

Completely sorbed from the gas phase		Not sorbed from the gas phase	
Docosane	C_{22}	2-Methyl eicosane	C_{21}
Tetracosane	C_{24}	2-Methyl tricosane	C_{24}
Hexacosane	C_{26}	13-Methyl pentacosane	C_{26}
Octacosane	C_{28}		
Dotriacontane	C_{32}		
2-Methyl dotriacontane	C_{33}		
22-Methyl tritetracontane*	C_{44}		

* Gas-liquid chromatography column temperature, 350° C

Further work on the selectivity of the sieve will be carried out as more reference hydrocarbons in this range become available

We wish to thank Mrs M Colwell for the synthesis of some of the paraffins used in the work

Improved Gas Chromatography of Unesterified Fatty Acids

It has been demonstrated by Bottcher *et al* [1] and by Hunter *et al* [2] that unesterified fatty acids can be separated, by gas chromatography, by the use of 'liquid' phases of the polyester type Metcalfe[3] has pointed out the necessity to have a highly acidic 'liquid' phase in order to suppress the association of the carboxyl group of the fatty acids, and has shown that the separation of C_4–C_{22} fatty acids is very much improved by the incorporation of phosphoric acid in the polyester 'liquid' phase Using a column packing of 'Celite 545' previously coated with 25 per cent of diethylene glycol adipate polyester and 2 per cent of phosphoric acid, mixtures of fatty acids were separated at temperatures of 220–235° C , yielding well-defined symmetrical peaks and separating saturated and unsaturated acids from each other

The development of the argon ionization detector has resulted in higher sensitivities of detection allowing a reduction of sample size This reduction of sample size itself improves column efficiency and, in addition, allows the use of columns with lower content of 'liquid' phase, which in turn leads to improved resolution and a faster analysis A faster analysis is particularly important with the separation of fatty acids which are more thermo-labile than their corresponding methyl esters However, the choice of solid support is important when low ratios of 'liquid' phase to solid support are considered The use of a solid support having a large surface area per unit weight, such as 'Celite', is not particularly suitable in some respects, since treatment with the 'liquid' phase could leave much of the surface area uncoated, allowing the solid support to act as an absorbent and thus to interfere with the distribution of the analysis sample between the 'carrier' gas and the liquid phase

Bohemen and Purnell[4] have discussed the requirements of an efficient solid support These authors have shown that, as predicted by the van Deemter, Zuiderweg and Klinkenberg rate equation[5], high column efficiencies are attained when the columns have the following characteristics (*a*) narrow range of particle sizes, (*b*) spherical shape of particle, (*c*) small quantity of 'liquid' phase

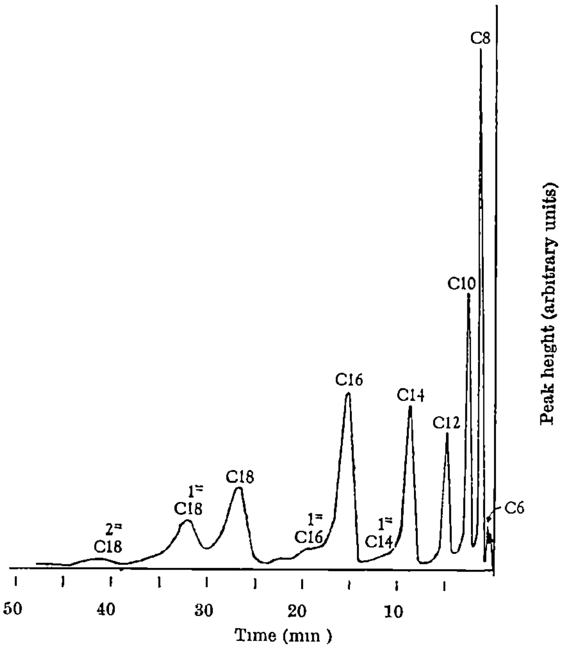

Fig 1 Chromatographic separation of a mixture of C_6—C_{18} fatty acids Sample size, 0 1 µl of a 50 per cent solution in cyclohexane Column temperature was 180° C , column size 1 2 m × 4 mm , argon pressure was 12 p s i at column inlet, atmospheric pressure at outlet

All these requirements can be fulfilled by using small glass beads of uniform size, which can retain up to 3 per cent of 'liquid' phase by surface tension

We have demonstrated that mixtures of unesterified C_6–C_{18} fatty acids can be analysed at temperatures ranging from 140° C to 200° C , by the use of a glass-bead support coated with a mixture of 1 per cent of poly-ethylene glycol succinate and 0 4 per cent of phosphoric acid

Poly-ethylene glycol succinate was prepared by heating a mixture of 1 0 mole of ethylene glycol and 1 05 moles of succinic acid at 150° C for 3 hr The resultant viscous liquid solidifies at room temperature and has a melting point of 80–82° C The polyester was used as 'liquid' phase without further treatment The polyester (0 5 gm) was dissolved in chloroform (30 ml) and to the solution was added, with constant stirring, 50 gm of glass beads (Ballotini, No 13 diam = 0 075 – 0 1 mm , manufactured by the English Glass Co , Ltd , Leicester), followed by 0 2 gm of phosphoric acid (85 per cent H_3PO_4) The stirring was continued while the chloroform was allowed to evaporate at room temperature When the packing was almost dry, it was finally rendered solvent-free by heating for 0 5 hr in an oven maintained at 100° C The coated beads were then sieved, and only the portion passing a 85–100 mesh sieve was used to pack the column The 1 2 m × 4 mm glass column was vibration-packed with the coated beads in the normal way The packed column was purged for 72 hr with a stream of argon, while the column was maintained at a temperature of 200° C For fatty acid analysis, the Pye gas chromatography apparatus was used, which utilizes argon as carrier gas and strontium-90 as the radioactive source for the ionization detector The mixtures of fatty acids analysed were dissolved in cyclohexane (50 50 w/v) and 0 1 µl of the solution was used for each experiment Normally, the detector voltage was 1,000 and the sensitivity control was set at × 10

Table 1 RETENTION TIMES (MIN) OF C_6—C_{18} SATURATED FATTY ACIDS AT VARIOUS COLUMN TEMPERATURES

Saturated fatty acids	Column temperature (° C) 140	150	160	170	180	190	200
C6	3 0	1 6	1 2	0 6	—	—	—
C8	6 4	4 0	2 8	1 6	1 4	1 0	—
C10	13 2	8 0	5 4	3 4	2 8	1 8	1 0
C12	27 0	16 0	10 6	6 6	5 0	3 0	2 0
C14	54 0	31 8	20 2	12 4	9 0	5 6	3 8
C16	107 0	62 0	37 2	22 4	15 2	9 8	6 2
C18	214 0	122 0	69 2	40 4	26 2	16 2	10 4

The separation of a mixture of C_6–C_{18} fatty acids, at 180° C , is shown in Fig 1 The approximate retention times of each of the component acids of this mixture, at various column temperatures, are given in Table 1 This illustrates that long-chain fatty acids can be separated rapidly at comparatively low temperatures

BIOCHEMISTRY

Oxidized Cytochrome and Chlorophyll C_2^+ in Photosynthesis

CHANCE *et al* [1a] reported the presence of trapped oxidized cytochrome in bacteria at –200° C , and in a previous communication[1b] we supplied evidence for the presence of trapped oxidized cytochrome during photosynthesis of green plants at –150° C We have now refined and extended the measurements over the whole range of the visible spectrum The difference spectrum of the trapped products in fresh spinach chloroplasts is shown in Fig 1*a* It shows in addition to the oxidized cytochrome Cyt$^+$ (solid line) the trapping of what is probably oxidized chlorophyll C^+ (dotted line) Both substances are products of one and the same light reaction $h\nu_1$ It has been shown that in green plants photosynthesis is triggered by two light reactions $h\nu_1$ and $h\nu_2$, one being sensitized by a chlorophyll pigment already sensitive at 710 mµ and the other sensitized by a chlorophyll pigment (*P*) sensitive at shorter wave-lengths (see refs 2 and 3) Exciting only $h\nu_1$ (at +20° C and 710 mµ) gives almost the same difference spectrum as presented in Fig 1*a* Two light-reactions in photosynthesis are discussed in the literature[2,5,6,8]

Information about the difference spectrum of C/C^+ in the range of 400–440 mµ (in Fig 1*a* masked by the absorption changes of cytochrome) and about the chemical nature of C/C^+ is given by experiments with aged chloroplasts of spinach Vernon, Kamen and Zaugg[4] have shown that aged inactive chloroplasts can again reduce triphosphopyridine nucleotide (TPN) in light after addition of reduced substances (dichlorophenol-indophenol with ascorbic acid) We observed that after such additions (reduced phenazine methosulphate, with ascorbic acid in excess) the aged

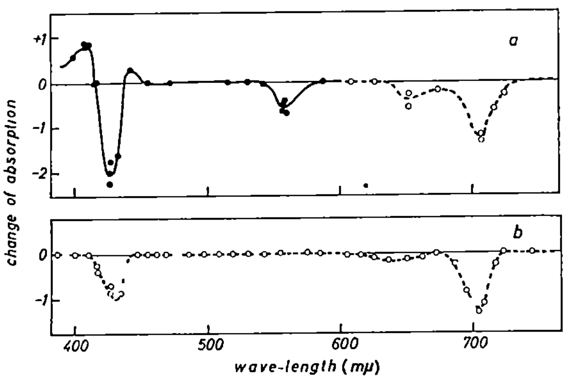

Fig 1 *a* Difference spectrum of the trapped products of photosynthesis in spinach chloroplasts at −150° C *b* Difference spectrum caused by illumination of aged chloroplasts with reduced phenazine methosulphate (PMS) at +20° C

chloroplasts showed a difference spectrum depicted in Fig 1*b* The changes of absorption at 430 and 703 mμ are both caused by one and the same substance *C* This follows from the identical behaviour of the changes at 430 and 703 mμ at different physical and chemical parameters For example. with increased concentration of reduced phenazine methosulphate (red PMS) the decay-time of the absorption changes at 430 and 703 mμ decreases from approximately 10^{-2} sec at 10^{-6} *M* to 10^{-4} sec at 10^{-4} *M* This means in addition that *C* is oxidized by light: $C \xrightarrow{h\nu_1} C^+$, and that C^+ is reduced by red PMS in a dark reaction $C^+ \xrightarrow[\text{PMS}]{\text{red}} C$ With the addition of reduced dichlorophenol-indophenol (red In) the decay-time at 430 and 703 mμ also decreases but only to a limited value of 10^{-2} to 10^{-3} sec depending on the condition of the chloroplasts This means that red In , contrary to red PMS, does not react directly with C^+ but via an intermediate reaction (with cytochrome, see later) with a duration of 10^{-2} to 10^{-3} sec By addition of different mixtures of ferro/ferricyanide it was possible to change the steady-state concentration of C/C^+ This can be seen by the dependency of the size of the light-induced absorption changes at 430 and 703 mμ on the ratio of ferro/ferricyanide From such measurements we have estimated the redox potential of C/C^+ as $+ 0{\cdot}45 \mp 0\ 01$ V at *p*H 6 and 8 Kok[5] has discovered and already reported in detail about the changes at 703 mμ and +20° C. He found that the unknown substance causing these changes has a redox potential of +0 46 V. and can be oxidized by light at 710 mμ and reduced by shorter wave-lengths Our measurements at 703 mμ and + 20° C confirm his results Our additional observation that in chloroplasts capable of reducing TPN the oxidation of *C* causes, apart from the changes at 703 mμ, a pronounced change at 430 mμ (see also ref 3) leads us to suggest that the difference spectrum shown in Fig 1*b* represents the oxidation of a chlorophyll-*a* Besides type 0 and type 1 (see ref 2) this is the third chlorophyll reaction observable in plants

By exciting *Chlorella* with 'flashing light' at +20° C it follows from the time of the changes of absorption (estimated at 703 mμ) that $C \longrightarrow C^+$ reacts within $< 10^{-5}$ sec The decay time of the changes, that is, the duration of the back reaction $C^+ \longrightarrow C$ in *Chlorella*, has been estimated at 430 mμ as approx 10^{-3} sec Contrary to the strong temperature-dependent life-time ($\tau \approx 10^{-2}$ sec) of the absorption changes at 475 and 515 mμ (see ref 2)—caused by an enzymic back-reaction (*E*) of a reduced substance $X^- \longrightarrow X$—the back-reaction of $C^+ \longrightarrow C$ is virtually independent of temperature (0–40° C)

Previous work[2] showed the time of cytochrome oxidation $\text{Cyt} \longrightarrow \text{Cyt}^+$ at 20° C and 420 mμ to be 10^{-5} sec This value is falsified by the absorption changes of $C \longrightarrow C^+$, which, as now can be seen, also take place at 420 mμ New measurements of the time of increase of $\text{Cyt} \longrightarrow \text{Cyt}^+$ at 405 mμ give a temperature-independent value of about 10^{-3} sec This value corresponds to the decay-time of $C^+ \longrightarrow C$.

The rapid increase of $C \longrightarrow C^+$ (less than 10^{-5} sec), the trapping of C^+ and Cyt^+ at −150° C , the production of C^+ and Cyt^+ in one and the same light reaction $h\nu_1$, the identification of *C* as chlorophyll-*a* and the fact that the decay-time of C^+ corresponds to the time of increase of Cyt^+ gave us the idea that the cycle of C/C^+ is the chlorophyll reaction operating between cycles 1 and 2 in Fig 2 of ref 2 This led to an extended reaction pattern shown in Fig 2 The trapping of both C^+ and Cyt^+ at −150° C is probably caused by a charge compensation at −150° C between C^+ and Cyt $C^+ + \text{Cyt} \rightleftarrows C + \text{Cyt}^+$ This is further evidence for the direct connexion of these substances

The energy difference between the cycles provides evidence that phosphorylation is generated by the energy released between cycles 3 and 4 (see ref 2) Losada *et al* [6] suggest phosphorylation between chlorophyll and cytochrome

As aged chloroplasts with red PMS show only changes of absorption at 430 mμ and 703 mμ (Fig 1*b*) it follows from Fig 2 that this system only operates with cycles 1 and 2 and is the most simple and stable photo-active unit in plants (C^+ reacts only with PMS in aged chloroplasts, in fresh chloroplasts C^+ is shielded from the attack of PMS) Addition of *p*-chlorophenyl-dimethylurea (CMU) or phenanthroline (strong poisons for oxygen production) have no influence on the absorption changes at 430 and 703 mμ in this simple system, this is in accordance with our scheme Aged chloroplasts with small amounts of red In show absorption changes at 430 and 703 mμ and the difference spectrum of cytochrome (Fig 1*a*) From Fig 2 it follows, therefore, that in this case cycles 1, 2, and 3 are operating (Cyt^+ is reduced by red In) In fresh chloroplasts with CMU or with phenanthroline, oxygen production is stopped, and

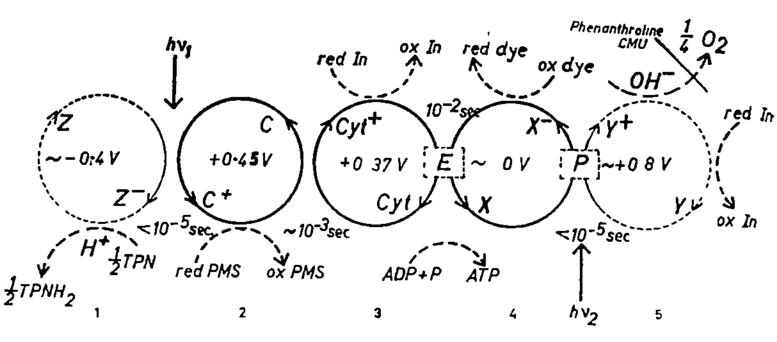

Fig 2 Reaction pattern of photosynthesis

no change of absorption can be observed By addition of red In , however, all changes of absorption, as well as those caused by X/X^-, reappear Therefore, in this case, cycles 1, 2, 3, 4 and 5 are operating and Y^+ must be reduced by red In instead of OH^- (Fig 2)

Losada *et al.*[6] have assumed that in fresh chloroplasts with CMU and red In one light reaction was separated by blocking the other one with CMU This cannot have been the case, since from the results reported here it follows that addition of CMU (blocking the production of oxygen by poisoning the reaction of Y^+ and OH^-) has together with red In no effect on either light reaction, because Y^+ can react with red.In instead of water (OH^-)

Note added in proof. Recently Kok[7] has reported changes in absorption at 432 mμ in inactive chloroplasts extracted with acetone He tends to ascribe these changes to those at 703 mμ and assumes tentatively that both changes are caused by a chlorophyll-*a*

New Ninhydrin-Reactive Substance from Red Algae

During an investigation on the free amino-acids in marine algae, I isolated a new ninhydrin-reactive substance from three species of red algae *Chondrus ocellatus*, *Neodelsea yendoana* and *Iridaea cornucopiae* by the use of anionic ion-exchange resin 'Amberlite *IR*–45' and 'Dowex 2'. This substance gave an empirical formula $C_5H_{11}O_5NS$ and melted at 258° C Optical rotation gave a value $[\alpha]_D^{13} = -1\ 15$ ($c = 5$, *M* sodium hydroxide solution) It was not very sensitive to ninhydrin, but gave a bright brown colour with Plattner's reagent. Titration with 0 1 *N* sodium hydroxide, in alcoholic solution, gave a value 63 80 per cent (calculated as C_4H_7N—SO_3H—COOH, 66 16 per cent) By the method of Kuhn and Roth, at least one radical, C—CH_3, was estimated The oxidation products obtained, after treatment with potassium permanganate solution, were taurine, alanine and propionic acid From these results, the structure *N*-(1-carboxy-ethyl)-taurine, that is  $(HO_3S{-}CH_2{-}CH_2{-}NH{-}\underset{\displaystyle CH_3}{\underset{|}{CH}}{-}COOH)$, was assumed Crystals obtained from α-brompropionic acid and taurine by chemical synthesis corresponded well with the isolated substance not only in melting point but also in R_F values on various paper chromatograms

Further investigations on the non-absorbable fraction of algal extracts on strong cationic ion-exchange resin revealed the wide distribution of this substance with taurine in red algae The only exception was in the case of *Chondria crassicaulis*, from which a sulphur-containing amino-acid, 1,4-thiazane-3-carboxylic acid *S*-oxide had previously been isolated[1] Not a trace of this substance could be detected here Furthermore, they have not been detected so far in brown or green algae

Sex Hormones as a Possible Factor controlling Biosynthesis of Arylesterase

Blood plasma arylesterase in pigs is controlled genetically by a set of alleles, each determining a plasma arylesterase activity of 0, 25, 50, 75 and 100[1] The distinguishable phenotypes are the manifestation of an additive effect of a pair of these alleles The plasma of new-born piglets has no arylesterase activity, and differentiation into groups of various esterase activities begins on the second to fourth day of life, adult values being reached at the age of about 50 days There are no sex differences for the biosynthesis of this enzyme, which, however, is influenced by sex hormones, as will be briefly reported here

In the genetical work, the male piglets were castrated at the age of three to four weeks. The adult arylesterase activity values of these boars were fairly constant However, certain male piglets were selected for use in later cross-tests With these uncastrated boars, it was observed that arylesterase activity after maturity was much lower than before sexual maturity[2]. For example, it was demonstrated that with a boar of esterase activity (phenotype) 150 before maturity, the activity gradually decreased with increasing age to a value of about 30, and that this low phenotypic activity was then fairly constant This phenomenon was found to be common to all mature boars, the low phenotypic esterase activity of which had no influence on expected segregation in the progeny. Evidence has now been presented that this decrease in arylesterase activity is due to the influence of male sex hormones on the biosynthesis of active protein. When a mature boar with a low phenotypic activity of 30 was castrated (Fig. 1*B*) the arylesterase activity increased gradually and had reached after 3 weeks a value (120–140) close to that found before maturity (150). Moreover, this high activity could again be reduced to the low value when 100–250 mgm of testosterone propionate was administered daily intramuscularly The low value was reached about three weeks after hormone treatment began Testosterone had no effect on the enzyme *in vitro*.

This observation has been confirmed with boars of various genotypes Testosterone also enhanced the decrease in arylesterase activity when administered shortly after maturity (Fig 1*A*) Female sex hormones (for example, œstradiol) had no effect on the biosynthesis of this esterase It is possible, however, that in addition to testosterone other agents (for example, the adrenocortical hormones) are also engaged in the regulation of plasma arylesterase activity in boars.

In contrast to mature boars, sows show small normal variations in plasma arylesterase activity

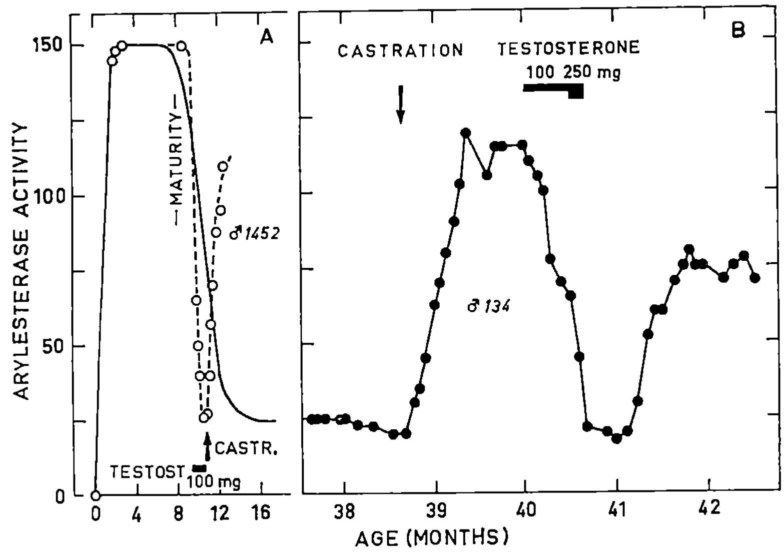

Fig 1 Effect of castration and testosterone propionate on plasma arylesterase activity of boars *in vivo*, the hormone was administered intramuscularly daily as indicated Esterase activity expressed in b_{30}/0 02 ml plasma with phenyl acetate as substrate (Warburg technique) *A*, solid line, variation in plasma arylesterase activity of boars from birth to adult age (generalization), broken line and open circles, effect of testosterone shortly after maturity and before castration of boar 1452 (phenotype 150, weight 140 kgm) *B*, effect of testosterone after castration of boar 134 (phenotype 150, weight 250 kgm)

In some cases, sows had higher esterase activity when sexually matured than two to three months before maturity It was observed that the activity was slightly higher shortly before partus, decreased below the normal value at the time of delivery, increased during 2–3 weeks after delivery and then again decreased to normal It is possible that these variations in activity are partly due to changes in volume of blood during pregnancy Œstradiol had no effect on the esterase activity in mature sows Testosterone had an opposite effect on this activity in sows compared with boars, that is, increase in esterase activity which, however, was not so marked as the decrease in boars

A New Unsaturated Uronide isolated from Alginase Hydrolysate

Alginase, which brings about the enzymic hydrolysis of alginic acid, has been found in the organs of a few of the lower animals[1,2] and in some kinds of bacteria[3,4]

According to Kooiman[5], and others[3,4], the enzyme of the bacteria can split alginic acid into smaller units and mannuronic acid monomers Recently, Eller and Payne[6] isolated a bacterium, *Alginomonas alginica*, which can oxidize mannuronic acid, but experiments concerning the isolation of the intermediates have not been reported During work on alginase hydrolysates we found a new type of mannuronide containing an unsaturated sugar acid and a mannuronic acid, the compound is the main component of the breakdown products of alginic acid The isolation and properties of this new compound are described here

One part of homogenized liver of abalone (*Haliotis discus hannai*) was mixed with 4 parts of distilled water at 4° C After 2 hr the mixture was centrifuged, and the supernatant filtered through pulp The clear water extract which was obtained was used as the enzyme solution 7 5 litres of 1 per cent sodium alginate solution were incubated with 750 ml of the enzyme solution at 30° C The *p*H value of the reaction mixture was adjusted to 7 0 with dilute sodium hydroxide during the course of the reaction Progress of the enzyme reaction was followed by noting the increase in reducing power, which was measured by the iodometric method of Somogyi[7] After 20 hr the reaction was stopped by the addition of sulphuric acid The precipitate was filtered off, and the filtrate neutralized with barium carbonate, re-filtered, and evaporated under reduced pressure below 40° C About 300 ml of the concentrate were passed through 'Amberlite *IR*-120' The neutralization with barium carbonate, filtration, and resin treatment were repeated, and the eluates and washing water combined. About 500 ml of the solution were put on a carbon–'Celite' column, 11 × 9 cm, and eluted with water, 10 per cent ethanol, and then 30 per cent ethanol The eluates were collected in 500-ml amounts at a flow-rate of 4 ml /min

The course of the separation on the column was checked by submitting the concentrate taken from each fraction to ascending paper chromatography in the systems *n*-butanol/acetic acid/water (5 2 3) and pyridine / ethyl acetate / acetic acid / water (5 5 1 3) According to the results of the chromatograms, individual fractions obtained from the column were pooled As the water fractions between 3 5 and 25 1 were observed to contain one main product of hydrolysis, they were combined, evaporated under reduced pressure below 40° C, and lyophilized Colourless needle-like crystals were isolated, with an approximate yield of 7 5 gm The crude product was recrystallized from water and had a melting point of 135 5–136·5° C (decomposed) (Calculated for $C_{12}H_{16}O_{12}\,H_2O$, C, 38 92, H, 4 86, found, C, 38 98, H, 5 22 per cent) An infra-red spectrum of this compound in potassium bromide showed two carboxylic groups The molecular weight was 400 ± 40 (Barger's method) This compound showed a strong absorption peak in the ultra-violet at 232 mμ (in water) with $E^{1\%}_{1\,\mathrm{cm}}$ of 143 0, which disappeared on bromination or palladium hydrogenation, indicating the presence of an α,β-unsaturated acid[8]. On paper chromatograms, significant differences between this and the brominated or palladium-hydrogenated compound were observed On hydrolysis with sulphuric acid at 100° C for 1 hr, the spots on chromatograms of the hydrolysates showed the characteristics of mannuronic acid and of mannuronic acid lactone, from which the occurrence of the mannuronic acid moiety in the compound can be inferred The colour reactions of this compound are shown in Table 1

Table 1 COLOUR REACTIONS OF THE UNSATURATED URONIDE

Reagent	Maximum absorption (mμ) or colour tone	Remarks
Carbazole*	530	Same as hexuronic acid
Phenol-H_2SO_4†	480	On bromination shows λ_{max} 480 and 560 mμ
Thiobarbituric acid‡	550	Same as pectin trans-eliminase hydrolysate§
Aniline hydrogen phthalate	brownish red	Same as hexuronic acid
o-Aminophenol	Yellow ⟶ brown	Differs from hexuronic acid which shows blue

§ Albersheim, P , Nuekom, H , and Deuel, H , *Helv Chim Acta*, **43**, 1422 (1960)

From these results it can be seen that the structure of this new type of uronide may be a diuronide containing $\Delta^{4,5}$-mannuronic acid and the mechanism of the enzyme action seems to involve the splitting of the glycosidic bond by an elimination reaction, thereby introducing unsaturation into the liberated molecules, as already seen in the splitting mechanisms of hyaluronic acid[8] and pectin[9]

Determination of the Amino-Acid Composition of Bovine Growth Hormone

THE amino-acid composition of bovine growth hormone has been determined[1] by Levy's method[2] This procedure which involves paper chromatography of dinitrophenyl derivatives of amino-acids is subject to certain limitations such as variable recoveries of tyrosine and lack of resolution of the leucine derivatives The development of automated ion-exchange chromatography of amino-acids[3] has prompted a re-investigation of the amino-acid composition of this protein

All the samples of bovine growth hormone employed in this work were furnished by Dr C H Li and were prepared by a previously described method[4] Determination of the nitrogen content of the anhydrous, ash-free protein by the Dumas method has given a value of 16 7 per cent in contrast to that of 15 8 per cent reported elsewhere[1] This value was confirmed by the amino-acid composition reported here and also by an independent analysis performed by the Elek Micro Analytical Laboratories, Los Angeles, California

Hydrolyses were carried out for 24 or 72 hr at 110° C in a sealed evacuated tube Approximately 4 mgm of protein was transferred to the tube in a weighing tube followed by 10 ml of constant-boiling hydrochloric acid redistilled in an all-glass system After hydrolysis, acid was removed by repeated evaporation, the hydrolysate was then diluted to 10 ml with 0·2 *N* citrate buffer, *p*H 2 2 Chromatograms of each hydrolysate were run in triplicate on a Spinco model *MS* amino-acid analyser

Table 1 gives the detailed amino-acid analysis of one bovine growth hormone sample, preparation III Appropriate corrections have been made for hydrolytic destruction Including the tryptophan and amide values of Li and Chung[1], it will be seen that the analysis will account for the weight of the protein and the nitrogen content A summary of the analyses for the three preparations is also shown in Table 1 Li and Chung's results[1] have been included for purposes of comparison Preparation I is from the sample of growth hormone used for the original analysis of Li and Chung It will be seen that the agreement is generally good There are two discrepancies worthy of note The total number of leucine and isoleucine residues obtained in the present analysis ranges from 62 to 68, the higher figure being found in two of the three preparations The older figure of 76 residues would appear to be subject to question In this work significantly higher values for serine have been obtained It is possible that this reflects a shortcoming in the Levy procedure The hydrolysis conditions might also be different to the extent that

Starch Gel Electrophoresis of Hen Egg White, Oviduct White, Yolk, Ova and Serum Proteins

THE Smithies[1] starch gel technique has recently been successfully applied by Lush[2] to demonstrate genetic polymorphism in proteins of the white of a hen egg

Lush[2] referred to two electrophoretically distinct components of crystalline hen ovalbumin described by me[3]. Three—and not two—components were reported in this work, which was later briefly reported[4] The electrophoretic technique used in an examination of hen serum and egg proteins is now described in more detail Suitable starch gels containing 15–17 per cent w/v starch were prepared from B D.H soluble starch and buffered as recommended by Smithies The 'Perspex' troughs containing the starch gels were placed on a metal sheet in contact with an ice block in a cold room at 0° The run was continued for 8 hr , at 400 V and 10 m amp

The components of the 'thin', 'inner thin and 'thick' layers[5] of hen egg white proteins were compared with those of the viscous fluid obtained from the magnum region of the oviducts of laying hens The protein composition appeared to be identical by comparison of pairs of these fluids on a single gel in all four cases Sixteen well-defined bands were observed (Fig 1*a*) The fast anodic components 16 15 . 14 were shown to be identical with three components of a sample of five-times crystallized ovalbumin, A_1 A_2 A_3 respectively, as described by Cann[6].

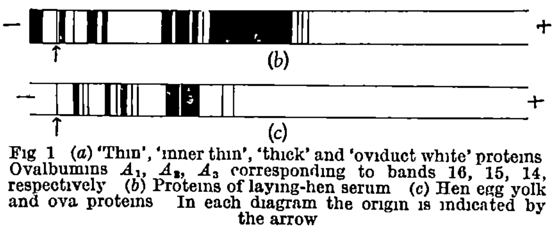

Fig 1 (*a*) 'Thin', 'inner thin', 'thick' and 'oviduct white' proteins Ovalbumins A_1, A_2, A_3 corresponding to bands 16, 15, 14, respectively (*b*) Proteins of laying-hen serum (*c*) Hen egg yolk and ova proteins In each diagram the origin is indicated by the arrow

For comparative purposes the protein patterns of hen serum (Fig 1*b*), egg yolk and ova isolated from the ovary (Fig 1*c*) are given The actual position of the bands in the figures cannot be directly compared since these patterns were obtained from different gels It can be seen that the high resolving power of starch electrophoresis is well suited to the study of species differences in complex protein and lipoprotein mixtures

Electrophoretic Separation of Conjugated Bilirubin on Paper

IN previous experiments[1] the 0 02 *M* phosphate buffer of *p*H 6 8 was used for electrophoresis of bile pigments on paper Under these conditions (in the absence of proteins) the conjugated bilirubin migrating anodically separates from the unconjugated bilirubin which remains on the starting line The presence of bile salts clearly influences this separation Purified preparations[2] of conjugated bilirubin which are devoid of bile salts migrate in the form of a tail beginning just from the starting line If bile salts are present a sharply defined zone of conjugated bilirubin separates, migrating in front of the bile salts The velocity of migration of this zone in the presence of bile salts is considerably higher than the rate of migration of pure preparations of the pigment.

For example, the purified preparation, containing about 80 per cent of pigment II (as determined according to Billing[3]) after paper electrophoresis (1 m.amp /1 cm of Whatman No 1 paper, potential gradient about 12·5 V /cm , 2 hr 15 min) in 0 02 *M* phosphate of *p*H 6 8, yielded a diffuse zone beginning at the starting line and tailing to 9 cm The same preparation in the presence of about 10-fold excess (on the weight basis) sodium taurocholate (and taurodeoxycholate) migrated simultaneously as a relatively narrow zone between 12 and 13 cm from the start The separation of both fractions of conjugated bilirubin (pigment I and pigment II[4]) could not be observed Analogous results were obtained with the use of sodium acetate–acetic acid buffer of *p*H 5·2, only the rate of migration was slightly lower Barbital buffer of *p*H 8 6 cannot be recommended owing to the instability of conjugated pigments in the alkaline range. The migration of unpurified preparations in this buffer proceeds in the same way as in phosphate buffers

For the purpose of electrophoretic separation of purified preparations of conjugated bilirubin (that is, those which were devoid of excess bile salts) the systems containing pyridine were tested Such systems were described by Grassmann *et al* [5] (*p*H 3 9) and by Runeckles and Krotkov[6] (*p*H 6 0) Both yielded better results than mere aqueous solutions, systems containing more pyridine caused less tailing The system (*p*H 6 1) was selected containing 5 ml of glacial acetic acid, 70 ml of pyridine in 1 litre Under

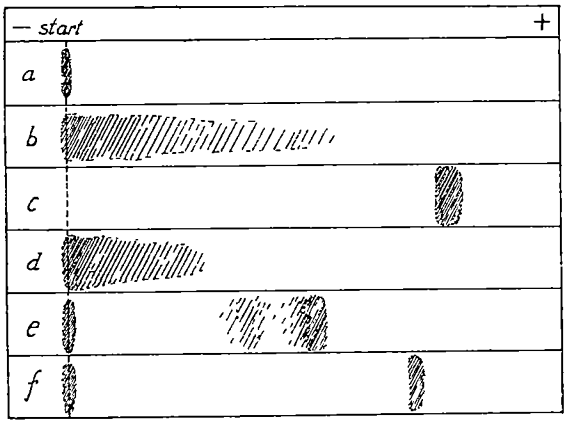

Fig. 1. Electrophoresis of bile pigments on filter paper. *a*, Unconjugated bilirubin in 0.02 *M* phosphate, *p*H 6.8; *b*, conjugated bilirubin (about 80 per cent of pigment II) in 0.02 *M* phosphate, *p*H 6.8; *c*, same in the presence of excess bile salts; *d*, same preparation as in *b* but in 0.08 *M* sodium acetate, *p*H 5.2; *e*, same preparation as in *b* with free bilirubin added, in pyridine acetate; *f*, same as in *e* in the presence of excess of bile salts

these conditions the separation of conjugated from unconjugated bilirubin was complete and both fractions of conjugated bilirubin were visible on the electrophoretograms if an appropriate amount of pigment was applied (corresponding to about 100 µgm of bilirubin on 2–3 cm width of paper). The presence of an excess of bile salts precludes the possibility of distinguishing between the two conjugated forms.

The use of buffers containing pyridine acetate enables the electrophoretic separation even of preparations devoid of bile salts, which was not possible in mere aqueous buffer solutions.

Enzymatic Hydrolysis of Biliary Conjugates of 3,4-Benzpyrene on Filter Paper

METABOLITES of numerous biologically active endogenous and exogenous organic compounds are excreted in bile and urine as glucuronic acid conjugates. In the course of studying the mechanism of action of carcinogenic polycyclic hydrocarbons, we wished to identify the metabolites of certain of these agents. For this purpose, ^{14}C-3,4-benzpyrene was injected into rats, and bile was collected by an indwelling cannula, utilizing a technique already described[1]. The bile fractions were collected in an automatic fraction collector, and enzymatic hydrolysis with β-glucuronidase was undertaken. Characterization of all the metabolites by this technique proved to be impossible because of the extreme instability of some of the hydrolysis products. We therefore attempted to determine whether the extent of oxidation and the class of conjugate formed could be established by direct analysis of the conjugates.

Two methods utilizing paper chromatography with subsequent enzymatic hydrolysis on paper were developed. Williams and Bevenue[2] have reported the use of a technique for the identification of raffinose and sucrose by enzymatic hydrolysis on paper chromatograms. In our work, migration was initially accomplished along one axis using a solvent system consisting of *n*-butanol/pyridine/water (3 : 2 : 2) for the separation of fluorescent compounds. If satisfactory separation resulted, the enzyme was applied to the individual spots, which were then incubated for 90 min. A second chromatographic separation of compounds in an axis perpendicular to the first was then done, using the same solvent system. Under these conditions, unhydrolysed conjugates were found lying on the diagonal across the paper while those undergoing hydrolysis were usually detected in greater proximity to the solvent front of the second migration.

When the number of metabolites was large or when separation in one dimension was unsatisfactory for further analysis, a two-dimensional chromatogram was prepared prior to application of the enzyme. The papers were then scanned for radioactivity in a two-dimensional scanner (Packard Instrument Co.), following which fluorescence spectroscopic analysis was used to characterize the metabolites. (In certain experiments, non-isotopic 3,4-benzpyrene and pyrene were used and qualitative results were then obtained exclusively by fluorescence analysis.)

Following two-dimensional chromatography, using *n*-butanol/pyridine/water (3 : 2 : 2) as the first solvent system and *n*-butanol / acetic acid / water (4 : 1 : 5) as the second, the individual spots were identified by fluorescence, following which they were incubated for 90 min with a solution containing 100 units of the enzyme. The spots were then cut out of the chromatogram and attached to a new paper strip for a third chromatographic separation for which either the original or the second solvent system was used. Excellent results were obtained by cutting two semi-circles in the fresh paper strip and slipping the cut-out spots into these slits in a manner which permitted satisfactory contact between the two papers. Following development of the chromatogram, the strip was analysed for fluorescent spectra and/or the presence of radioactive foci. By this technique data on the original compound, its conjugation, rate of hydrolysis, and stability and nature of the free parent substance were obtained. Wherever technically feasible, ultra-violet absorption spectroscopy was used in addition to fluorescence spectroscopy.

Basic information concerning the optimal conditions for enzymatic action on filter paper was obtained by studying the hydrolysis of phenolphthalein glucuronides (California Foundation for Biochemical Research) as suggested by Talalay *et al.*[3]. All work was carried out on Whatman No. 1 filter paper using 0.1 molar acetate buffer at *p*H 4.5. Time studies were performed in which a substrate containing 25 µgm phenolphthalein as the glucuronide and 100 units of the enzyme at 37° C were used. These were placed on a screen inside a still Dubnov incubator. These results are presented in Fig. 1, where they are further compared with results obtained following (*a*) substitution of a test-tube for the filter paper; (*b*) changing of the incubation temperature to 25° C;

(c) changing the concentration of phenolphthalein in the substrate to 5 μgm. It will be noted that, in the presence of 100 units of enzyme, 90 per cent hydrolysis occurred after 10 min. incubation at a concentration of 5 μgm. of substrate. In contrast, 60 per cent hydrolysis occurred at the five times greater concentration. As anticipated, a greater yield resulted from hydrolysis in a test-tube, and a lower yield was obtained when the temperature was reduced to 25° C.

Progressively increasing the enzyme concentration above 50 units per spot resulted in diminishing the rate of increase of hydrolysis, suggesting that 50 units of enzyme would provide an excess for all concentration ranges likely to be encountered (Fig. 2). The constant use of 100 units of enzyme in the presence of altered concentrations of the substrate resulted in a hydrolysis-rate of 100 per cent down to 60 per cent with the decreasing yield paralleling the increase in concentration of substrate (Fig. 3). At the concentration-range encountered in work on bile, that is, between 1 and 2 μgm. of metabolite, a yield of almost 100 per cent may properly be anticipated.

Our work has further established that hydrolysis does not occur if the enzyme is denatured, while little hydrolysis is noted when the strips are not perfectly free of solvent after chromatography. Hydrolysis was uniformly decreased in the presence of bile, and for this reason enzymatic hydrolysis was carried out only after chromatography in all cases. This emphasizes the need for enzymatic hydrolysis subsequent to chromatography. Hydrolysis of conjugates of oxidation products of benzpyrene does not occur as rapidly as the hydrolysis of phenolphthalein glucuronide, and therefore the hydrolysis time was increased to 90 min. in contrast to the 10 min. used for phenolphthalein. Detailed analysis of the biliary metabolites of polycyclic aromatic hydrocarbons will be presented in a subsequent publication.

PHYSIOLOGY

Respiratory Chain Phosphorylation in Sub-Cellular Particles isolated from the Hepatopancreas of *Carcinus maenas*

IN previous publications[1,2] I have shown that the respiratory chain present in respiring particles isolated from the hepatopancreas of *Carcinus maenas* (the common shore crab) contains pyridine nucleotides, flavoproteins and cytochromes c_1+c, b, a and a_3 in the proportions 19 3 1 1 1 1 All these respiratory pigments were shown to undergo oxidation and reduction during the oxidation of succinate, but the pyridine nucleotides reacted too slowly to be considered as a member of the respiratory chain associated with the oxidation of succinate This communication presents evidence which shows that the oxidations catalysed by this respiratory chain are associated with the production of adenosine triphosphate

The respiring particles used in these experiments were isolated by differential centrifugation of homogenates of hepatopancreas in 0 25 *M* sucrose[1] The P/O (phosphorus to oxygen) ratios associated with the oxidation of succinate, fumarate and α-oxoglutarate were measured using Warburg respirometers and an inorganic phosphate uptake method. The respiring particles were suspended in a reaction mixture containing 5 m*M* substrate, 5 m*M* magnesium chloride, 1 m*M* adenosine triphosphate, 5 m*M* phosphate buffer, *p*H 7·4 (10 m*M* for α-oxoglutarate), and malonate in the concentrations shown in Table 1 Sucrose was used to adjust the tonicity to 0 25 osmolar 0 9-ml samples of the suspension of respiring particles were placed in the main compartment of a 6-ml respirometer flask, 0 1 ml. of a 20 per cent potassium hydroxide solution was placed in the centre well and 0 1 ml of a 0 25 *M* glucose solution containing 4 mgm of crystalline hexokinase was in the side-arm of the flask After a 7-min equilibration period at 25° C the hexokinase–glucose solution was mixed with the contents of the main compartment and the oxygen consumption measured The reaction was stopped by the addition of 0 1 ml of a 40 per cent trichloroacetic acid solution The uptake of orthophosphate was determined as the difference between the orthophosphate contents of the experimental flasks and flasks to which the hexokinase was added after the trichloroacetic acid. Sumner's method[3] was used to assay orthophosphate. The results of these experiments are given in Table 1

Table 1 P/O RATIOS ASSOCIATED WITH THE OXIDATION OF VARIOUS SUBSTRATES BY THE RESPIRING HEPATOPANCREAS PARTICLES

Substrate	P/O ratio*	Qo_2 (μl /hr /mgm protein)*
Succinate	2 04 ± 0 32 (11)	29 9 ± 4 8 (10)
Fumarate	2 06 ± 0 46 (6)	18 7 ± 4 5 (6)
α-Oxoglutarate	2 72 ± 0 23 (7)	29 0 ± 4 8 (7)
+ 10 m*M* malonate	2 35 and 2 55	14 8 and 14 7
+ 30 m*M* malonate	2 07 and 1 89	12 0 and 11 9

* Data given as mean ± standard deviation (number of determinations)

The mean value of the P/O ratios allied to the oxidation of 4 5 m*M* succinate is 2 04 This value lies between those reported for rat heart sarcosomes, P/O ratio = 0 95, and for rat liver mitochondria, P/O ratio = 2 17 (ref 4) It should be noted that the P/O ratio associated with the oxidation of succinate by rat liver mitochondria is inflated by the phosphorylation associated with the further oxidation of the fumarate produced by the action of succinic acid dehydrogenase This would not appear to be the case in the respiring hepatopancreas particles, since the mean value of the P/O ratio associated with the oxidation of fumarate, 2 06, is only fractionally higher than that for the oxidation of succinate The P/O ratios for the oxidation of α-oxoglutarate by the respiring hepatopancreas particles is just lower than the value given by rat heart sarcosomes, P/O ratio = 2 80 ± 0 20 (10), in experiments where a similar method of assay to that described above was used (Beechey and Alcock, unpublished results) In experiments where the further oxidation of succinate was prevented by the addition of malonic acid, the P/O ratio associated with the oxidation of α-oxoglutarate was actually lowered It was 2 45 in the presence of 10 m*M* malonic acid and 1 92 in the presence of 30 m*M* malonic acid These results suggest that the malonic acid is acting as an uncoupling agent in this system

It was Loomis and Lipmann[5] who first demonstrated the uncoupling of respiratory chain phosphorylation from oxygen consumption by dinitrophenol The effect of dinitrophenol on the coupled oxidation succinate and fumarate by the hepatopancreas is shown in Fig 1 It can be seen that the complete uncoupling of phosphorylation from respiration occurs at concentrations of dinitrophenol greater than 60 μ*M* Thus the sensitivity of the phosphorylating mechanisms in these hepatopancreas particles to dinitrophenol is of the same order as that of the corresponding systems in mammalian liver mitochondria[6] and heart sarcosomes[7]

The results presented here show that the oxidation of succinate, fumarate and α-oxoglutarate by these respiring hepatopancreas particles is associated with the production of adenosine triphosphate and also

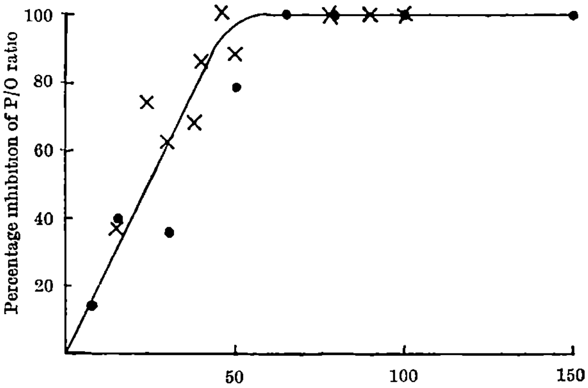

Fig 1 Effect of dinitrophenol on the P/O ratio associated with the oxidation of succinate (●) and fumarate (×) by the respiring hepatopancreas particles

that the phosphorylating mechanism is uncoupled by dinitrophenol. The P/O ratios measured are quite similar to those given by mammalian mitochondria These facts, together with the knowledge that these particles contain an active respiratory chain[1,2], suggest that respiratory chain phosphorylation occurs on these sub-cellular particles isolated from the hepatopancreas of *Carcinus maenas*

Growth Hormone Activity of the Anterior Pituitary Lobe of the Male Rat at Various Ages

WITHIN the past few years several reports have dealt with the relationship between the age of an animal and the pituitary content of growth hormone. Pigs[1,2], ox[3], and the rat[4,5] have been examined In general, it has been found that although the total amount of growth hormone in the pituitary gland increases greatly with age, the concentration of the hormone in the gland tends to remain fairly constant. The present work on the male rat supports this concept, but also indicates that relative to body-weight there may be a decreased amount of total growth hormone in the anterior lobe as the animal advances in age. This latter relationship has likewise been found in the larger species which have been examined, but previous evidence[5] on the rat has indicated a lack of correlation between the total pituitary growth hormone/body-weight ratio and age

Male rats of the Long-Evans strain which were raised in the Bucknell University colony were used predominantly as the source of the pituitaries which were assayed At ages of 10, 30, 60, 90, 180, 360 and 600 days the animals were killed by decapitation, the pituitary rapidly exposed, the posterior lobe removed and discarded, and the anterior lobe removed, weighed and placed in acetone. After 24 hr. in acetone the glands were air dried and placed in a vacuum desiccator until time for use At the time of assay the desiccated anterior lobes were weighed, homogenized in saline, and injected intraperitoneally into young hypophysectomized rats prepared as indicated below The homogenate, freshly prepared each day, was administered once daily for 4 days With the exception of two of the age periods, the injections were given to assay animals at three dosage-levels, namely, 80, 280 and 720 μgm of dry anterior pituitary a day Parallel injections of standard growth hormone were given to another three groups of hypophysectomized animals at dosage-levels of one-tenth the amounts of homogenate used Another group of animals received saline The 10- and 30-day-old pituitaries were injected at two levels only 80 and 280 μgm. per day for the 10-day-group, and 32 and 392 μgm daily for the 30-day pituitaries. For each of these two ages the growth hormone standard was likewise given in amounts equal to one-tenth the homogenate used Six to eight hypophysectomized rats were used at each dosage-level for all groups

The recipient animals used for each assay were albino male rats obtained from a commercial source at 22–24 days of age, and hypophysectomized when they were 28 days old At 40–42 days of age they were randomized into a number of groups and the four-day period of injection begun[6] Rats which had gained more than 8 gm or lost more than 3 gm post-operatively were eliminated from the assay The operated animals were maintained on calf meal, fresh bread, and 10 per cent glucose in their drinking water

Twenty-four hours after the last injection the rats were killed by ether anæsthesia and the tibias removed and prepared for epiphyseal measurement according to the procedure of Evans, Greenspan *et al* [7,8] Statistics were calculated according to methods given by Emmens[9]

It can be seen in Table 1 that the concentration of growth hormone activity in the anterior pituitary gland showed little change with age, the ranges of the estimated potencies being essentially the same for all groups In Table 1 are also given the anterior pituitary- and body-weights at the various ages examined, it will be noted that the ratio of dry (or wet) anterior pituitary-weight to body-weight exhibited a decrease with age The ratio was highest at 10 days and then dropped to a somewhat constant value for the ages up to 3 months A further decrease was observed at 6 months, and the still lower ratio seen at 12 months was maintained at 20 months of age Thus, with a rather similar concentration of growth hormone in the pituitary at all the ages investigated, these decreasing pituitary-weight/body-weight ratios would indicate that in the anterior pituitary gland there is less total growth hormone per gram of body-weight as the male rat ages

Solomon and Greep[5], using female rats, found that the growth hormone concentration in the whole

* Growth hormone potency of pituitary preparation and range of potency at 95 per cent significance level
† Number of pituitaries and number of animals weighed
‡ Desiccated pituitaries of a given age were weighed collectively, thus standard errors are not available
§ Standard error of the mean
¶ $P < 0\ 001$ that the difference between this value and that of any younger age group in this column is due to chance

pituitary likewise fluctuated within only a small range as the animals aged They observed in addition, however, that the weight of the whole pituitary continued to increase in an approximate proportion to the body-weight increments of the animals Therefore the total amount of pituitary growth hormone relative to body-weight was calculated to change very little, and showed neither a regular decrease nor increase throughout the age range studied Whether the apparent discrepancy between this latter observation and that of the present communication, in this regard, is due to the sex of the animal investigated or to anterior lobe and whole pituitary differences is not clear In support of the present results, it has been reported in both male and female pigs[1,2] and in the cow[3] that the total amount of growth hormone in the anterior lobe shows a decline in relation to body-weight as these animals age

It is recognized that the amount of hormone present in a gland may well not indicate the amount or rate of secretion, and information concerning blood-levels of, and tissue sensitivities to, growth hormone at various age periods would be of interest

The bovine growth hormone used as the standard was a gift of the Endocrinology Study Section of the National Institutes of Health This work was supported by National Science Foundation grant *G*–5069

Permeability of the Mammary Gland to Sodium-24, Potassium-42, Chlorine-36 and Iodine-131

Phosphorus-32 and calcium-45 appear in the blood of goats a few minutes after their administration through the teat[1,2] The regulation of milk electrolyte content is little understood, and it seems necessary to examine the problem of udder permeability further in order to understand these problems better

In the present investigation the permeability of the mammary gland to sodium-24, potassium-42, chlorine-36 and iodine-131 has been studied, using goats in the first half of lactation Polyethylene glycol (mean mol wt 4,000), which does not penetrate the udder epithelium[3], was used as a reference substance The disturbances in udder function, which often follow the injection of fluid through the teat, have been avoided so far as possible by reducing the injected amount of fluid The injected solutes are rapidly and fairly evenly distributed throughout the whole milk volume of the injected udder half[3].

Half of an udder was cannulated and about 2 ml physiological saline containing tracer (10–40 μc. of sodium-24, potassium-42 or iodine-131, 1–2 μc of chlorine-36) and polyethylene glycol was slowly injected, usually 4 hr after milking

In the experiments with iodine-131, 5-ml samples of milk were drawn at regular intervals, and the disappearance of iodide was examined by comparing the expansion of the iodide and polyethylene glycol spaces

In the other experiments the udder was cannulated some time after the injection and the milk collected in fractions When the milk ceased to flow spontaneously an additional amount of milk was obtained with oxytocin The volume of milk still left in the udder was calculated from the amount of polyethylene glycol retained in the udder.

The radioactive isotopes were counted in a Friesecke and Hoepfner *FH* 49, using an ordinary Geiger–Muller-tube for sodium and iodide and a proportional counter for potassium and chloride Polyethylene glycol was determined turbidimetrically[4]

The results from one experiment with iodine-131 are summarized in Table 1 Between the 4th and the 19th hr of the experiment the volume of water in the milk, measured as the distribution volume of polyethylene glycol, expands from 95 to 145 ml while the iodide space increases to nearly 5 litres during the same time

Table 1

Time after injection (hr)		4 5	6 3	8	9 8	11 3	19
Distribution volume (ml)	Polyethylene glycol	95	98	102	120	126	145*
	Iodine-131	265	346	447	875	1,192	4,606

* The goat used in this experiment was in an advanced stage of lactation, which explains the low production of milk

After the first 4 5 hr 40 per cent of the dose was still present in the udder This agrees well with the results from other experiments with iodide

The results of the experiments with sodium-24, potassium-42 and chlorine-36 are given in Table 2

Table 2

	No of experiments	Time between injection and sampling (hr)	Activity remaining in the milk (per cent)
Sodium-24	2	1	13
Sodium-24	2	4	1
Potassium-42	3	4	36
Chlorine-36	6	4	37
Sodium-24*	1	2	10
Chlorine-36*			70

* Examined simultaneously in the same udder half

It is evident that the sodium ions disappear far more rapidly than the others The difference between sodium and chloride is especially well demonstrated in the experiment where they were examined simultaneously

The ratio of the concentrations of the isotope and polyethylene glycol is usually lower in the last fractions of milk. Table 3 gives the results of one typical experiment with each isotope

Table 3

Fraction No	1	2	3	4	5	6	7	8
Sodium/PEG	38	33	30	27	29	7	7	
Potassium/PEG	21	20	19	18	16	16		
Chlorine/PEG	38	35	32	24	26	25	26	27

PEG, polyethylene glycol

Clearly the epithelium of the udder is fairly permeable to the ions examined, and Table 3 tends to show that this applies at least to the epithelium of the 'proximal' parts of the gland, that is, the finer ducts and the alveoli. More information is obviously needed before definite conclusions can be drawn with regard to the processes involved in the permeation of these solutes. In view of the low sodium content of the milk the apparently high permeability of the udder with regard to sodium ions may, however, indicate participation of both diffusion and active transport of this ion.

Particle-bound and Free Catecholamines in Dog Hearts and the Uptake of Injected Norepinephrine

Submicroscopic structures containing catecholamines have been found by high-speed centrifugation of homogenates or pressed juice of adrenal medulla[1-3], splenic nerves[4-6] and brain[7]. A granular fraction containing catecholamines has been isolated from the pressed juice of cyclostome hearts[8]. It was the purpose of this investigation to see whether also in mammalian hearts the catecholamines are stored in a particle-bound state; the question was also examined whether injected norepinephrine is taken up by submicroscopic cell elements. This is of interest since Raab and Gigee[9] reported a specific avidity of the heart muscle to absorb and store catecholamines.

Six puppy hearts, which have a high catecholamine content (Wegmann *et al.*, unpublished data), were submitted to successive low- and high-speed centrifugation after homogenization. The catecholamine content in the different fractions was analysed fluorimetrically. In another series of 7 animals an identical procedure was applied 20 min. after the intraperitoneal administration of 10 mgm. norepinephrine/kgm. The hearts were dissected into very small pieces in ice-cold physiological sodium chloride solution. After washing three times and re-suspending in ice-cold saline solution the hearts were homogenized in a Potter–Elvehjem glass homogenizer with a loose-fitting pestle. The homogenates were centrifuged at 600–1,000*g* for 10 min. The homogeneous supernatant was again centrifuged at 50,000–100,000*g* for 60 min. The sediment from this centrifugation was taken up in a few ml. of *N* hydrochloric acid. Both sediment and supernatant were then deproteinized by trichloracetic acid for fluorimetric estimation according to Euler and Lishajko[10] after adsorption on alumina and elution with acetic acid. Only a set of two filters (excitation at 412 mμ, emission at 508 mμ) was used; thus norepinephrine and epinephrine were determined together.

The catecholamine content in the different fractions of the normal hearts is shown in Table 1. The supernatant layer obtained by low-speed separation did not contain microscopically visible cell structures. After high-speed centrifugation 67–85 per cent (average 74.5 per cent) of the catecholamines were located in the small sediment.

The catecholamine content in the different fractions 20 min. after injection of 10 mgm./kgm. norepinephrine is shown in Table 2. In these experiments only 9–31 per cent (average 19.6 per cent) of the catecholamines were found in the sediment after high-speed centrifugation, the greater part being recovered in the supernatant. The difference between the results in the two series is highly significant ($P < 0.001$).

This investigation demonstrates the presence of particle-bound catecholamines in dog hearts. More than 95 per cent of injected norepinephrine found in the supernatant after low-speed centrifugation were not particle-bound. Whether or not these large amounts recovered in the soluble fraction were intra- or extra-cellular cannot be stated at the present time.

Response of the Reticulo-Endothelial System to Stimulation with Œstrogens

We have previously shown that diethylstilbœstrol and tri-*p*-anisylchloroethylene are strong stimulants of the reticulo-endothelial system[1]. We have also found that when the reticulo-endothelial system is stimulated by diethylstilbœstrol the body defence is raised, as indicated by increased phagocytic activity, elevation of the serum γ-globulin to about three times the normal level, increased antibody formation, and the protection of mice and guinea pigs against lethal doses of virulent bacteria. In previous experiments it was found that the minimum dose of diethylstilbœstrol required to stimulate the reticulo-endothelial phagocytes is about a hundred times greater than that necessary to induce œstrus[2] and that after treatment with 0.5 mgm. diethylstilbœstrol daily for 6 days the phagocytic activity returns to normal about 8 days later[3]

The present work was carried out to ascertain (1) the speed of action of diethylstilbœstrol and tri-*p*-anisylchloroethylene in stimulating the reticulo-endothelial system, (2) whether this stimulation is maintained during repeated treatment with diethylstilbœstrol

In the following experiments the phagocytic activity was taken as the measure of stimulation of the reticulo-endothelial system, it was assessed by the rate of disappearance of a known amount of specially prepared carbon from the circulating blood, the method being a modification of that of Biozzi *et al*[4] The procedure used has been described in previous communications[5] The total body phagocytic activity or phagocytic index is denoted by the symbol *K*

*Speed of action of diethylstilbœstrol and tri-*p*-anisylchloroethylene* Fifty-five male white mice (*T O* Swiss strain) of 20–25 gm body-weight were used in this experiment Fifteen animals each received 0 1 mgm diethylstilbœstrol in 0 1 ml arachis oil subcutaneously once daily, fifteen received 0 5 mgm diethylstilbœstrol in 0 1 ml arachis oil subcutaneously once daily, and a further fifteen received 1 mgm tri-*p*-anisylchloroethylene in 0 2 ml olive oil orally once daily On the first. second and third day after the commencement of treatment with each compound the phagocytic activity was measured in groups of 5 animals by the carbon method referred to above Ten animals were used as controls and received no treatment

The results are shown in Table 1 The control animals showed a phagocytic index of 15 ± 2 Compared with the control values it can be seen that on the first day after the commencement of treatment with each of the compounds there is slight stimulation of the reticulo-endothelial system, by the second day there is moderate stimulation, and by the third day the system has become strongly stimulated

Effect of repeated treatment with diethylstilbœstrol Forty male white mice (*T O* Swiss strain) of 20–25 gm body-weight were used in this experiment Ten of the animals were used as controls and received no treatment The remaining 30 animals were divided into three groups of 10 and were treated as follows Group *A*, 10 animals each received 0 5 mgm, diethylstilbœstrol in 0 1 ml arachis oil subcutaneously once daily for 6 days On the eighth day after the commencement of treatment the phagocytic activity was measured in each animal by the carbon method, and the animals were then killed Group *B*, 10 animals were given diethlystilbœstrol for 6 days, as described above They were then left for 3 weeks, then given a second course of diethylstilbœstrol for 6 days, on the following day the phagocytic activity was measured in each animal, then the animals were killed Group *C*, 10 animals were given a similar course of diethylstilbœstrol for 6 days They were left for 3 weeks then given a second course of diethylstilbœstrol for 6 days, they were now left for a further 3 weeks then given a third course of diethylstilbœstrol for 6 days On the following day the phagocytic activity was measured in each animal and then the animals were killed

Table 1 SPEED OF ACTION OF DIETHYLSTILBŒSTROL AND TRI-*p*-ANISYLCHLOROETHYLENE IN STIMULATING THE RETICULO-ENDOTHELIAL SYSTEM

Compound used	Daily dose	Day after treatment commenced	Mean phagocytic index (*K* value) ± *S E*
Diethylstilbœstrol	0 1 mgm in 0 1 ml arachis oil subcutaneously	First	18 ± 1
		Second	37 ± 4
		Third	40 ± 1
Diethylstilbœstrol	0 5 mgm in 0 1 ml arachis oil subcutaneously	First	19 ± 1
		Second	33 ± 7
		Third	72 ± 4
Tri-*p*-anisylchloroethylene	1 0 mgm in 0 2 ml olive oil orally	First	25 ± 1
		Second	37 ± 2
		Third	60 ± 4
Controls			15 ± 2

Table 2 EFFECT OF REPEATED TREATMENT WITH DIETHYLSTILBŒSTROL ON PHAGOCYTIC ACTIVITY OF RETICULO-ENDOTHELIAL SYSTEM

Animal group	Mean phagocytic index (*K* value) ± *S E*
Group *A*	66 ± 3
Group *B*	58 ± 1
Group *C*	77 ± 1
Controls	16 ± 1

The results are shown in Table 2 The control animals showed a phagocytic index (*K* value) of 16 ± 1 Compared with the controls it can be seen that the total phagocytic activity or phagocytic index *K* remains high in all three experimental groups *A*, *B* and *C* and that the phagocytes continue to respond to stimulation during repeated treatment with diethylstilbœstrol

The above results show that œstrogen treatment produces strong stimulation of reticulo-endothelial activity by the third day after the administration of the drug is commenced When the treatment is stopped the stimulative effect lasts for about 1 week, during which it gradually diminishes, and by the eighth or ninth day the phagocytic activity has returned to normal[3] These findings may be of clinical interest since they indicate the short period during which œstrogens need be used to raise the body defence in acute illness The results also indicate that the reticulo-endothelial phagocytes continue to respond to stimulation during repeated courses of treatment with diethylstilbœstrol over a period of at least 9 weeks

Production of Aortic Occlusion resembling Acute Aortic Embolism Syndrome in Cats

A SYNDROME of acute aortic embolism occurring in cats resembles the condition found in man An embolus, usually fragmented from an intracardiac thrombus, lodges at the iliac bifurcation, disrupting blood supply to the rear limbs The symptoms include paraplegia, loss of femoral pulse, cold rear extremities, initial muscular tenseness of the rear limbs followed by atrophy, and pain In an effort to reproduce the signs of aortic embolism or 'saddle embolus', the posterior aortas of thirteen cats were occluded by various methods The work here suggests that the blood-clot occluding the aorta is responsible for the hind-limb paralysis, accomplishing this by some means other than mechanical circulatory blockage.

Experimental aortic ligations have been performed frequently on laboratory animals, many being concerned with occlusion of the aorta above the renal arteries[1,2]. According to Adams[3], suprarenal aortic occlusion causes paralysis by ischæmic damage to the spinal cord, whereas infrarenal aortic occlusion accomplishes this by peripheral nerve damage. Giuseffi[4] states that infrarenal aortic occlusion of more than 4 hr. is apt to produce paraplegia in the dog. In his work on dogs, Brooks[5] reports that there is a constant marked disturbance in function of the posterior extremities following ligation of the aorta between the inferior mesenteric and external iliac arteries.

Long-term infrarenal aortic ligation work on the cat is not readily found in the literature. Because clots were found at the iliac bifurcation in naturally occurring cases, these experiments were designed to look into the effects of low aortic ligation on symptomatology referable to the rear limbs.

Cats between the ages of 7 months and 5 years were divided into 3 groups according to the surgical procedure used on each. A pre-surgical aortogram was performed on every cat to determine patency of the aorta. Braided stainless steel wire or heavy silk was used as the ligature material.

Group 1 consisted of five cats in which a single ligature was placed around the aorta at the level of the iliac bifurcation. Complete occlusion of the aorta was determined by aortography immediately after surgery. From the day following ligation until they were killed one month later, these cats showed no symptoms of paraplegia. Subsequent aortograms demonstrated a progressive increase in collateral circulation at the ligation site. Although no femoral pulse could be palpated post-surgically, the rear legs remained warm.

Group 2 consisted of five cats which were ligated as above with a second ligature placed approximately 1·5 cm. proximal to the first ligature. In most cases the circumflex iliac arteries were also ligated since they were the only vessels emerging from the aorta between the two aortic ligatures. As in Group 1, these cats demonstrated no symptoms of paraplegia. The purpose of the double ligation was to determine whether or not a 1·5 cm. 'dead space' in the aorta would cause a slower build-up of collateral circulation than a single ligature. Results did not differ from Group 1.

Group 3, in which a clot was produced in the posterior aorta of three cats, was done in order to simulate the naturally occurring syndrome of aortic embolism. A permanent ligature was placed around the aorta at the iliac bifurcation as in Group 1. The circumflex iliac arteries were obliterated as in Group 2. A length of umbilical tape was then placed around the aorta 1·5 cm. above the first ligature to occlude the aorta temporarily. When the tape was drawn snugly, blood was trapped between the ligatures. 10–20 units of bovine thrombin (about 0·2 c.c. of fluid) was injected through a 27-gauge needle into the lumen of the aorta between the ligatures. After allowing 5 min. for a clot to form, the temporary tape ligature was removed. On the day after surgery all three cats were paralysed in the rear limbs. Sensory and motor functions were lacking. There was no femoral pulse and the rear limbs were cold to the touch. Muscle atrophy of the rear limbs was extensive at the end of one week. Aortography showed no increase in collateral circulation. After ten days of unabated paraplegia, all three cats were killed. In contradistinction to Groups 1 and 2, necropsy showed a small, ragged clot extending approximately 1 cm. above the ligature at the iliac bifurcation. The muscles of the rear limbs were pale in colour. There were no gross lesions of the spinal cord or peripheral nerves to the rear limbs.

The following conclusions are drawn from this preliminary study: (1) ligation of the aorta of the cat at the iliac bifurcation has no demonstrable effect on locomotion in spite of the diminution of femoral pulse, and (2) since the methods used in Groups 1 and 2 produced no paretic symptoms but the Group 3 method did, the clot apparently played some part in causing the paraplegia. Collateral circulation was evidently impeded in some way by the presence of the clot. It is doubtful whether this happened by mechanical blockage of collateral channels from the aorta since the clot extended up the aorta from the iliac bifurcation for only a short distance. In fact, the clot did not extend as far up the aorta as the proximal ligature in Group 2. The similarity of the symptoms of naturally occurring and experimentally produced aortic embolism is striking and leads us to believe that the mechanism involved in producing paraplegia is the same in both instances.

RADIOBIOLOGY

Mast Cell Turn-over in Adult Mice

Mast cells are generally thought to be derived from undifferentiated mesenchymal cells and perhaps heteroplastically from lymphocytes, plasma cells or histiocytes[1]. Various conditions can cause mast cell granules to be discharged in a manner that has led some investigators to believe the cell is destroyed in the process. Yet Padawer[2] reported never having seen a mast cell in mitosis during his extensive investigation of these cells with colchicine and related substances. This does not preclude the possibility of mast cells being continually replaced by transformations from a population of proliferating precursor cells. Extensive mast cell degranulation occurs after administration of compound 48/80 and is followed within 4 days by the re-appearance of granulated mast cells[3]. This sequence of events was investigated radioautographically with sulphur-35 by Watson and Kennedy[4]. They observed sulphur-35 uptake within 24 hr. by 'ghost cells' which had a tissue distribution equivalent to that of the original granulated mast cells.

The question of mast cell turn-over has been investigated in the present experiment by using radioautography after repeated injections of tritiated thymidine because this method will detect cells synthesizing deoxyribonucleic acid (DNA) even if they represent only a very small fraction of the population, and because transformations to mast cells from a proliferating population of precursor cells would be detected through the gradual accumulation of labelled nuclei in the mast cell population.

Six adult, female, strain *A/Jax* mice were given 6 injections of 100 µc tritiated thymidine at 4-hr intervals and killed at 1, 2, 3, 4, 8, or 21 days after the initial injection Tissues were fixed in Carnoy's fluid and processed for radioautography using a fluid emulsion method described elsewhere[5] with the modification that a 'Celloidin' coating over the sections was omitted The radioautographs were developed after exposing for a month and then stained with aldehyde-fuchsin[6] or toluidin blue (0 01 per cent aqueous solution followed by air drying and immersion in 95 per cent alcohol) or hæmatoxylin and eosin Mast cells and radioactive connective tissue cells were counted in one aldehyde–fuchsin-stained section from each time-interval for the three areas of connective tissue

Table 1 FREQUENCY OF RADIOACTIVE AND NON-RADIOACTIVE MAST CELLS AND OF RADIOACTIVE CELLS FROM OTHER CONNECTIVE TISSUE CELL POPULATIONS IN ALDEHYDE–FUCHSIN-STAINED RADIOAUTOGRAPHS

Tissue	Days after injection	Mast cells Radio-active	Mast cells Non-radioactive	Other cells radio-active	Area (sq mm.)
Skin	1	0	20	84	7 05
	2	0	21	38	3 37
	3	0	57	140	8 66
	4	0	77	112	7 92
	8	0	85	27	10 08

Foot-pad	1	0	6	16	0 88
	2	0	10	54	2 70
	3	0	122	33	15 30
	4	0	8	7	0 83
	8	0	9	11	0 59
	21	1	110	11	5 50
Tongue	1	0	10	7	1 64
	2	1	64	6	5 23
	3	1	58	6	3 74
	4	0	8	12	5 51
	21	0	33	3	4 22
Totals		3	724	590	85 66

The use of aldehyde-fuchsin, which left the nuclei unstained, made it easy to identify silver grains over a nucleus, and facilitated the locating of mast cells by providing a specific stain for their cytoplasm Slides stained with toluidin blue or hæmatoxylin and eosin were scanned as a further check on the mast cell population and to identify the various radioactive cells in the connective tissue Counts of non-radioactive and radioactive mast cells and radioactive connective tissue cells in aldehyde–fuchsin-stained sections are given in Table 1 Radioactive mast cells were rare in these tissues, regardless of the time-interval Radioactive cells were plentiful in other cell populations of the connective tissue, many radioactive fibrocytes, macrophages, neutrophils, lymphocytes and plasma cells were seen

Considering the frequency of radioactive nuclei among proliferating cell populations seen in radioautographs of adult mice given single[7] or multiple[8] injections of tritiated thymidine, the mast-cell population sampled in this work was obviously very stable in terms of cell turn-over. If the multiple injections labelled all cells dividing during the 24-hr period, then it would take 9–18 months to replace completely a population in which only three cells out of 727 were found labelled after the 24-hr injection period The three radioactive mast cells listed in Table 1 may represent transformations rather than DNA synthesis by mature mast cells Radioactive cells which might serve as mast cell precursors were abundant in the areas where mast cells were found (Table 1) Yet, formation of mast cells could not have been the principal objective of mitotic activity in any of these cell populations (including their stem cells) since the number of radioactive fibrocytes, macrophages, lymphocytes and plasma cells was greatly in excess of the number of radioactive mast cells The frequency of radioactive leucocytes varied with time as would be expected[8], and decreased greatly at the later time intervals

Detection of Inclusion Bodies containing Deoxyribonucleic Acid by Means of Autoradiography

WE have been examining extensively the *in vitro* multiplication of oil-induced, rabbit peritoneal histiocytes by means of autoradiography The cells were incubated on flying coverslips in Leighton-tubes, containing 40 per cent homologous serum in Tyrode solution in the presence of 1 µc tritiated thymidine/ml In general, little incorporation occurred within the first 48 hr, but then an increasing number of cells became labelled

In our first experiments all the label was localized in the nucleus, the cytoplasm remaining free (even in autoradiographs exposed for 6 months) However, in several rabbits which were bought from the same breeder we noticed the presence of a cytoplasmic inclusion body, a finding later closely paralleled in time with the occurrence of a non-bacterial peritonitis The shape of the inclusion body was that of a star (Fig. 1), and it was quite regular

This cytoplasmic label appeared irrespective of that of the nucleus The percentage of histiocytes containing these 'inclusion bodies' increased with time in cell culture The number of cells containing 2 or 3 bodies in the same cell was also increased

Table 1 presents quite typical data where several hundred cells were scored for each time period

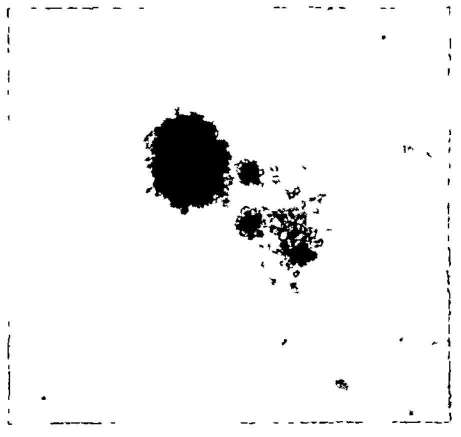

Fig 1. Cytoplasmic inclusion bodies labelled with tritiated thymidine in rabbit histiocyte

Table 1 INCREASE WITH AGE OF TRITIATED CYTOPLASMIC INCLUSION BODIES IN RABBIT HISTIOCYTES

Time (hr)	Percentage of histiocytes labelled
3	0
24	0
48	4
72	9
96	12

It is suggested that autoradiography could be a useful and sensitive method for detection of cytoplasmic parasites containing deoxyribonucleic acid which are in the latent stage but in which turn-over of deoxyribonucleic acid is occurring

HÆMATOLOGY

Fœtal Hæmoglobin in Fanconi Type Anæmia

THE persistence of fœtal hæmoglobin formation after infancy is usually taken to indicate an anæmic state existing from early life and is most commonly found in association with hereditary hæmoglobinopathies Despite an extensive search among other types of anæmia only very slight increases have been found, with the exception of quite large amounts present in acute leukæmia in children[1] and in adolescents[2]

A further example of an anæmia developing long after infancy which is also associated with an increased amount of hæmoglobin *F* has been found in a 9 yr old boy suffering from Fanconi-type anæmia This child had been under observation from the age of six months because of his poor physical development and the fact that he had congenital deformities of both thumbs Before the age of 9 yr the hæmoglobin was estimated to be 10 4–11 gm /100 ml on three occasions, but at this age a severe anæmia developed with a hæmoglobin of 5 3 gm /100 ml which was associated with a fœtal hæmoglobin-level of 14 per cent The hæmoglobin-level was raised by transfusions and, as a result of treatment with methyl testosterone and prednisone as described in ref 3 this level was maintained for six months, during which time the level of hæmoglobin *F* fell to 6 4 per cent At this point the testosterone was discontinued because of its adverse side-effects and this has resulted in a progressive fall in the level of hæmoglobin to 7 4 gm /100 ml over the last eight months associated with a rise in the level of hæmoglobin *F* to 10 7 per cent

This apparent variation in levels of hæmoglobin *F* with the total amount of hæmoglobin present suggests that in certain circumstances children, as well as neonates, react to anæmia by the production of hæmoglobin *F*, particularly as it would appear that no significant degree of anæmia was present in this case during the first nine years of life

There is, however, an alternative possibility that, as production of hæmoglobin *A* is under different genetic control from hæmoglobin *F*, its presence here is due to a genetic abnormality associated with the other genetic abnormalities occurring in this condition It is interesting to note in regard to the earlier finding of hæmoglobin *F* in acute leukæmias that there are on record three instances of Fanconi's anæmia and leukæmia occurring among different members of the same family[4], a remarkable association in view of the rarity of Fanconi's anæmia.

Agglutination and the Electrical Surface Potential of Red Blood Cells

THE reduction of the electrical surface potential of erythrocytes has been considered for a long time as a possible cause of cell agglutination

Certain colloids coagulate only after decrease of their surface potential below a certain critical value The same was found for bacteria, the cause of both clumping and electrical discharge being either antibody or acidification[1,2] Similarly, erythrocytes have been observed repeatedly to show a reduced surface potential after treatment with antibody or with other agglutinating agents

This communication reports measurements of the surface potential of erythrocytes after treatment with one of the following agglutinating substances iso-antibodies, immune antibodies, agglomerins[3] (specific proteins in plasma of blood with high sedimentation-rate), certain salts and hæmagglutinating viruses The effects of non-agglutinating (incomplete) antibodies on the surface potential have also been investigated

A modified Abramson cell electrophoresis apparatus which was adapted for small volumes of test solution (2 0 ml) was used This modification permits investigation of suspensions in either salt solutions or protein solutions

After applying a current of 10 0 m amp , the velocities of single cells were observed with the microscope in one of the stationary planes of the electrophoresis cuvette and measured by means of a stop-watch and an ocular micrometer calibrated in microns 10 determinations were made of each sample and the arithmetic mean calculated The velocities were corrected for field strength (V /cm) and viscosity The mobility values were taken as a measure of the electrical surface potential of the cells

The buffer for diluting most agglutinating materials was a 0 9 per cent sodium chloride solution which contains 5 volumes per cent of $M/15$ phosphate buffer The final *p*H was 7 2 The (anodic) mobility of human red blood cells in this buffer was 1 080 ± 0 008 μ/sec /V /cm

All measurements were carried out directly in the appropriate test solutions, adequate time and temperature for incubation being allowed By this method, the effect on agglutination and surface potential of the medium itself was taken into account The erythrocyte concentration was 0 1 per cent

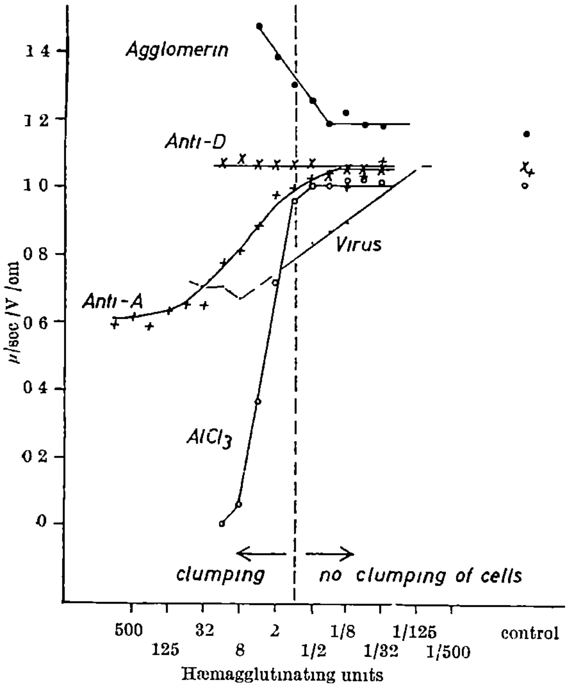

Fig. 1. Electrophoretic mobility of human erythrocytes after treatment with agglutinating agents. Dilutions in geometric progression in phosphate-buffered saline (anti-*A*, anti-*D*, virus), non-buffered saline (aluminium chloride) or compatible normal plasma (agglomeration of blood with high sedimentation-rate)

Following the measurements, the suspensions were recovered and tested for agglutination after 2 min. of centrifugation at 150*g*. In addition, the specific electrical resistance and the viscosity of the supernatant liquids were determined. All measurements including cell electrophoresis were carried out at 23.0° C. Dilutions of all materials in geometric progression in standard buffer were prepared. The highest dilution which gave a macroscopically detectable agglutination was taken as the titre of the solution and was assigned a value of one hæmagglutinating unit.

Typical results are shown in Fig. 1, which indicates that anti-*A* isoagglutinin caused a marked decrease of the electrophoretic velocity of the erythrocytes. However, the effect was small at the concentration at which agglutination began. This behaviour differed from that of hæmagglutinating virus (fowl plague, inactivated by sodium periodate), where a much higher reduction of cell mobility still did not alter the stability in suspension of the blood cells. Anti-*D* had no effect and the electrophoretic mobility remained unchanged even after addition of 32 hæmagglutinating units. Complete and incomplete anti-*D* were electrophoretically similar. The agglomeration of the red blood cells by plasma from a patient with a high sedimentation-rate was accompanied by increase in electrophoretic mobility of the cells. In this case the dilution was carried out with compatible normal plasma. A hæmagglutinating salt (such as aluminium chloride) had a profound effect on cell mobility. No electrophoretic effects were observed on erythrocytes with compatible blood groups. The results will be published later in greater detail.

In summary, the present work indicates several possible relationships between agglutination and surface charge: (1) both agglutination and reduction of the electrophoretic mobility of erythrocytes (like virus); (2) agglutination and no reduction (anti-*D* in saline acting), (3) no agglutination in saline but reduction (special anti-erythrocyte-rabbit sera), (4) no agglutination in saline and no reduction (anti-*D* in albumin acting), (5) increase of mobility in combination with cell agglomeration (plasma of high sedimentation-rate).

Serum β-Globulin Types in Red Deer and Other Species and their Stability in the Presence of Bacteria

INDIVIDUAL variations in the serum β-globulin patterns obtained on starch-gel electrophoresis have been shown to be genetically determined in a number of species[1-5] and in some the proteins concerned have been shown to be transferrins[7,8]. These variations have been ascribed to a number of alleles[5,6] which have been used in the genetic characterization of animal populations[2,3,7]. This communication reports the serum β-globulin patterns found in red deer (*Cervus elaphus*) with some observations and experiments on their stability, shows that they are due to transferrins and makes some comparisons with the β-globulin patterns in other species.

Serum samples of *C. elaphus* were obtained through several culling seasons from around Braemar, by courtesy of the Mar Estate, and from Rhum, a national nature reserve. A few samples of fallow deer (*Dama dama*) and Sika deer (*C. nipon nipon*) were obtained from parks in Kent. The blood was collected at death and the serum separated before posting to the Rowett Research Institute, where it was stored at + 1° C for examination. Starch-gel electrophoresis was carried out in phosphate buffer *p*H 7.6 (ref. 9) using hydrolysed starch (Connaught) and paper electrophoresis in 0.05 *M* barbiturate buffer *p*H 8.6 (ref. 5). Transferrins were detected by radioautographs[7] of both starch gel and paper electropherograms of sera to which iron-59 had been added.

The β-globulin zones in *C. elaphus* were found to occupy five possible positions showing a regular decrease in mobility, on starch-gel electrophoresis. Calling these zones *a*, *b*, *c*, *d* and *e*, 254 samples showed patterns of types *ab*, *abc* or *bc*. Six samples showed slower-moving zones of type *cd* or *cde* and two samples showed atypical patterns in which three zones occurred in the region of zones *ab*. Twelve samples of *Dama dama* and five of *C. nipon nipon* were all type *bc*: the zone *b* corresponded to the single β-globulin zone (transferrin) of a human serum. Some examples of the different types of sera are shown schematically in Table 1 and their distribution in *C. elaphus* is given in Table 2.

The samples of *C. elaphus* for the first two seasons were re-examined after storage for several months at + 1° C., when it was found that seventeen of them had changed their type, showing slower-moving zones; this change was also detectable on paper electrophoresis. As an example, five samples of type *ab* become type *cd*. In the subsequent season, care was taken to use a preservative ('Thiomersal', British Drug Houses, Ltd.) in the sample bottles and no

Seasons 1958–61	33	14	2	—	—	49
Samples from Rhum						
Seasons 1958–60	41	36	8	6	1	92
Season 1960–1 (stags)	35	23	2	—	—	60
(hinds)	32	25	3	—	1	61
All seasons	108	84	13	6	2	213

slow-moving types were found Comparison of the two lots of sera showed that the stored samples had often supported a considerable growth of Gram-positive and negative streptococci and bacilli, accompanied by a slightly more acid reaction

An attempt was made to produce changes in the β-globulin patterns experimentally by inoculating fresh sera with stored sera from the previous season Incubation for 24 hr. at 37° C produced bacterial growth but no changes in pattern, however, on subsequent standing at + 1° C. for four weeks, slower-moving zones appeared and this did not occur in uninoculated control sera Examples of the changes that can be produced in *C elaphus* and in human sera are included in Table 1.

Experiments with iron-59 were carried out on various sera to see if the β-globulin patterns being studied were due to transferrins The radioautographs showed that the zones *a*, *b* and *c* in *C elaphus* and *b* and *c* in *Dama dama* and in *C. nipon nipon* and the slow-moving zones *c*, *d*, and *e* in *C elaphus* samples altered on storage were the only ones in the sera combining with iron This was also found to be true of the strong zones characterizing eight sheep, six cattle and three goat-type sera that have been described[2-4] The radioautographs of the paper electropherograms confirmed that the proteins studied were β-globulins in all the species mentioned

It would seem that the various β-globulin types that have been reported are due to transferrins and that these proteins can readily show a stepwise decrease in mobility, comparable to the differences observed between individual types and without affecting the ability of the protein to combine with iron As the decreased mobility is detectable on paper electrophoresis, the changes are probably due to a decreased negative charge rather than to a gel filtration effect on a system of polymers A possible explanation of these changes is suggested by the report of Schultze[10] that the bacterial enzyme neuraminidase reduced the electrophoretic mobility of a number of human serum proteins. It would appear advisable, therefore, to accept with caution, as genetic types, rare slow-moving zones, in samples obtained under primitive conditions, unless such changes can be excluded and the type confirmed by a fresh sample from the same individual.

We are grateful to G Macnaughton, M Douglas, P Macrae, L Stewart and G Mackay, of the Nature Conservancy, and J. Bonner-Williams, of Tonbridge, for help in obtaining samples of deer sera, and to Dr G. C Ashton for the sheep and cattle type sera

Amino-Acid Composition of the Polypeptide Chains of Gorilla Hæmoglobin

COMPARISON of tryptic peptide patterns has demonstrated the great overall similarity of the primary structure of hæmoglobins from normal adult man and anthropoid apes[1]. Work is now in progress to define this similarity more precisely. We report here the determination of the amino-acid composition of the polypeptide chains of gorilla hæmoglobin

Recent investigation in these laboratories has shown that gorilla hæmoglobin contains two pairs of polypeptide chains These have the same *N*-terminal sequence by the dinitrophenyl method as the polypeptide chains of human hæmoglobin[2,3] We designate them, therefore, the α- and β-chains

The α- and β-chains of gorilla hæmoglobin were separated by chromatography according to the method of Wilson and Smith[4] Individual chains were hydrolysed in 6 *N* hydrochloric acid at 110° C for 22 and 70 hr The amino-acid composition was determined by means of a Spinco automatic amino-acid analyser

The results are given in Table 1

On the basis of the amino-acid composition, the α- and β-chains of gorilla hæmoglobin are almost indistinguishable from the corresponding chains of human hæmoglobin The α-chain of gorilla hæmoglobin appears to have one more residue of aspartic acid and one less residue each of glutamic acid and serine Amino-acid analysis of tryptic peptides from the α-chain has revealed the substitution of an aspartyl for a glutamyl residue in a peptide equivalent to spot No 23 (ref 8) or peptide αT-4 (ref 9) of the α-chain of human hæmoglobin Assuming an essentially identical sequence in the two types of α-chains, this substitution probably is in the 23rd residue from the *N*-terminus Whether the α-chain of gorilla hæmoglobin actually contains one less seryl residue is uncertain because of the destruction of serine during hydrolysis The value given, however, was obtained from each of two independent determinations of the destruction of serine as a function of the time of hydrolysis

The β-chain of gorilla hæmoglobin clearly contains one less arginyl residue than that of human hæmoglobin and may contain an additional lysyl residue

Table 1 Number of Residues per α- and β-Chain of Gorilla and Human Hæmoglobins

* Based on refs 5 and 6 for the α-chain, on ref 7 for the β-chain, and on a personal communication from G Braunitzer

† Estimated from the tryptic peptide pattern and from the ultraviolet spectrum.

In the hydrolysates of the β-chain, homocitrulline was found Presumably, this was formed by reaction of lysine with cyanate[10] in the urea which was used in the separation of the chains although its formation would not have been anticipated because of the acidity of the solutions The value for lysine in the β-chain thus is reported as the sum of lysine and homocitrulline

These amino-acid compositions thus yield further evidence of the similarity of gorilla and human hæmoglobins The substitution of an aspartyl for a glutamyl residue in the α-chain and the possible substitution of a lysyl for an arginyl residue in the β-chain are compensatory in charge in each chain. As a result, the electrophoretic behaviours should be alike. Indeed, migration-rates of the two hæmoglobins on paper electrophoresis at *p*H 8 6 are indistinguishable (Paper electrophoretic migrations were kindly determined by Dr W. R. Bergren) The chromatographic behaviours on 'Amberlite *IRC*-50' are detectably, but very slightly, different[11]. Whether the above are the sole differences in composition is, of course, to some extent uncertain because of the usual inaccuracies of amino-acid analysis; for this reason, one cannot be sure that the serine content of the α-chains is different The amino-acid composition in no way can provide information about changes in sequence without changes in composition

While these restrictions must be kept in mind, the α-chains of gorilla and human hæmoglobin may well differ by only two residues and the β-chains by one residue. The differences, then, appear to be of the order observed between normal and abnormal human hæmoglobins Indeed, abnormal human hæmoglobins such as hæmoglobin *S* or hæmoglobin *I* differ from normal human hæmoglobin apparently only by one amino-acid substitution in one or the other chain[12,13] One might say that the β-chain especially has the characteristics of an abnormal human β-chain although a human β-chain corresponding to the gorilla β-chain has not yet been found. The results suggest that the hæmoglobin genes of man and gorilla constitute a single population

We wish to express our appreciation of valuable discussions with Prof Linus Pauling. Mrs Joan Balog Shelton and Mr Johnson Cua have given competent technical assistance.

IMMUNOLOGY

A 'Microspot' Test for Antigens and Antibodies

The immunologist is often confronted with the problem of determining the presence of low concentrations of antigens in solution, or of establishing the antigenic specificity of a substance available only in minute quantities On the contrary, he is also frequently concerned with the conservation of small quantities of hard-won antisera One answer to both these problems is a technique worked out in these Laboratories

The principle of the technique encompasses the coating of microscope cover-glasses with a thin layer of antiserum-agar, on which microspots of the solutions of the antigens are deposited from fine capillary tubes The cover-glasses are kept in a moist atmosphere for a suitable period of time and then examined for the presence of spots of antigen-antibody precipitate at the sites of antigen application In a strong antigen–antibody system precipitation spots will be visible in 1–2 hr After 24 hr most positive reactions will be detectable; but it is advisable to keep the cover-glasses for 3 days for the possible appearance of further very weak reactions.

Reading of the moist preparation will generally suffice, and photographs may be made for record In addition, the preparations may be soaked for periods successively in saline and distilled water and dried at 37° C The agar film adheres firmly to the cover-glass and a permanent mount is produced At this stage viewing the surface of the agar by reflected light against a black background may reveal faint spots not apparent in the moist state The precipitation spots on the dried preparation are readily stained with a suitable dye, such as ponceau *S*, with virtually no background staining Such stained preparations can be mounted between lantern-slide cover-glasses for projection

In practice, we have used 5–15 per cent serum-agar for the coating of the cover-glasses, that is, 0·025–0·075 ml antiserum plus 0·475–0 425 ml

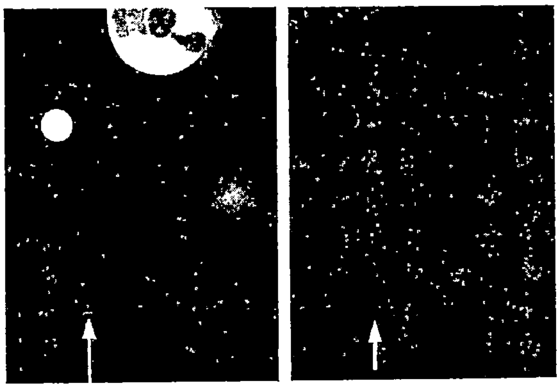

Fig 1 Comparison of microsp detection of duck ovalbumin in wet preparation (left) and after drying and staining (right) Antigen concentrations, from top 10,000, 1,000, 100, 10 μgm /ml 1 per cent specific antiserum in agar gel (× c 3 5)

1 per cent agar respectively, mixing the two at about 57° C It is advantageous to use specially purified agar[1] One-half ml of agar will readily coat 5–6 one-in circular cover-glasses, which may be stored in a moist atmosphere until required No 3 thickness cover-glasses are preferred for their lower fragility

The amount of antigen which can be detected depends on the antigen–antibody system involved We have succeeded in detecting as little as 10 μgm / ml of duck ovalbumin and the γ-globulin in a 1 100 dilution of human serum We have not yet determined the minimum amount of antibody required in the antiserum to produce a positive test

We have already applied the technique to the detection of antigen in eluate fractions from chromatographic columns This, together with the detailed methodology of the technique and alternative use of serum-impregnated papers and membranes, will be reported elsewhere

I am indebted to Alan W Wheeler for technical assistance and to Douglas F Lawson for the photographic recordings

Acrolein and Mengo-Semliki Virus Immunity

A PREVIOUS report[1] and unpublished qualitative immunochemical findings indicated that acrolein combines with various serum proteins without altering species characteristics During this work the antiseptic qualities of acrolein were evident by the absence of growth of microscopic organisms, no growth was demonstrable at any time in any of the sealed acroleinized preparations that had been stored at room temperature during a ten-year period This is of special interest since strict sterile precautions were not exercised during collection of any of the animal sera These observations, and the known toxic effects of acrolein, suggested application in the preparation of vaccines

This initial report concerns animal experimental work with acroleinized Mengo and Semliki viruses Mengo and Semliki Forest viruses were chosen for this initial acute experiment because of their known lethal virulence for mice Paralysis and death following infection occur in unprotected mice over a period of 1–8 days, depending on the age of the mice, route of administration and the number of lethal doses of live virus injected

Stock virus was obtained from the Department of Clinical Virology, Sloan-Kettering Institute Mengo virus stock 4, dated November 10, 1958 (unknown number of brain passages), stored frozen as 20 per cent mouse brain supernatant with 5 per cent human serum-saline, intracranial titre, 10^{-8} in 5–6-week-old mice, Semliki Forest virus stock 4, dated December 3, 1959 (8th brain passage), stored frozen as 20 per cent mouse brain supernatant in 5 per cent mouse serum-saline, intracranial titre, 10^{-7} in 5–6-week-old mice Swiss Webster mice, approximately 5 weeks old, weight 16–18 gm , were used Acrolein (bulk acrolein stabilized with hydroquinone, maximum hydroquinone 0 1–0 2 per cent, supplied by Dr T J Hall, Union Carbide Chemical Co , New York, N Y) 0 2 per cent in 0 85 per cent chilled sterile saline was freshly distilled and used immediately in each experiment

Stock Mengo virus (20 per cent) was diluted tenfold with sterile distilled water to 2×10^{-3} Stock Semliki virus (20 per cent) was diluted tenfold to 2×10^{-2} This was injected intracranially in two groups of mice in 0 3-ml doses per mouse Brains from only the living moribund as well as the clinically well Mengo- and Semliki-infected mice were collected rapidly and aseptically and pooled approximately 24 hr and 44 hr respectively following injection This was not titred The brain tissue was immediately macerated with scissors and homogenized in a 'Tri-*R* Teflon tissue homogenizer with a small quantity of 0 2 per cent acrolein necessary to maintain a liquid state Following homogenization, sufficient chilled 0 2 per cent acrolein was added to make a final 20 per cent brain suspension The suspensions were put in brown sterile rubber-stoppered vaccine bottles, exposed to room temperature for 24 hr and stored in a refrigerator at 1–5° C As control for the detection of live virus, Mengo and Semliki vaccines 12 days and 28 hr respectively after preparation were serially diluted tenfold with sterile distilled water and injected intracerebrally in 0 03-ml doses in groups of mice approximately five weeks old There was no evidence of illness or death over an observation period of 15 days, at which time the animals were killed

In a similar test experiment, live stock Mengo virus, diluted 1 10 with 0 2 per cent acrolein was shown to be inactivated after exposure for 30 min at room temperature (Incidentally, 0 2 per cent acrolein inactivates Rous sarcoma, Friend's leukæmia and Egypt 101 viruses after 24 hr exposure at room temperature) Tissue cultures for the detection of live virus were not carried out

For immunization tests, mice of the same delivery tag-date age were divided into three separate groups One group was vaccinated with Mengo vaccine (age 3 days) subcutaneously, one group peritoneally, and the third group was unvaccinated to be used as controls Vaccination consisted of a 0 1-ml injection of acroleinized 20 per cent suspension of mouse brain initially, repeated every seven days for a total of four injections Ten days following the last injection, the vaccinated and unvaccinated controls were challenged intraperitoneally with live stock Mengo virus With the Semliki vaccine (age, 1 day), mice of the same tag-date age were divided into four groups Two groups were vaccinated intraperitoneally, receiving 0 1 ml of vaccine initially, repeated every seven days for a

* No deaths over a 15-day period of observation

Intraperitoneal (*IP*), intracranial (*IC*) route of administration of live virus

total of four injections. Two groups remained unvaccinated for use as controls. Ten days following the last injection, the four groups were challenged with live stock Semliki Forest virus.

Results are summarized in Table 1. (1) The group vaccinated intraperitoneally was protected against approximately one million (LD_{50}) lethal doses of live Mengo virus, while the group vaccinated subcutaneously showed only irregular partial protection. (2) The vaccinated group challenged intracerebrally was protected against approximately 2 000 (LD_{50}) lethal doses of Semliki Forest virus. It is interesting to note that three mice from each of these groups received undiluted 20 per cent stock virus (2×10^{-1}). The results of challenge via the intraperitoneal route in the other two groups shows a one log protection in the vaccinated mice.

Space does not permit a detailed discussion; however, it appears that acrolein stabilizes without altering the basic compound molecular pattern of the viruses studied. While the molecular configuration was probably altered to some extent by acrolein, there was no noticeable loss in the capacity of the acroleinized virus to act as an antigen when injected into mice. The immune response was determined by the ability of the vaccinated mice to survive challenge against overwhelming lethal doses of live virus injected, and not by the test-tube type determination, based on the amount of reactive humoral substances present in serum.

I am indebted to Dr. Emerson Day for his co-operation and help in initiating this work and to Dr. Chester Southam for his criticism and giving me facilities for this investigation.

PATHOLOGY

Absorption and Excretion of Penicillin injected into the Muscles of Patients with Diabetes Mellitus

THE observation that two patients with sub-acute bacterial endocarditis due to alpha-streptococci highly sensitive to penicillin *in vitro* failed to respond to administration of six million units of the drug a day led to investigations which revealed low peak blood-levels and abnormal urinary excretion of the antibiotic in both. When the dose of penicillin was increased to a quantity greatly in excess of that suggested by the test-tube sensitivity of the organisms, favourable clinical response followed promptly. Other than the endocarditis, the only finding common to both individuals was the presence of diabetes mellitus. Since a review of published information concerning the pharmacology of penicillin[1-4] revealed no data indicating any abnormalities related to the diabetic state, it was decided to investigate this problem.

Two types of subject were investigated: (*a*) patients with established diabetes mellitus controlled by diet alone or with insulin, (*b*) individuals with no clinical or laboratory evidence of diabetes who were approximately the same age as the diabetics. They were selected on this basis in order to eliminate, so far as possible, the effect of age on the efficiency of renal tubular excretion of penicillin. A single dose of 10,000 units (6 mgm.) of crystalline benzyl penicillin *G* per kgm. of body-weight was injected into the gluteus. Blood and urine specimens were obtained before treatment and 1/2, 1, 2, 4, 6, 8, 24, and 48 hr. after antibiotic administration. Concentration of penicillin in the blood was determined by the tube-dilution and agar-cup methods. The quantity of drug in the urine was estimated by the tube-dilution technique. The test organism used was *Staph. aureus* (var. *pyogenes*) *FDA* 209*P*.

Thirty-one diabetic subjects and twenty-nine normal 'controls' were investigated. There was some variation in the rates of absorption and excretion of penicillin, some individuals with diabetes being indistinguishable in this regard from those without this disease. However, as illustrated in Fig. 1, calculated averages revealed striking differences. Peak blood-levels were reached earlier (1 hr.) and were higher (8 units/ml.) in the controls than in the diabetic patients (2 hr. and 5·4 units/ml. respectively). Disappearance of penicillin from the serum appeared

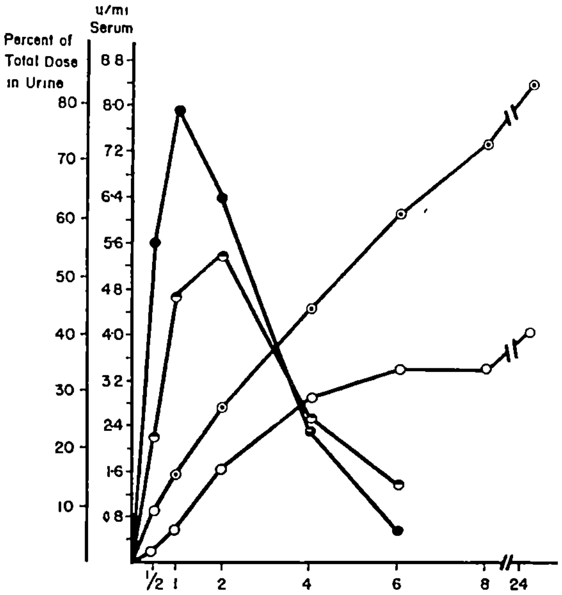

Fig. 1. Serum penicillin content determined by cup-plate assay and cumulative urinary excretion assayed by a two-fold serial dilution method. ● Penicillin-level in serum non-diabetic, ⊙, non-diabetic urine concentration. ⊖, serum-level in diabetic, O, diabetic urine concentration

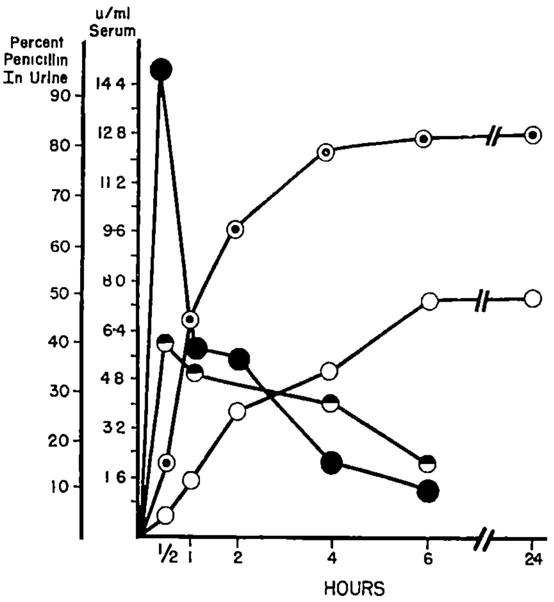

Fig 2 Penicillin content of serum and urine in one diabetic subject after both intravenous and intramuscular administration ○, Cumulative penicillin excretion in urine of diabetic after intravenous dose 10,000 units/kgm , ○, penicillin excretion after intramuscular dose of 10,000 units/kgm , ●, serum content after intravenous dose, ◓, serum content after intramuscular dose

to proceed at the same rate in both groups The half-life of the antibiotic was found to be almost identical, 0 79 hr in the non-diabetics and 0 83 hr in those with diabetes

The urinary excretion of penicillin by diabetic patients, although somewhat variable, was, on the average, very different from that of the controls (Fig 1) The normal subjects cleared approximately 50 per cent of the injected dose of drug via the kidney in 2 hr , 80 per cent after 8 hr , and 95 per cent after 24–48 hr The average urine output of antibiotic in diabetics was found to be only 25 per cent after 2 hr and 50 per cent after 24 hr Specimens of urine obtained from both groups after 36 hr contained too little penicillin to be detected by the method used, since concentrations less than 10 units/ml. were not measured

Since the data obtained indicated that the absorption and excretion of penicillin were abnormal in diabetes mellitus, investigations were carried out to determine the responsible mechanism. The possibility that variation in degree of protein-binding of the antimicrobial agent might be involved was eliminated by failure to demonstrate significant changes in antimicrobial activity when penicillin, in varying quantities, was incubated *in vitro* with serum, plasma, whole blood, and urine of diabetic and normal subjects The fact that the half-life of the antibiotic was found to be essentially the same in both groups suggested that (*a*) derangements in kidney function associated with the diabetic state, (*b*) destruction of the drug, or (*c*) a metabolic pathway other than that available in normal individuals was probably not responsible for the reduced serum-levels and renal clearance in diabetes An investigation was undertaken, therefore, to determine the role of the site of injection of penicillin on its absorption and excretion in normal and diabetic patients

One patient with diabetes mellitus controlled by diet and insulin has thus far been investigated. He was first given the standard dose of penicillin intramuscularly and blood and urine concentrations were determined 1/2, 1, 2, 4, 6, and 24 hr after treatment Concentrations of drug in the blood were determined using the agar-cup method and in the urine by the tube-dilution technique Several days later, he was given the same dose of penicillin intravenously and blood and urine collected at the same intervals The results of this work are presented in Fig 2 The curves of serum and urine concentrations when penicillin was given intramuscularly approximate closely those presented in Fig 1 as an average for thirty-one diabetic subjects Quite distinct are the blood-levels and cumulative urinary excretion following intravenous administration of the antibiotic, these resemble closely those presented in Fig 1 as average for twenty-nine 'controls' The total quantity of penicillin excreted in the urine was considerably larger when it was given intravenously than when it was injected into a muscle These results suggest that the low peak blood-levels and decreased urinary excretion of antibiotic noted in patients with diabetes mellitus are probably due to defective absorption from an intramuscular depot and not to altered renal function, increased rapidity of destruction, excessive protein binding, or metabolism via an unusual pathway

The observations which have been presented appear to be significant not only because they indicate that absorption of penicillin from intramuscular sites is abnormal in diabetes mellitus, but also because they suggest the possibility that other substances may also be absorbed relatively poorly and that this represents a basic absorptive defect in this disease

This work was carried out under a grant from Lilly Laboratories, Indianapolis, Indiana

Establishment of Amœbic Hepatitis as a Distinct Clinico-Pathological Entity

THERE is much controversy as to whether or not amœbic hepatitis occurs as an entity, as distinct from the well-recognized amœbic liver abscess Recently, we reported a case of long-standing amœbiasis with hepatomegaly which, on liver biopsy, showed histologically the presence of cells morphologically similar to amœbæ, diffusely infiltrating the liver without abscess formation[1]

Further support to our concept of amœbic hepatitis is given by two patients on whom we now report These patients, both with amœbiasis and hepatomegaly without liver abscess, were found to have cells, morphologically similar to amœbæ, diffusely infiltrating the liver on biopsy examination

On laparotomy, the liver of both patients had a fine granular appearance and histologically showed inflammatory infiltration and some portal fibrosis Liver tissue from the biopsies was injected into the liver of hamsters, guinea pigs and rabbits In the hamsters and the rabbits, liver abscesses were produced which showed the presence of cells morphologically similar to amœbæ, such cells had also diffusely infiltrated the liver

The passage of the disease from the human to the experimental animals, we believe, gives further support to the view that diffuse amœbic hepatitis exists as a distinct clinico-pathological entity

ANATOMY

Third Molar Polymorphism and the Timing of Tooth Formation

AGENESIS (congenital absence) of the third molar tooth is a familiar polymorphism in man, with a population frequency of at least 9 per cent in Europeans[1]. Hitherto, congenital absence of this tooth has been considered as an independent trait, or at most associated with reduction in size when agenesis is incomplete However, there is evidence connecting the presence or absence of the third molar tooth with the timing of formation of the premolar and molar teeth as well

In a series of 172 white children born in Ohio (excluding monozygotic pairs), agenesis of the lower left third molar was radiographically confirmed in 22 subjects aged fourteen years or older The time of formation of the remaining lower left premolar and molar teeth was determined from serial, longitudinal oblique-jaw radiographs[2] and expressed as sex-specific normalized T-scores[3] so that data on boys and girls could be combined As shown in Table 1, children lacking the mandibular left third molar were consistently later in premolar and molar tooth formation than 126 'controls' from unaffected sibships

Table 1 CALCIFICATION TIMING OF THE POSTERIOR TEETH IN CHILDREN LACKING $\overline{M}_3$, THEIR SIBLINGS, AND IN CHILDREN FROM UNAFFECTED SIBSHIPS

	Calcification timing									
	$\overline{P}_1$		$\overline{P}_2$		$\overline{M}_1$		$\overline{M}_2$		$\overline{M}_3$	
Group	N	T*	N	T*	N	T*	N	T*	N	T*
Affected children	21	53	20	54	18	52	21	59	—	—
Siblings of above	22	56	20	53	17	52	24	52	24	57
Unaffected children	111	48	118	49	81	48	126	48	125	49

* Normalized sex-specific T-scores (ref 3) for beginning tooth formation, primarily beginning cusp calcification (ref 4)

Furthermore, 24 unaffected siblings of children with third molar agenesis were compared with the unaffected children from unaffected sibships These unaffected siblings of the propositi also proved late in tooth formation, especially for mandibular third molar formation which averaged 8 T-scores behind the controls (Table 1) For all 150 unaffected children, earliness or lateness of $\overline{M}_3$ formation was significantly associated with the type of sibship from which they came ($\chi^2 = 6 4$) Thus, the tendency for delayed tooth formation when the third molar is missing is characteristic of affected lineages and not restricted to affected individuals alone

Since absence of the mandibular third molar was associated with delayed formation of the molar teeth, it was not surprising to find differences in the sequence of tooth formation[5] between the 22 children with third molar agenesis and the 126 normal controls Thus, 60 per cent of children in the present work who lacked the mandibular third molar were of the P_2M_2 sequence of cusp calcification, while this sequence or order was far less common (22 per cent) in the 126 controls Third molar polymorphism was unquestionably associated with the P_2M_2/M_2P_2 sequence polymorphism ($\chi^2 = 25 01$)

Third molar agenesis, therefore, may be viewed as the extreme degree of expression of factors delaying tooth formation over a long developmental period ranging from the first month of life (for M_1) to the eighth year or beyond (for M_3) Moreover, this common polymorphism is related to the previously described familial P_2M_2/M_2P_2 calcification sequence polymorphism[6], indicating a common determinant for the two

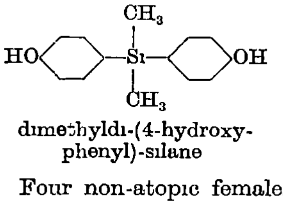
HISTOCHEMISTRY

Allergy to a Carbon-Functional Organic Silicon Compound, Dimethyldi-(4-hydroxyphenyl)-silane

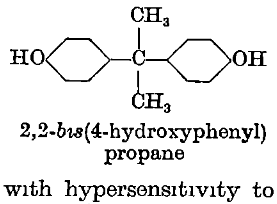
THE noxious effects of certain inorganic silicon compounds are well known[1] Polymeric organic silicon compounds, on the contrary, are chemically very inert and show a low toxicity[2] Some organic silicon compounds may, however, produce toxic effects[3]

Inorganic or organic silicon compounds—the latter not present in Nature[4]—are so far not known as allergens

As a close relationship exists between silicon and carbon atoms, it was assumed that cross-sensitization could occur between silicon and carbon compounds Therefore the allergenic nature of dimethyldi-(4-hydroxyphenyl)-silane[5] was investigated since the carbon compound, 2,2-*bis*(4-hydroxyphenyl)propane ('Bisphenol *A*'), has been demonstrated as an allergen[6]



dimethyldi-(4-hydroxyphenyl)-silane



2,2-*bis*(4-hydroxyphenyl) propane

Four non-atopic females with hypersensitivity to 2,2-*bis*(4-hydroxyphenyl)propane, demonstrated by positive patch test (1/100 dilution in ethyl alcohol), showed positive reactions to dimethyldi-(4-hydroxyphenyl)-silane (1/100 dilution in acetone) The positive tests were characterized by the presence of erythema, infiltration and papules/vesicles

This is the first report on allergy to an organic silicon compound Absence of earlier contact with the silane is evidence of cross-sensitization.

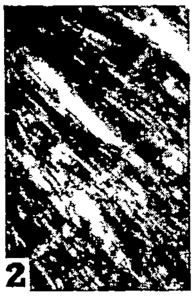
Use of Tetrazolium Compounds in Oxidative Enzyme Histo- and Cyto-Chemistry

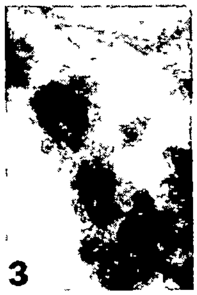
A NEW tetrazolium salt previously synthesized has been evaluated for its ability to overcome the technical and theoretical barriers of either the MTT-Co (ref 1) or nitro-BT methods[2,3] This compound is TNBT or 2,2′,5-5′-tetra-*p*-nitrophenyl-3,3′-(3,3′-dimethoxy-4,4′-biphenylene)-ditetrazolium chloride (Fig 1), the formazan of which is purplish black[4] The TNBT used in the following investigations produced a brownish-black precipitate in tissue sections Though quite low in water solubility, minimal concentrations of TNBT are required for the effective demonstration of the succinic dehydrogenase system in fresh, frozen sections of tissue of mammalian tissues or human vaginal smear preparations The following were investigated in mouse myocardium and kidney (1) effect of concentration of dye on the products of TNBT formazan in slices of these tissues; (2) effect of *p*H on the reduction of TNBT by the succinic dehydrogenase system in tissue sections in the presence or absence of appropriate substrate, (3) solubility of TNBT formazan in aqueous, alcoholic and other organic solvents necessary for the effective resin-mounting of sections of tissue containing precipitates of formazan.

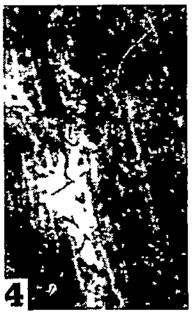
Results indicate that

(1) Varying the concentration of TNBT in the incubating medium from 0·001 mgm /ml to 1·25 mgm /ml through the use of an appropriate solvent has considerable effect on activity of the succinic dehydrogenase system in sections of heart and kidney. The best concentrations of this tetrazolium appear to be in the range 1 25 mgm /ml –0 25 mgm /ml. (Figs 2 and 3)

(2) Maximal deposition of TNBT formazan occurs in succinic dehydrogenase-stained tissue sections over a wide range of *p*H. Tissues incubated in TNBT solutions containing succinate and phosphate buffer with *p*H values of 6 8–8 4 show heavy staining reactions with little variation in intensity as a result of the concentration of hydrogen ions In the absence of succinate, extremely pale non-granular tints appeared in the tissue sections, especially at *p*H 8 4 The very faint staining, when visible in such specimens, was distinctly different from the TNBT formazan granulations seen in localizations of the succinic-dehydrogenase system







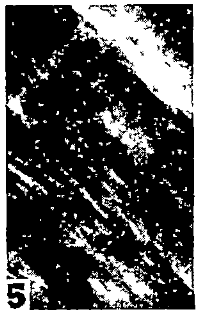


Fig 2 Mouse myocardium stained for the succinic dehydrogenase system using TNBT The muscle cells are well stained and cross-striations are evident in many regions of the myofibrils Note the absence of staining in nuclei and intercalated disks (upper right, lower left, centre) 5-μ section (× 300)

Fig 3 Mouse kidney stained for succinic dehydrogenase system using TNBT Heavy deposition of the diformazan is seen in the proximal tubules while no staining is apparent in the glomerulus (left) Note faint staining of smooth muscle in the tunica media of the artery (top) 10-μ section (× 60)

Fig 4. Mouse myocardium stained for the succinic dehydrogenase system nitro-BT Coarse granular precipitate marks the site of enzyme while occasional crystals can be seen (middle) in extracellular regions 5-μ section (× 600)

Fig 5 Mouse myocardium stained for the succinic dehydrogenase system using TNBT The fineness of the diformazan precipitate sharply delineates the mitochondria within the muscle cells In addition, note the clearly defined inactive nucleus (centre) under which is situated a portion of a stained myofibril Unstained intercalated disk (upper left) 5-μ section (× 600)

(3) TNBT formazan, enzymatically produced in tissue sections or in non-enzymatic systems using dithionite, is as insoluble as nitro-BT formazan in any of the ordinary organic solvents used in the resin-mounting of tissue sections.

(4) Crystallization phenomena such as those observed in nitro-BT formazan specimens (Fig 4) have never occurred in TNBT-stained tissue sections (Fig. 5).

(5) The granular precipitate of TNBT formazan can be of such a fine dimension, suggesting a more correct staining picture rather than that of an

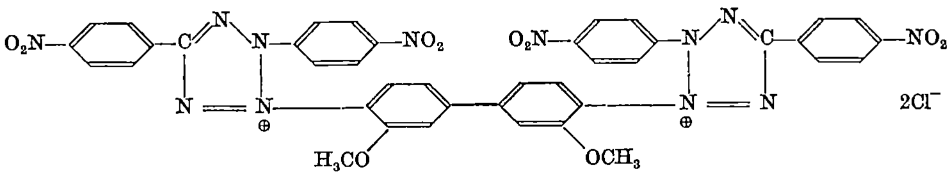

Fig. 1. Structural formula of 2,2′,5,5′-tetra-*p*-nitrophenyl-3,3′-(3,3′-dimethoxy-4,4′-biphenylene)-ditetrazolium chloride (TNBT)

accumulated precipitate over intracellular organelles This localization is under investigation at present using electron histochemical techniques similar to the procedures of Sedar and Rosa[5]

(6) Cyanide inclusion into incubating media shows little effect in highly active tissues such as heart and kidney Its use for enhancement of staining in tissues of the female reproductive tract appears to be warranted, especially in regions where low succinic dehydrogenase activity prevails

In conclusion, TNBT appears to possess qualities suitable for the histo- and cyto-chemical localization of oxidative enzymes in tissue sections of mouse heart and kidney These properties strongly suggest that TNBT may be a more efficient reagent for the cytochemical demonstration of enzyme systems such as succinic dehydrogenase and diphosphopyridine nucleotide diaphorase

BIOLOGY

Anaerobiosis and Sodium Accumulation

Accumulation of most cations by higher plants is considered to be an aerobic process However, we now find that sodium is in part an exception to this generalization. Uptake of sodium by 6-day old plants of *Hordeum vulgare*, variety Atlas 46, occurs under both aerobic and anaerobic conditions Accumulation in the roots under anaerobic conditions is restricted to a period of about 2 hr (Fig 1), during which time transport to the shoots is almost nil (Fig. 2) The amount of sodium accumulated by plants the roots of which are in either aerobic or anaerobic solutions is inhibited by substances such as iodoacetate and methylene blue, indicative of the initial uptake being coupled to metabolic reactions in both cases rather than to passive processes Non-steady-state uptake by the anaerobic plants, which decreases with time as if some process is attenuating, suggests that the reactions involving sodium uptake are several steps removed from the respiratory chain.

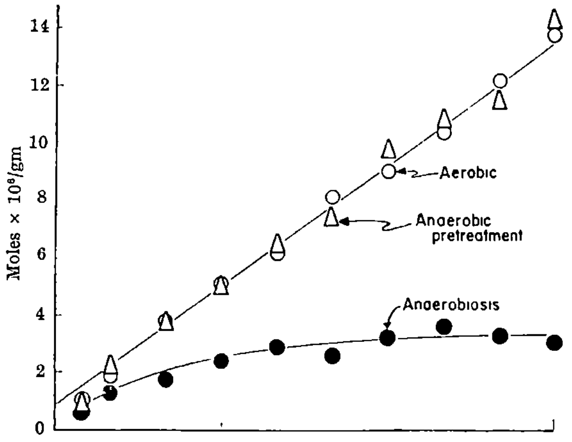

Fig 1 Accumulation of sodium ions by roots from a 10^{-3} *M* solution at *p*H 5 0

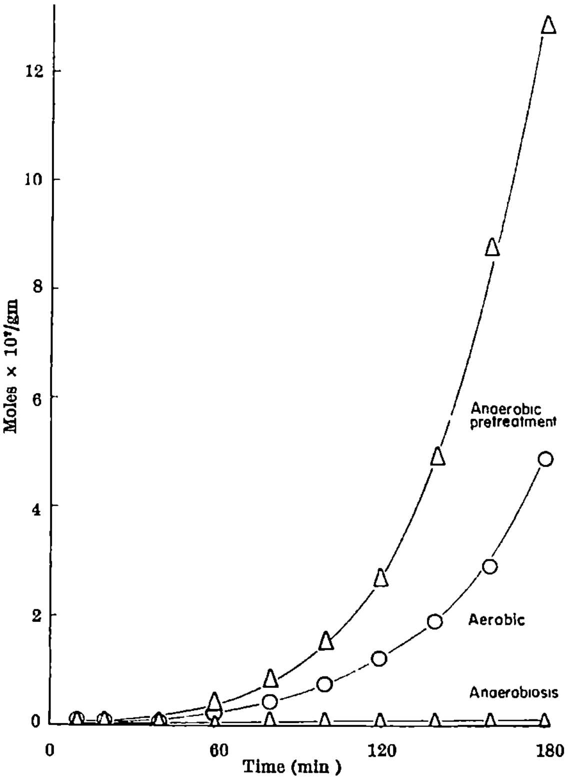

Fig 2 Transport of sodium ions to the shoots from 10^{-3} *M* solution at *p*H 5 0

Previously observed accumulation of sodium in plants under anaerobic conditions[1–3] over long periods of time was often considered in discussion as possible passive entry due to plant damage That the plants are not damaged by anaerobiosis in the present experiments is indicated by return to normal respiration after 60 min of anoxia and 15 further hours under aerobic conditions At the end of this treatment the rate of sodium accumulation in the shoots is increased but can be stopped by returning the plants to an anaerobic situation or by the use of inhibitors Anaerobiosis *per se* does not activate sodium uptake ; rather it increases the rate of sodium uptake on returning to aerobic conditions.

Activation of sodium uptake by shoots produced by anaerobic pretreatment of roots, either by bubbling nitrogen or carbon monoxide gas through the solution, occurs chiefly from the higher sodium concentrations (> 10^{-4} *M*). Two or more reactions appear to be involved in the uptake of sodium by roots[4] and shoots. The activation of anaerobic pretreatment is on the reaction for shoot accumulation which dominates at the higher sodium concentrations

The uptake of potassium and phosphate differs from sodium accumulation in respect to anaerobiosis

Both potassium and phosphate accumulation are immediately suppressed by anaerobic conditions and return only to the normal value in air (no enhancement). Accumulation was followed in all cases by the amount of radioisotopes appearing in the roots or tops.

Effect of Environment on the Responses of Dwarf Groundsel to Gibberellic Acid

THE striking effects of gibberellic acid on internodal elongation in dwarf mutants and rosette plants of a number of species are now well established, and the effects of this substance on a single gene dwarf mutant, induced by γ-radiation in groundsel, *Senecio vulgaris* L., have recently been described[1]. The observations now reported show that the responses of this mutant to gibberellic acid may be considerably affected, both quantitatively and qualitatively, by environmental conditions. In fact, the phenotypic expression of both wild-type and mutant groundsel is greatly influenced by the environment: in certain unfavourable conditions the plants are stunted and the vegetative phase is prolonged. When the wild-type (tall) and mutant (dwarf) groundsel are grown in a greenhouse during the normal growing season, that is, from early spring to late summer, the transformation of the vegetative apex to an inflorescence apex occurs not later than 2 weeks after the emergence of seedlings from the soil, and fruiting begins when plants are 7–10 weeks old; but the apices of tall and dwarf plants grown in a growth cabinet under 'daylight' fluorescent tubes, 400 foot-candles, with a day-length of 10 hr., and a temperature of 22 ± 2° C., remained vegetative for 11 weeks.

Dwarf groundsel has shorter and fewer internodes than the wild-type plants of the strain from which it was derived. Mitotic activity is significantly less in the apical meristem and subapical region of the shoot in dwarfs than in wild-type plants. Treatment with gibberellic acid of dwarfs grown in a greenhouse leads to a conspicuous and precocious extension of the internodes due to enhanced mitotic activity and cell elongation in the subapical region of the shoot[1]. No evidence of any response of the tissues of the apical meristem was obtained, and there was no significant increase in the number of nodes.

Both tall and dwarf genotypes in the growth cabinet grew poorly and remained stunted. In these conditions, however, the genetic dwarfs responded proportionately more strongly to gibberellic acid than when they were grown in the greenhouse. Treated mutants were taller than untreated tall plants of the same age in the same environment, although they were not even as tall as untreated dwarfs grown in the greenhouse. An increase in the number of leaves, and thus of internodes, on the main axis of treated dwarfs in the growth cabinet was also observed (Table 1), and since leaf primordia originate on the apex, such an increase must reflect the influence of gibberellic acid on the apical meristem.

Table 1. EFFECT OF ENVIRONMENT ON THE HEIGHT AND NUMBER OF INTERNODES OF TALL AND DWARF GROUNDSEL AND THOSE TREATED WITH GIBBERELLIC ACID (GA)

Tall, control	40·4 (1·05)	2·2 (0·27)	14·2 (0·46)	15·5 (2·40)
Tall, GA-treated	45·2 (1·05)	8·0 (3·44)	13·8 (0·58)	17·6 (0·70)
Dwarf control	8·6 (1·01)	0·6 (0·16)	7·9 (0·16)	10·8 (1·27)
Dwarf, GA-treated	39·1 (1·52)	5·9 (2·53)	8·5 (0·63)	16·6 (1·56)

95 per cent confidence interval given in parentheses.

Exp. *A*, greenhouse. 18 plants in each group, measured at 47 days old when all plants were fruiting. Treated plants received 10 p.p.m. gibberellic acid at weekly intervals (6 treatments).

Exp. *B*, growth cabinet. 6 plants in each group, measured at 77 days old; most plants were still vegetative at the time of the final measurement, but appeared unlikely to survive to complete the life-cycle. Treated plants received 10 p.p.m. gibberellic acid twice weekly for the first three weeks, and once a week thereafter (13 treatments).

In order to obtain apical material from plants in the growth cabinet comparable with 8-day-old seedlings from the greenhouse, 20-day-old seedlings had to be selected, because of the slower growth and prolonged vegetative phase of plants in the growth cabinet. Observations of longitudinal sections of shoots from the growth cabinet which had been treated with 10 p.p.m. gibberellic acid twice weekly (6 treatments), showed that while the most striking morphogenetic effect of gibberellic acid was again on the sub-apical tissue of treated dwarfs, there was also a significant ($P = 0·05$) effect on the apical meristem. Treatment with gibberellic acid of dwarfs grown in these special conditions enhances cell division in the apical meristem and brings it to the level observed in normal tall plants grown in the same environment (Table 2). Since there were fewer than 10 mitotic figures in the apical and subapical regions of most shoots, tests of significance were carried out on data transformed by the method $\sqrt{X + 0·5}$, where X is the number observed[2]. As already stated, when groundsel seedlings were grown in greenhouse conditions where the vegetative phase is of relatively brief duration, no indication of any morphogenetic response of the apical meristem to gibberellic acid was obtained, and this is in accord with observations on other species[3,4]. When, however, groundsel seedlings were grown in an environment in which the initiation of the reproductive phase was delayed, permitting a longer period of gibberellic acid treatment while the apex was vegetative, there was clear evidence of a response of the apical meristem.

It may well be that stem elongation in normal and dwarf groundsel is modified by two major factors, namely, photosynthesis, which provides the basic substrates for growth, and gibberellin, which regulates the distribution of growth, and to the extent that the latter determines what proportion of the

Table 2. MEAN NUMBER OF MITOSES IN A MEDIAN PANEL 36μ IN THICKNESS (6 MEDIAN LONGITUDINAL SECTIONS, 6μ PER SECTION) OF SHOOT TIPS IN GROUNDSEL

Type of plant	Mean number of mitoses: Apical meristem Exp. *A*	Apical meristem Exp. *B*	Subapical region Exp. *A*	Subapical region Exp. *B*
Tall (wild-type) plant	6·0	3·8	4·6	3·0
Untreated dwarf	3·2	2·0	1·0	1·3
GA-treated dwarf	3·2	3·6	6·4	6·4

Exp. *A*. Greenhouse. 5 plants, 8 days old, treated with 10 p.p.m. gibberellic acid on alternate days (4 treatments).

Exp. *B*, Growth cabinet. 10 plants, 20 days old, treated with 10 p.p.m. gibberellic acid twice weekly (6 treatments).

products of photosynthesis is incorporated in leaf tissue, changes in it lead to changes in the former.

It seems likely that the heights of dwarf and normal plants grown in the greenhouse were limited, though to markedly different degrees, by deficiency of endogenous gibberellin, since both types of plant responded to applied gibberellic acid, the former strongly, and the latter relatively slightly. The growth of dwarf plants was also limited by the relatively deficient photosynthesis, since the number and size of leaves are characteristically less in dwarfs than in normal plants. Photosynthetic tissue was increased in greenhouse-grown dwarfs by gibberellic acid treatment, due to an increase in the size, but not in the number of leaves. (Photosynthetic efficiency, measured as net assimilation-rate, was similar in normal and dwarf plants, and was not affected by gibberellic acid[1].)

The growth and development of untreated and gibberellic acid-treated dwarf and normal plants grown under low light intensity in the growth cabinet was profoundly modified by reduced photosynthesis, and, in consequence, the morphogenetic response of the dwarf to gibberellic acid was modified, since during the protracted vegetative phase the apical meristem responded to gibberellic acid, and the treated dwarfs produced as many leaves as normal plants. Thus the effect of gibberellic acid on the photosynthetic tissue of the dwarf mutant was relatively greater when the plants were grown in the growth cabinet than when they were grown in the greenhouse, and this may have accounted for the relatively increased stem elongation of treated dwarfs in these conditions. Stem elongation was greater in these treated dwarfs than in untreated normal plants which were probably deficient in natural gibberellin, as indicated by the response of normal plants to treatment with gibberellic acid.

It is evident that the morphogenetic responses of *S. vulgaris* to gibberellic acid are considerably modified by environmental factors, and it seems probable that this is due to effects on both the photosynthetic capacity of the plants and their native growth substances, including gibberellin. It may well be that an investigation of the responses to gibberellic acid of dwarf mutants in other species grown in different environments would be of interest, and might lead, as in this case, to still more striking demonstrations of the effects of this substance.

Volatile Mustard Oils of *Brassica juncea* Seeds

Brassica juncea Coss. and Czern. is an important cultivated mustard species. It is said to be a native of Asia and is grown particularly in China, Japan, India, Pakistan, Nepal and eastern Europe as a vegetable and an oil-seed crop, although it has also been introduced into North America and certain West European countries as an oil-seed crop and for use in the manufacture of condiments[5]. The species is of botanical interest in that it shows marked variation in external morphology, especially leaf form[1]. Variation, too, has been reported in the type of volatile oil produced on the hydrolysis of the seed glucoside; three conditions have been described: (*a*) the production of allyl isothiocyanate only[2,4], (*b*) the production of 3-butenyl (= 'crotonyl') isothiocyanate only[4], (*c*) the production of a mixture of allyl and 3-butenyl isothiocyanates[2].

In present investigations into variation in *B. juncea* in connexion with a programme of plant breeding, 96 samples of seed were obtained from a wide range of geographical sources, and grown in England; this collection was found to include all the main varietal forms of the species previously described in the literature. The volatile mustard oils of the seeds were identified using a paper chromatographical method[3]; in this analysis two controls were run, one of allyl thiourea and the other of phenyl thiourea (which gave a reference spot from which *Rph* values of other compounds were defined). Allyl isothiocyanate gave an *Rph* value of 0.26 and the value of the only other compound detected in the test, 0.62, indicated that it was 3-butenyl isothiocyanate.

All the three conditions of volatile oil production previously described were found during these investigations, and there appears to be a correlation between this variation and the geographical distribution of the species, a situation, so far as is known, not previously reported. Seeds from China, Japan, Nepal and Eastern Europe (49 samples) exhibited only condition (*a*), with the exception of three samples which produced very faint traces of 3-butenyl isothiocyanate in addition to allyl isothiocyanate. Conditions (*b*) or (*c*) defined here were shown only by seeds from India and Pakistan (twenty-one samples). The remaining twenty-six samples received from North America and western Europe had volatile oil production entirely consistent with their described origins from various countries, namely, six samples originating from India and Pakistan showed conditions (*b*) or (*c*), and twenty samples of other origin showed condition (*a*).

The possible amphidiploid origin of *B. juncea* from *B. nigra* (L.) Koch and *B. campestris* L. may account for these variations of volatile oil production, as *B. nigra* has been reported as giving only allyl isothiocyanate[6], which has been confirmed in the present investigations, and *B. campestris* has been found to produce only 3-butenyl isothiocyanate. The correlation with geographical distribution, together with other evidence from investigations of plant and seed morphology, might suggest that natural hybridization to produce *B. juncea* has occurred at different geographical loci.

Effect of Water Movement on Salt Movement through Tomato Roots

In recent years, there has been renewed debate concerning the effect of water absorption on salt absorption through the roots of intact plants. Salt absorption is regarded by many workers as involving active transport into the xylem by a mechanism dependent on energy released in respiration[1-3]. According to this view, water movement through roots affects salt movement only indirectly by removing salt from the root xylem and thereby producing conditions favourable for increased movement of salt by active transport. On the other hand, several investigators have concluded that, in rapidly transpiring plants, salt moves into the root xylem by mass flow as well as by active transport[4-6].

Estimates of the amount of salt moved by the two processes vary widely. The methods used in the present investigation made it possible to determine accurately that fraction of the total salt moved into the root xylem which was associated with water movement. Root systems of tomato (*Lycopersicum esculentum*, variety Marglobe) started in vermiculite and grown in Hoagland's solution were used in this work.

De-topped root systems were enclosed in a pressure chamber with their stumps projecting through the lid of the chamber. The roots were immersed in aerated half-strength Hoagland's solution which, in some experiments, contained phosphorus-32 as a radioactive tracer. Water was moved through the roots by increasing the air pressure in the chamber. The rate of salt movement through the roots was determined by measuring the volume and salt concentration of the exudate collected from the stumps. Rates of salt movement by active transport were determined by measuring the salt content of root pressure exudate collected before and after pressure applications. The effect of water movement on salt movement was determined by comparing the amount of salt moved through roots when water was moved through them under pressure, with the amount moved by active transport in the absence of external pressure.

The effects of applied pressure on rates of water and salt movement are shown for phosphorus in Fig. 1 and for total salt in Fig. 2. Figs. 1*A* and 2*A* show that, as the rate of water movement through the roots increased with increasing pressure, the phosphorus and total salt concentration of the exudate decreased. The amounts of phosphorus and total salt moved through the root systems increased with increasing pressure and rate of water movement except in the pressure-range of 10–20 lb. The amounts of phosphorus and total salt in root pressure exudate, and the effects of externally applied pressure on their rates of movement, are shown in Figs. 1*B* and 2*B*. The most important effect of increased water movement under pressure was an increase in the total amount of ions moved through the roots. This is shown by the fact that the amounts of phosphorus and total salt in the exudates were always greater during pressure applications than in root-pressure exudates in the absence of pressure. At 30 lb./sq. in., the amounts of phosphorus and total salt moved through the roots were 2·0 times and 2·4 times, respectively, the amounts moved by active transport in the absence of pressure. The amounts of phosphorus and total salt moved under pressure did not increase in proportion to the increased rates of water movement

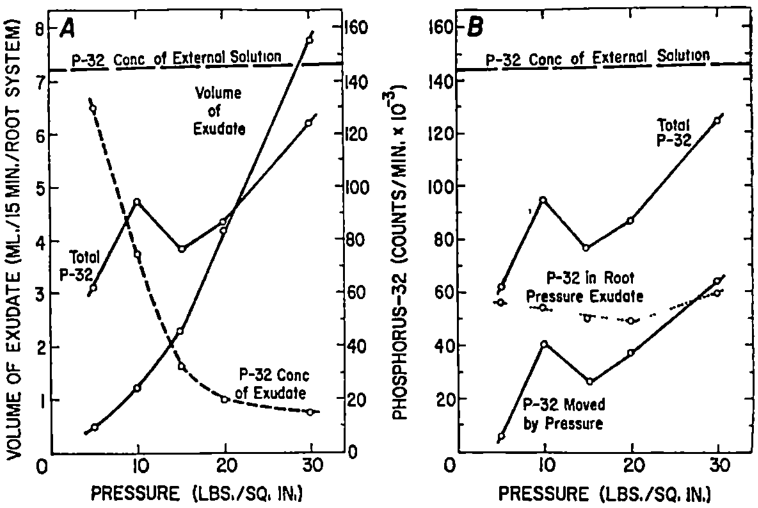

Fig. 1. *A*, Effect of pressure on rates of water and phosphorus movement through tomato roots. Phosphorus concentrations (dashed lines) are in counts/min./ml. *B*, Effect of pressure on phosphorus movement (total P-32 curve replotted from *A*). Phosphorus-32 in root-pressure exudate represents the amount of phosphorus-32 moved into the root xylem by active transport in the absence of applied pressure. Phosphorus-32 moved by pressure represents the fraction of the total phosphorus-32 which was associated with water movement under applied pressure. Points are averages of six root systems

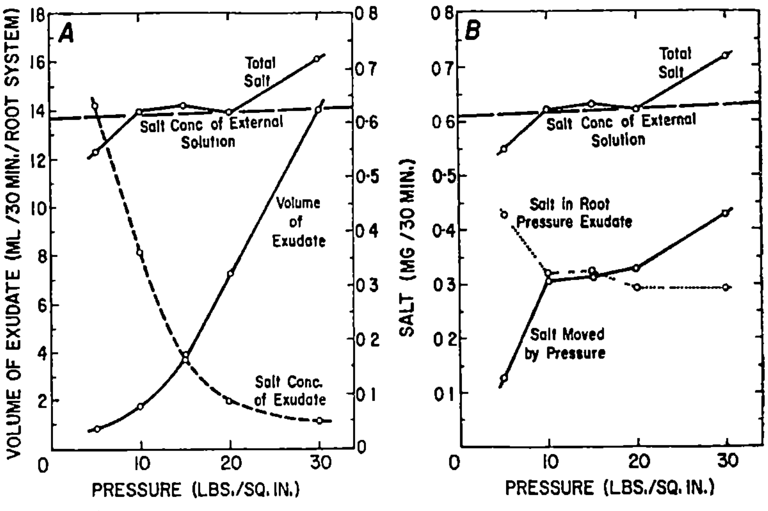

Fig. 2. *A*, Effect of pressure on rates of water and total salt movement through tomato roots. Salt concentrations (dashed lines) are in mgm./ml. *B*, Effect of pressure on total salt movement (total salt curve replotted from *A*). Salt in root-pressure exudate represents the amount of salt moved into the root xylem by active transport in the absence of applied pressure. Salt moved by pressure represents the fraction of the total salt which was associated with water movement under applied pressure. Points are averages of six root systems

Also, the salt concentration of exudates obtained under pressure usually was less than the concentration of the external solutions indicating the existence of a barrier in the roots which prevents free movement of ions into the xylem

These results show that rapid water movement through the roots greatly increases the rate of salt movement through the roots At 30 lb /sq in , more than 50 per cent of the salt moved through the roots was associated with water movement The manner in which increased water movement causes increased salt movement, however, is less certain As the rate of water movement through the roots increases, salt movement into the xylem by active transport may be accelerated by the development of a steeper salt concentration gradient across the root cells from the cortex to the xylem In addition, the change in the slopes of the total phosphorus and total salt curves at pressures of 15 and 20 lb /sq in suggests that the permeability of the roots to ions increased when higher pressures were applied Some ions might then be carried directly with water into the xylem An increase in ion permeability of root cells with an increasing pressure gradient across them was reported by Brouwer[7]

The results of these experiments indicate that at low rates of water movement salt movement is primarily by active transport However, at higher rates of water movement salt movement into the xylem probably occurs by both active transport and mass flow.

A detailed account of this work will be published elsewhere This investigation was supported by funds from the Atomic Energy Commission (Contract *AT*-(40-1)-1827)

Freeze-drying of Bovine Spermatozoa

Since 1956, increased attention has been given to techniques for freeze-drying bovine spermatozoa as a method for long-term semen preservation[1-5] In one approach[1-3], spermatozoa were dried in vacuum after being diluted, glycerolated, equilibrated and slowly frozen Low survival-rates and frequent failures were encountered Leidl[3] suggested three possible causes (*a*) concentration of glycerol to toxic levels, (*b*) excessive removal of water, (*c*) morphological damage (occasional broken mid-pieces)

In a second approach, Yushchenko[5] freeze-dried spermatozoa suspended in a mixture of 'Freon' and heptane to circumvent the harmful effects of exposure to a eutectic mixture and to eliminate mechanical damage resulting from crystallization After glycerolation and equilibration in a synthetic medium, the diluted semen was centrifuged in test-tubes containing the 'Freon'-heptane mixture The spermatozoa were thereby transferred to the non-polar medium in which they were freeze-dried With this approach he observed 15–20 per cent revival of spermatozoa

A third technique was described by Meryman and Kafig[4] in which no glycerol was used Semen diluted in heated milk or egg yolk-citrate was taken up on a 1 × 3 in sheet of nylon gauze which was suspended in a desiccating chamber connected to a high-capacity vacuum pump (27 cu ft /min) Freezing-rate was controlled by constricting the pumping orifice Since the specimen presented a high surface area to volume ratio, very rapid drying was obtained They reported 40–50 per cent spermatozoan motility following reconstitution

These three approaches have been tested in this laboratory and no set of conditions resulted in successful freeze-drying of bovine spermatozoa The earliest attempts involved diluted semen containing glycerol, occasional motile cells and many tailless sperm and broken or bent mid-pieces were observed In addition to the deleterious effects suggested by Leidl[3], semen dried in the presence of glycerol resulted in a waxy residue which could not be reconstituted readily

The procedure of Yushchenko[5] could not be duplicated in that the transfer of spermatozoa from the polar to the non-polar medium was not accomplished When the two-phase system was centrifuged, the spermatozoa were still completely enveloped by the glycerol-containing polar medium after passing into the 'Freon'–heptane mixture As expected, freeze-drying this suspension produced the characteristic waxy residue pointed out previously and also resulted in severe morphological damage Incorporation of surface-active agents such as 'Tweens', 'Carbowaxes', and lecithin did not aid the transfer of cells from the polar to the non-polar phase

In the original work of Meryman and Kafig[4] a mechanical vacuum pump with a free-air pumping speed of 27 cu ft /min was used Later, H T Meryman (personal communication, 1959) suggested that a pump of larger capacity would provide greater versatility in the present work On this basis, a mechanical pump of 130 cu ft /min capacity was used in attempts to confirm their findings Samples were frozen and dried in a 4 × 9-in glass desiccating chamber connected to the pump by a 3-in vacuum line The line was 47 in long with one 90° bend A 3-in. globe valve was inserted in the line 16 in from the desiccating chamber to control cooling-rate, ultimate temperature of the frozen specimen, and drying-rate When full pumping capacity was utilized with this system (valve wide open), diluted semen suspended on a nylon gauze could be cooled to − 50° C solely by evaporation and sublimation

More than 250 trials were made using a wide range of cooling- and drying-rates by adjusting the size of the opening in the 3-in valve Heated skim milk diluent was used in most of the trials, however, egg yolk-citrate and undiluted semen also were tested Freezing- and drying-rates comparable with those of Meryman and Kafig[4] could be achieved readily However, they did not report quantitative data on desiccating chamber pressures and residual moisture of the specimen, and failure in the present work may be due to inability to satisfy these conditions In a few trials. occasional motile spermatozoa were obtained Further investigation indicated that the motile cells usually were associated with a thickened layer of material which accumulated at the bottom of the vertically suspended nylon gauze prior to freezing. The innermost part of this material was not dry and seemed to be the source of the motile spermatozoa When the membrane was kept under vacuum

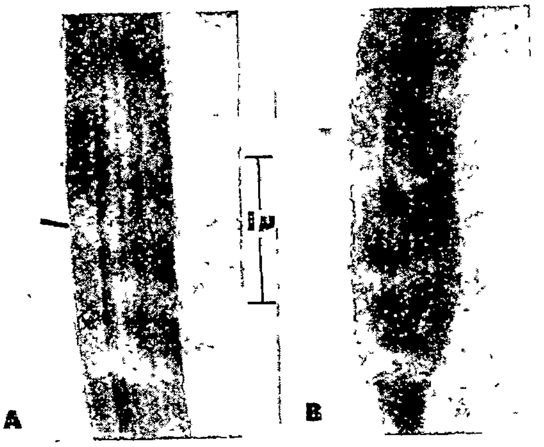

Fig. 1. Ultrastructure of the mid-piece of bull spermatozoa showing (*A*) the presence of the cytoplasmic membrane (arrow) in a control, and (*B*) its absence in a freeze-dried specimen (× *c*. 19,700)

long enough to assure complete drying of the semen, no motile spermatozoa were observed.

In contrast to cells freeze-dried in the presence of glycerol, both diluted and undiluted spermatozoa dried by the latter technique appeared morphologically normal when examined under a phase contrast microscope (× 660). Next, the ultrastructure of freeze-dried spermatozoa was studied with the electron microscope using thin sections. Freshly collected, pooled ejaculates of undiluted semen were freeze-dried on nylon mesh gauze in vacuum and reconstituted in a 2·9 per cent sodium citrate solution. Control spermatozoa were taken up on a nylon gauze and then resuspended in 2·9 per cent sodium citrate without freeze-drying or exposure to vacuum. Spermatozoa were centrifuged from the citrate solution into a loose pellet which was fixed with Caufield's modification[6] of Palade's fixative[7]. 'Araldite' was used as the embedding material and sectioning was performed with a diamond knife on a Porter–Blum ultramicrotome. Electron micrographs revealed that spermatozoa subjected to freeze-drying and reconstitution usually lacked the outer or cytoplasmic membrane (Fig. 1*B*), while control spermatozoa usually displayed an intact membrane (Fig. 1*A*). The presence or absence of the membrane was most apparent in longitudinal sections of the middle piece or principal piece. It is not known whether the same results would have been obtained if the spermatozoa had been diluted before freeze-drying. This possibility is being investigated.

The electron microscope also was used to examine undiluted spermatozoa frozen under vacuum to – 20° C. and thawed in citrate solution at room temperature and undiluted spermatozoa rapidly cooled to 0° C. by vacuum without freezing. As observed in freeze-dried spermatozoa the cytoplasmic membrane of frozen and thawed cells usually was lacking. Spermatozoa rapidly cooled under vacuum without freezing generally possessed intact membranes.

These observations on bull spermatozoa suggest that alteration or destruction of the cytoplasmic membrane represents one possible deleterious effect on survival after either freeze-drying and reconstitution, or freezing and thawing in the absence of glycerol. It is not known whether these treatments cause death and subsequent loss of the cytoplasmic membrance or vice versa. The importance of the cytoplasmic membrane and factors which affect its integrity are being investigated.

We wish to thank Dr. P. Grun and Mrs. Anne Radlow for their advice on the cytological techniques. This investigation was aided by grants from the Pennsylvania State Association of Artificial Breeding Cooperatives.

Precipitating Antibodies in the Carpet Snake against Parasitic Nematodes

To our knowledge very little attention has been paid to the formation or presence of precipitating antibodies in the cold-blooded vertebrates. Indications of active antibody formation have nevertheless been reported in frogs, turtles and fish; however these estimations were made using either agglutination or anaphylaxis[1]. This communication is a survey of naturally occurring antibodies in the carpet snake (*Morelia spilotes variegatus*) which react positively with the body fluids of their nematode parasites, *Amplicaecum robertsi*, *Ophidascaris* sp., and *Polydelphis* sp., in interfacial precipitin ring tests.

The antigen was collected by puncturing the cuticle of these nematodes and drawing the fluids up a fine glass capillary, the body fluids from approximately fifty worms being pooled, in each case, to give sufficient antigen for these experiments. Blood was collected from the aortas of twelve snakes at autopsy, defibrinated and the serum stored frozen. Table 1 shows the results of interfacial precipitin ring tests using these sera versus the body fluids of the three snake nematodes and the presence or absence of the particular infection in the snakes at the time of autopsy.

In general these results indicate that circulating, precipitating antibodies exist in the sera of carpet snakes which react with the antigens of nematodes infecting them, and that the presence of antibody is probably related to the presence of the particular infection ($P \sim 14$ per cent). Certain expected discrepancies exist in these results, namely, antibodies are present in the absence of infection and infections also occur without detectable antibody. These discrepancies can arise since we do not know either the beginning or the duration of these infections or the number of previous infections (we have noticed that carpet snakes may regurgitate their partially digested food with some of their intestinal nematodes, which may explain how some infections are lost). The possibility also exists that the circulating antibodies are non-specific. To test the specificity of these antibodies the various sera were tested against the body fluids of *Ascaris suum*, from the pig, as antigen. It was found that three of the twelve sera gave positive reactions. This apparent lack of specificity in these

three cases may be accounted for by the presence of antibodies versus Forssman antigen known to exist in certain helminths[2]. However, the carpet snake must also be able to produce specific antibodies against antigens from its three nematode parasites since the sera negative to *A suum* gave positive reactions against these worms ($P \sim 1$ per cent). Further work is being done on the natural antibodies found in the carpet snake

Fibre Follicles in Romney Ewes

ORWIN has reported[1] the occurrence of what he describes as 'branching follicles' in skin from two-year-old New Zealand Romney ewes In his communication there appears to be some confusion concerning the evidence required to demonstrate conclusively whether follicles are branched, that is, have outgrowths of derived follicles, or are separate follicles which have coalesced Orwin's photographs show more than one fibre in a common sheath at sebaceous-gland level and at a higher level, this, however, in itself is not adequate evidence that one follicle has been derived from another by branching These follicles may equally well have been separately initiated and coalesced so that the fibres come to lie in a common sheath and a common follicular mouth

Auber[2] has indeed demonstrated the occurrence of wool follicles coalescing at a level below that of the sebaceous glands Serial skin sections at levels which include lower levels than that of the sebaceous glands should be made, the follicles traced up and observations confirmed by 'vertical' sections, before deciding whether a follicle has been derived from another one by branching or has coalesced with it. I do not suggest that follicles derived by branching do not occur in breeds of sheep other than the merino, however, in many thousands of serial skin sections from English Romney sheep and lambs that I have examined at all levels I have sometimes seen coalesced follicles, but have not seen truly branched follicles.

Localization of Inhibitors of Neural Differentiation in Chick Embryos

IN testing the hypothesis of specific inhibition in cellular differentiation, I have shown[1] that early chick embryos, when cultured on a nutrient medium which has incorporated in it supernatants of adult and embryonic brain extracts, displayed homologous brain defects in a significant number of cases Since the preparation of subcellular components has become a standard technique for problems of cellular chemistry (see review by Allfrey[2]), this investigation was prompted with the hope of localizing the inhibitory material in the crude brain extracts to a particular cell fraction Accordingly, chick brains were homogenized and subjected to differential centrifugation in order to obtain mitochondrial, microsomal, and soluble protein fractions Earlier investigations of Braverman[3] and Lemcque[4] showed that the nuclear fraction is not involved The procedure used for culturing chick embryos was that of Spratt[5] Since I have found[1] that stages 4 and 5 (ref 6) are the crucial stages for treatment with brain extracts, the assay for inhibitory activity was restricted to the use of these stages

Whole brains from recently hatched chicks totalling 10–15 gm were homogenized in 2 vol (w/v) of 0 25 *M* sucrose–0 004 *M* calcium chloride in a Potter–Elvehjem homogenizer The nuclei and cellular fragments were sedimented in an International refrigerated centrifuge at 700*g* for 10 min The supernatant was then subjected to 15,000*g* for 30 min in a Servall centrifuge This resulted in a white pellet of mitochondria, which was dispersed in phosphate-buffered chick Ringer, *p*H 7 6–7 8 The supernatant was centrifuged at 105,000*g* for 60 min. in a Spinco *L* ultracentrifuge, rotor No 40 This yielded a microsomal pellet, and a supernatant consisting of the soluble protein fraction The former was dispersed in chick Ringer, while the soluble protein fraction was subjected to 18–24 hr dialysis against chick Ringer. All preparations were carried out in the cold room at a temperature of 0–2° C

Aliquots of the samples were taken for quantitative estimations of protein nitrogen using the Kjeldahl method The nutrient medium composed of 0 5 per cent agar, albumen extract, and subcellular fraction was made up in the ratio of 2 1 1 The concentration used in these experiments was 75–90 µgm of protein nitrogen of subcellular component per c c of culture medium

Controls using a myosin preparation obtained through the courtesy of Dr Yujiro Hayashi and adjusted to the equivalent concentrations as with the subcellular fractions in terms of protein nitrogen were used It was intended that the myosin sample, obtained from the leg muscles of the same chicks which were the sources for the brains, would serve as a control of mesodermal origin According to Dr Hayashi, the myosin samples, prepared by a modification of the method of Hasselbach and Schneider[7], showed a single peak when examined by both ultracentrifugal and electrophoretic methods Before use,

Table 1 EFFECT OF SUBCELLULAR FRACTIONS OF BRAIN ON NEURAL DIFFERENTIATION

	Subcellular fraction			
	Mit	Mic	Sol protein	Myosin
Total No of explants	53	67	80	45
Kinds of defects				
Normal	41 (77%)	54 (81%)	15 (19%)	8 (18%)
General defect	7 (13%)	5 (7%)	6 (8%)	—
No development	5 (9%)	5 (7%)	10 (11%)	5 (11%)
Brain limited defect	0 (0%)	3 (4%)	49 (61%)	6 (13%)
Mesodermal and general defect	—	—	—	26 (58%)

the myosin samples were dialysed against chick Ringer solution

The results of this investigation are presented in Table 1 It indicates that the inhibitory factor is localized in the final supernatant or soluble protein fraction For a discussion of the classification of defects see ref 1, since the same system was used in this work In regard to the myosin controls, at concentrations equivalent to the experimental series, that is, 75–90 μgm of protein nitrogen, it was found to be highly toxic for the developing embryos, and resulted in all embryos undergoing no development Consequently, the level has to be lowered considerably, to 15–20 μgm per c c of culture medium. It appeared that the mesodermal defects, which are manifested in circulatory abnormalities, concomitantly lead to generalized defects Thus, a high number of combined mesodermal and general defects were recorded This is not surprising in view of the fact that the myosin preparation represents a relatively purified sample, as compared with the fractions obtained from brain material, which are still rather crude preparations In view of this fact, future work is planned in an effort to characterize and isolate further the inhibitory properties of the soluble protein fraction In this connexion, fractionation of the soluble protein fraction may yield a more potent and pure source of the specific neural differentiation inhibitor.

ENTOMOLOGY

An Apparatus for Observations on the Feeding Mechanism of the Flea

SEVERAL types of feeding chambers have been devised[1] for *in vivo* observations on the feeding mechanism of blood-sucking arthropods, but these chambers, designed to accommodate relatively large creatures (triatomine bugs, tsetse flies and ticks), have proved to be unsuitable for small insects and acarines, such as fleas, lice and mites Our interest in the mechanism of disease transmission by the flea led us to construct a small feeding apparatus by means of which we have been able to undertake extensive observations on the uptake of blood by this insect from the tissues of its host

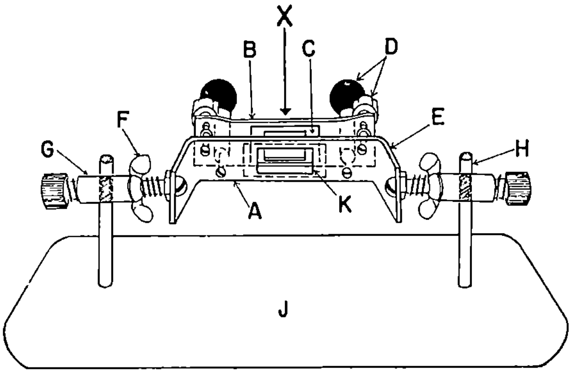

Fig 1 The feeding apparatus as seen from the microscope

The apparatus (Fig 1) consists essentially of two apposable, thin, steel plates (*A* and *B*), each with a centrally placed viewing window (*K*)

Plate *A*, 6·3 cm in length and 1 3 cm. in height, is extended at both extremities to form right-angled extensions (*E*), 1·5 cm. long Each extension is provided with a horizontal bar (*G*) which fixes into a vertical rod (*H*) attached to a carrying table (*J*). The carrying table is clamped to the reversed mechanical stage of a horizontally placed microscope as described by Griffiths and Gordon[2] for an earlier type of feeding chamber

Plate *B*, the same size as *A*, is joined to plate *A* by means of two pairs of adjusting screws (*D*) The adjusting screws (the upper pair is threaded through light springs) enable the plates to be apposed and tilted so that their lower edges can be approximated to enclose the ear of the host (Fig 2)

The viewing windows (*K*), 1 6 cm × 0 8 cm , are each covered by a coverslip (*L*) of a convenient size held in position by an adhesive applied to the edges of the window

An anæsthetized mouse is placed on the carrying table The upper portion of one of its ears, previously treated with a depilatory, is so arranged as to lie over the coverslip on plate *B*, and a strip of foam rubber is then introduced between the plates, one on each side of the window at position *C* (Fig 1) The adjusting screws are gradually tightened until the lower edges of both plates gently grip the ear, the upper edges being kept separated by the springs of the upper pair of screws. In this position plate *B*, carrying the ear, lies at an angle to plate *A* (which is vertical to the microscope tube) In order that the ear should present a flat microscopic field the apparatus is rotated by unloosening the wing nuts (*F*), until the plates have assumed the position shown in Fig 2, and the nuts are retightened

A flea (*N*) anæsthetized with carbon dioxide is then introduced into the chamber, and the upper part is closed off promptly with a strip of foam rubber (*M*) The space enclosed by the lower edges of the plates, the two vertical (*C*) and the horizontal (*M*) strips of foam rubber, forms a completely sealed cell (Fig 2) containing the tip of the animal's ear and the insect

We observed, using this simple apparatus, that *Pulex irritans*, *Xenopsylla cheopis*, *Ctenocephalides felis* and *Atyphloceras multidentatus* normally feed, in non-sensitized mice, directly from the lumen of small blood vessels, and thus may be described as capillary feeders On rare occasions we saw fleas attempting to feed from extravasations of blood resulting from the rupture of vessels, but they never took up any significant quantities of blood from this source

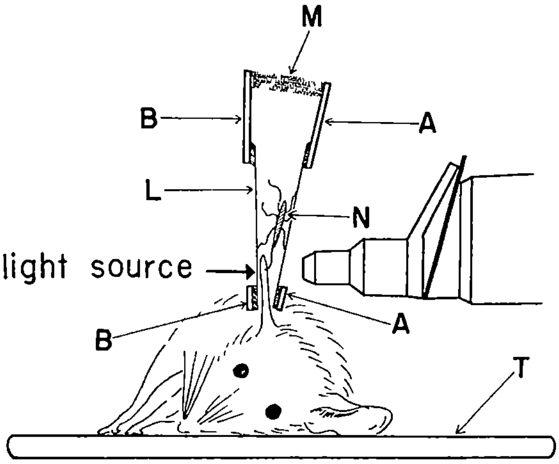

Fig 2 A cross-section through the feeding chamber at position X on Fig 1 (showing a flea feeding on a mouse's ear) after the apparatus has been rotated so that plate B, instead of plate A, is vertical to the tube of the microscope

Feeding appears to proceed in this way the flea introduces its biting fascicle[3]—the paired maxillæ and the epipharynx—into the skin of the host, the maxillæ acting as the cutting organs Having reached a suitable vessel, usually of small calibre, the tip of the epipharynx enters the lumen, the maxillæ (which form the salivary canals) remaining outside The flea then sucks up blood, emitting from time to time, as clearly visible puffs, droplets of saliva in the neighbourhood of the puncture in the vessel wall (but not into the vessel lumen) When the meal is completed the fascicle is rapidly withdrawn, there is surprisingly little damage at the point of introduction of the mouthparts into the skin, the withdrawal hæmorrhage being slight or absent

We wish to acknowledge the assistance of a National Institutes of Health grant, *E*-3571, in carrying out this project and the help of Frank Prince and his colleagues (of C D C station at San Francisco), who kindly provided us with a proportion of the wild and laboratory bred fleas we used in our experiments Histological material, which confirmed our direct observations, was prepared by Rosalie Gill of the Hooper Foundation, to whom we are indebted

Intestinal Proteinases in an Insect, *Calliphora vomitoria* L.

THE properties of the proteolytic enzymes occurring in extracts of insect guts are generally thought to resemble those of vertebrate trypsin[1,2] Only proteinases of alkaline type, with maximum activity about *p*H 8, have been recorded in *Calliphora* adults[3], *Lucilia* larvæ[4], *Musca* larvæ[5], *Stomoxys* adults[6], and *Calliphora* larvæ[7] The only workers to suggest that proteinases in Diptera-Cyclorrhapha do not conform to the general theory, Greenberg and Paretsky[8], reported two distinct proteinases functioning in every stage of the life-cycle of *Musca* with *p*H optima at *p*H 3 and *p*H 8-9.

It has now been established by two techniques that a proteolytic enzyme (or enzymes) with an activity peak about *p*H 3 is produced by cells of the mid-gut of adult females of the blowfly species *C vomitoria*

Proteolytic activity of aqueous extracts of mid-guts of flies fed on meat was determined *in vitro*, over a selected *p*H range, by a colorimetric method Sheep hæmoglobin was used as substrate, prepared in citrate-phosphate buffer, and mixtures of buffered substrate and gut extract were incubated for 3 hr at 38° C After removal of undigested protein, by precipitation (with 10 per cent trichloracetic acid) and centrifugation, the mixture was made alkaline by the addition of sodium carbonate The presence of liberated tyrosine, and tryptophan, was demonstrated by the addition of Folin-Ciocalteau reagent, the intensity of the blue colour which develops being used as a measure of the degradation of the substrate Direct readings of colour intensities were made with an *EEL* portable colorimeter (*O R* 1 light filter) exactly 5 min after the addition of the reagent The graph in Fig 1 was prepared from means of three determinations of proteolytic activity at thirteen *p*H-levels between *p*H 2 5 and *p*H 8 5 The results indicate a high concentration of an enzyme (or enzymes) in gut extracts with an optimum *p*H about *p*H 3 and a lower concentration of an enzyme (or enzymes) with an optimum *p*H at least as high as *p*H 8 5 Controls were prepared at several *p*H-levels and tested for free tyrosine, etc , immediately after preparation, without incubation Readings for these controls approximated to those obtained from digests between *p*H 5 5 and *p*H 7, indicating that there is little enzyme activity within that *p*H-range Further tests

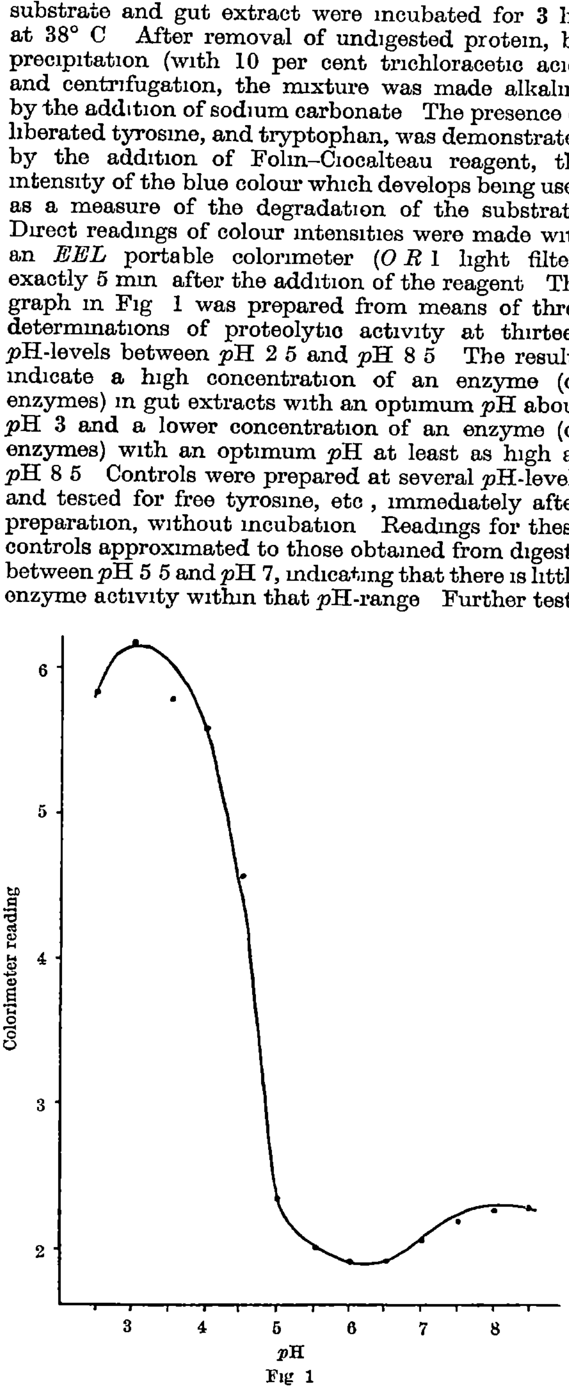

Fig 1

carried out at *p*H 3 with distilled water substituted for enzyme extract showed that the high reading at that *p*H was not due to autolysis of the substrate.

In the second demonstration of proteolytic activity at low *p*H, mid-guts were dissected from 5-day old flies which had fed on meat. The guts were split longitudinally and the peritrophic membrane tube and contents removed. Each gut was then divided into three parts corresponding to the three zones, fore-mid-gut, mid-mid-gut and hind-mid-gut, the contents of which are buffered (as shown by Waterhouse's range-indicator method[9]) at *p*H 5, *p*H 3·6, and *p*H 8. These fractions were then laid on the surface of a thin milk-agar plate of the type normally used for bacteriological work. The milk-agar medium, which contained thiomersalate to inhibit bacteria, was either buffered at *p*H 3·6 or *p*H 8. Preparations were incubated for 24 hr at 38° C. In the low *p*H plates a wide zone of clearing developed around the mid-mid-gut. There was also some evidence of an enzyme active at low *p*H diffusing from the last part of the fore-mid-gut in smaller quantity than that from the mid-mid-gut. Clearing occurred in the immediate vicinity of the hind-mid-gut in *p*H 3·6 plates, but this appeared to be restricted to the range of the gut cells' own buffering effect beyond which the hind-mid-gut enzyme was obviously inactive. In *p*H 8 plates a wide zone of clearing developed around the hind-mid-gut. Thus the results of the quantitative tests have been confirmed and it has been shown that the proteinase (or proteinases) active at low *p*H in the gut of *C. vomitoria* is principally produced by the cells of that zone the *p*H of which is adjusted to suit such an enzyme.

Female blowflies require protein in their diet in order to produce eggs. Males have no such need, but it is interesting to note that they will feed readily on meat, and the milk-agar plate method indicates the presence of the same enzymes in male as in female intestines.

We thank Drs. J. R. Norris and W. R. Rees of this University for valuable discussions and Dr. Ellen Thomsen, Copenhagen, for the initial suggestions.

Home and Distribution of the House Cricket *Acheta domesticus* L.

THE house cricket, *Acheta domesticus*, is generally believed to have moved into Europe and North America from arid and semi-arid areas of northern Africa or south-western Asia[1]. However, during my work on *Acheta domesticus* and related species, I have found evidence which suggests that the question regarding the native country and distribution of *A. domesticus* is more complicated.

Colour and size are unreliable taxonomic characters for separating closely related species of crickets, and the species of the *domesticus* group are remarkably uniform in their outward appearance. However, among the male specimens from various parts of the world, identified as *Acheta domesticus* by Chopard, Uvarov, Dirsh, Kevan, Gurney and other specialists, I have found no less than five species which have no significant external morphological differences but can be clearly separated on the basis of their internal male genitalia. Indeed, two of these species have been experimentally shown to be reproductively isolated[2], but the anatomical reasons for this have only now become clear.

The first step to clear the confusion regarding the taxonomy of the house cricket is to fix the name *Acheta domesticus* L. for one of the five species distinguished in the course of the present studies. The name *A. domesticus*, described from Sweden, should be restricted to the house cricket commonly found in Europe and North America, including the Canadian strain[2]. The males determined on the basis of genitalia were compared with *domesticus* specimens from Sweden, and both sexes taken from the same laboratory-bred stock are being re-described.

Uvarov[1] described on the basis of colour and size *Acheta meridionalis* from Khartoum as a sub-species of *A. domesticus*, and Kevan[3] considered it a wild southern form of the same, but the examination of male genitalia shows that *A. meridionalis* (Uvarov) is a distinct species, known to me also from West Aden Protectorate, Egypt and Fezzan. The examination of the male genitalia shows also that the species referred to earlier as the Pakistani strain[2] is *Acheta hispanicus* Rambur, which I am able to record also from Morocco, Baghdad and West Pakistan. Three more distinct species of the *domesticus* group are known to me from Egypt, East Africa and India.

The specimens of all the species referred to above are preserved in the British Museum (Natural History), London, and their full descriptions, including a re-description of *Acheta domesticus* L. with full synonymy, are ready for publication. Once the identities of the species previously confused with *A. domesticus* are established, it may become possible to build up a better picture of the distribution of the European house cricket (*A. domesticus*), and to determine its native country with greater certainty. The correct identification of these species is also of great economic importance as at least two of them (*A. domesticus* and *A. hispanicus*) are serious pests of irrigated crops in the Indo-Pakistan sub-continent[4], and with the extension of canal irrigation in the arid and semi-arid regions their potential danger continues to increase. I shall be glad to receive material on these crickets either from houses or collected in the field for further studies.

This work was carried out while I held a research fellowship of the South East Asia Treaty Organization and I am grateful for it, and also to Sir Boris Uvarov and Dr. V. M. Dirsh for their advice and help.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, December 11

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W C 1), at 5 30 p m —Prof L S Penrose, F R S "A Theory of Self-reproducing Mechanisms"

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 6 p m —Prof W K Estes "Current Foci of Research in Mathematical Behaviour Theory" * (Last of three Special University Lectures)

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W C 2), at 6 45 p m — Mr G S C Lucas O B E "The Professional Engineer and an Expanding Industry" (Presidential Address)

Tuesday, December 12

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N W 1), at 5 p m —Scientific Papers

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATIONS SECTION (at Savoy Place, London, W C 2), at 5 30 p m — Mr L Lewin "Diversity Reception and Automatic Phase Reception"

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr I D P Wootton "Retention of Aromatic Compounds in Acute Renal Failure" * (Last of seventeen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m — Mr J G G Hempson "Instrumentation Problems in Internal Combustion Engine Development"

UNIVERSITY OF LONDON (in the Beveridge Hall, Senate House, University of London, London, W C 1), at 6 p m —Sir Charles Snow Birkbeck College Foundation Oration

INSTITUTE OF WOOD SCIENCE (at Carpenters Hall, Throgmorton Avenue, London, E C 2), at 7 p m —Dr A C Copisarow "The Role of Forest Products Research in National Economy"

Tuesday, December 12—Wednesday, December 13

BRITISH BIOPHYSICAL SOCIETY (at the Royal Institution, Albemarle Street, London, W 1)—Symposia on "The Structure of Globular Proteins" and "The Function of Proteins", also a session on contributed papers

Wednesday, December 13

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 15 p m —Mr I D Hill "Sampling Inspection and Defence Specification DEF-131"

INSTITUTE OF FUEL (at the Royal United Service Institution, Whitehall, London, S W 1), at 5 30 p m —Mr A Sherry "Power Station Optimization" *

INSTITUTION OF ELECTRICAL ENGINEERS, SUPPLY SECTION (in conjunction with the BRITISH NUCLEAR ENERGY CONFERENCE, at Savoy Place, London, W C 2), at 5 30 p m —Mr J Henderson, Mr G F Kennedy and Dr K J Wootton "Electrical Aspects of Hunterston Nuclear Generating Station"

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 6 p m —Dr E S Hedges "Tin—Its Contribution to Social Development"

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP—NUTRITION PANEL (at 14 Belgrave Square, London, S W 1), at 6 15 p m —Meeting on "Foods Low in Carbohydrates"

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMISTRY GROUP (at "The Feathers", Tudor Street, London, E C 4, at 6 30 p m — Discussion Meeting

SOCIETY OF INSTRUMENT TECHNOLOGY, CONTROL SECTION (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr P K M'Pherson "Application of Complex Plane Methods to System Design"

BRITISH PSYCHOLOGICAL SOCIETY, MEDICAL SECTION (at the Royal Society of Medicine, 1 Wimpole Street, London, W 1), at 8 30 p m — Mr Stephen Black "Hypnosis in Physiological Research"

Thursday, December 14

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S W 1), at 2 30 p m and 5 30 p m —Special Meeting on "New Test Methods"

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (in the Physics Building, Prince Consort Road, London, S W 7), at 5 30 p m —Sir Patrick Linstead F R S "The Prince Consort and the Founding of the Imperial College" (Special Lecture to commemorate the Centenary of the Death of H R H The Prince Consort)

INSTITUTION OF ELECTRICAL ENGINEERS, UTILIZATION SECTION (at Savoy Place, London, W C 2), at 5 30 p m —Dr E R Laithwaite "Oscillating Machines—Synchronous and Asynchronous", Dr E R Laithwaite and Mr R S Mamak "An Oscillating Synchronous Linear Machine"

BRITISH INSTITUTION OF RADIO ENGINEERS, TELEVISION GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street Gower Street, London W C 1), at 6 p m —Symposium on "Constant Luminance Colour Television"

SOCIETY FOR ANALYTICAL CHEMISTRY, BIOLOGICAL METHODS GROUP (in "The Feathers" Restaurant, Tudor Street, London, E C 4) at 6 30 p m —Seventeenth Annual General Meeting, followed by a Discussion Meeting on 'The Assessment of Anti-Aretherosclerotics"

RADAR AND ELECTRONICS ASSOCIATION (in the Lecture Hall of the Royal Society of Medicine, John Adam Street, Adelphi, London, W C 2) at 7 p m —Dr J Gough and Prof F Landgrebe "Loudspeaker Enclosures"

CHEMICAL SOCIETY (in the Lecture Theatre of the Royal Institution, Albemarle Street, London, W 1), at 7 30 p m —Prof C E H Bawn, F R S 'Stereospecific Polymerisation" (Liversidge Lecture)

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W 1), at 7 30 p m —Dr F I C Apted "Sleeping Sickness in Tanganyika, Past, Present and Future"

Friday, December 15

SOCIETY FOR ANALYTICAL CHEMISTRY (joint meeting with the INFRA RED DISCUSSION GROUP, at King's College, Strand, London, W C 2), at 11.10 a m —Meeting on "Applications of Infra Red Spectroscopy to Quantitative Analysis"

Saturday, December 16

BIOCHEMICAL SOCIETY (at the Wolfson Institute, Postgraduate Medical School of London, Ducane Road, London, W 12), at 10 30 a m —Scientific Papers and Demonstrations

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (preferably with a university degree) AT THE FRESHWATER FISHERIES LABORATORY, Department of Agriculture and Fisheries for Scotland, Pitlochry—Establishment Officer, Room 73, Department of Agriculture and Fisheries for Scotland, St Andrew's House, Edinburgh 1 (December 15)

ASSISTANT INSPECTOR (male, graduate in zoology, etc) OF FISHERIES in the Department of Lands, Dublin—The Secretary, Civil Service Commission 45 Upper O'Connell Street, Dublin 1, Republic of Ireland (December 15)

VERTEBRATE BIOLOGIST (with ethological training or experience), for a research post in a Mental Hospital—The Secretary, Birmingham Regional Hospital Board, 10 Augustus Road, Edgbaston, Birmingham 15 (December 16)

ASSISTANT IN THE DEPARTMENT OF GENETICS, for general duties and particularly to assist on work on the genetics of fungi—The Secretary, John Innes Institute, Bayfordbury, Hertford, Herts (December 27)

LECTURER or ASSISTANT LECTURER IN PHYSICS—The Principal, Bede College, Durham (December 31)

LECTURER or SENIOR LECTURER IN GENETICS at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

READER (with special qualifications in educational psychology) IN EDUCATION at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Brisbane and London, December 31)

HEAD (with high academic qualifications and experience in research and in teaching to university degree level) OF THE DEPARTMENT OF PHYSICS—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S W 3 (January 1)

LECTURER (with a registrable veterinary qualification and postgraduate experience in bacteriology) IN BACTERIOLOGY in the School of Veterinary Medicine—The Registrar, Trinity College, Dublin 2, Republic of Ireland (January 1)

BIOPHYSICIST (post-doctoral standing) IN THE ELECTRON MICROSCOPE SECTION, to take part in an investigation of the biological applications of the electron scanning microanalyser (X-ray microspectrometer)—The Secretary, Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge (January 5)

CHAIR, and LECTURER or ASSISTANT IN PHILOSOPHY at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 15)

LECTURER (preferably with a special interest in historical geography) IN GEOGRAPHY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (January 15)

ASSOCIATE PROFESSOR IN EXPERIMENTAL PATHOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 17)

LECTURER (preferably with some experience in steroid and/or carbohydrate chemistry) IN ORGANIC CHEMISTRY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 17)

CHAIR OF AGRICULTURAL CHEMISTRY IN THE DEPARTMENT OF AGRICULTURE, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 31)

CHAIR OF COLOUR CHEMISTRY AND DYEING—The Registrar, The University, Leeds 2 (January 31)

LECTURER (trained and experienced teacher with a degree in chemistry or biology) IN EDUCATION at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Hong Kong and London, January 31)

LECTURER (with at least an honours degree or equivalent qualifications, some postgraduate research experience, and preferably interests in mammalian or human biochemistry) IN BIOCHEMISTRY in the School of Biological Sciences, University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W C 2 and The Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (January 31)

OFFICIAL FELLOW AND LECTURER (mathematician or theoretical physicist) IN MATHEMATICS—The Vice-Provost, Worcester College, Oxford (January 31)

SENIOR RESEARCH ASSISTANT (with a higher degree in chemistry or biochemistry, and several years experience in biochemical research) IN BIOCHEMISTRY, to be engaged full time in a research programme in the field of protein chemistry—The Director of Research, St Vincent's School of Medical Research, Victoria Parade, Fitzroy, N 6, Victoria, Australia (February 28)

ASSISTANT, ASSOCIATE OF FULL PROFESSOR OF PSYCHOLOGY and an ASSISTANT PROFESSOR OF PSYCHOLOGY—Prof J R Royce, Head, Department of Psychology, University of Alberta, Edmonton, Alberta, Canada

ASSISTANT PROFESSOR OF PHYSICS—Prof C E Challice, Department of Physics, University of Alberta, Calgary, Alberta, Canada

ASSOCIATE PROFESSOR OF ASSISTANT PROFESSOR IN THE DEPARTMENT OF PHYSICS—Head of the Department of Physics, Victoria College, Victoria, B C , Canada

HISTORICAL ARCHÆOLOGIST (graduate with specialization in archæology, approximately four years experience in conducting archæological investigations, including the excavation of historical ruins) in the Department of Northern Affairs and National Resources, Louisbourg, Nova Scotia, Canada, to undertake all archæological excavations in connexion with the restoration of the Fortress of Louisbourg National Historic Park—Civil Service Commission of Canada, Ottawa, Ontario, Canada

MASTER TO TEACH MATHEMATICS to public school scholarship standard—The Headmaster, Lathallan School, Montrose Angus

PHYSICISTS or ELECTRICAL ENGINEERS (preferably with experience in one or more of the following fields high vacuum, R F techniques (75 mc /s), high power rectifier and pulse circuits, general electronic instrumentation and controls) IN THE DEPARTMENT OF PHYSICS, to assist with the construction and commissioning of a large heavy ion linear accelerator—The Assistant Director, Linear Accelerator Laboratory, Physics Department, The University, Manchester

RESEARCH ASSISTANT (with a degree in engineering and some knowledge of mechanical vibration) IN THE DEPARTMENT OF ENGINEERING, for work on certain problems related to the vibration of turbine blades—The Secretary, The University, Old College, South Bridge, Edinburgh

RESEARCH FELLOW (recent or prospective Ph D graduate in biochemistry, physiology, nutrition or allied subjects) IN THE FIELD OF NUTRITION IN THE DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY—The Secretary and Registrar, The University, Southampton

SCIENTIFIC OFFICER (with an honours degree in chemistry or agricultural chemistry, A R I C or an equivalent qualification, and particularly interested in analytical chemistry) IN THE CHEMISTRY DEPARTMENT, to take part in researches on the composition of milk—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref 61/32

SENIOR LECTURER IN ORGANIC CHEMISTRY—The Registrar, The University, Leicester

SENIOR LECTURER IN PHYSICS and a LECTURER IN PHYSICS—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N 7

SENIOR LECTURER or LECTURER (with a knowledge of West African livestock and feeding-stuffs, especially grass) IN AGRICULTURAL BIOCHEMISTRY AND NUTRITION at the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1

SENIOR TECHNICIAN, for histological research—The Secretary, The Royal Free Hospital, Gray's Inn Road, London, W C 1

PROFESSIONAL CIVIL SERVANTS IN BRITAIN

IN his speech at the sixteenth annual delegate Conference of the Institution of Professional Civil Servants last May, Mr Stanley Mayne, who was then retiring from the office of general secretary, commented at some length on the position of three scientific classes in the Civil Service He noted a feeling of frustration in the experimental officers class, and emphasized that the scientific officer class was not attracting the numbers it needed In particular, promotion from assistant engineer to executive engineer was no longer a matter of selecting an officer best fitted for the job, but of trying to persuade someone to accept the post, because the reward for promotion was so insignificant and there was no acceptable compensation for any consequent removal and disruption of social life. Mr Mayne also referred particularly to the position of those in high professional posts in the Service, where salaries were still disproportionate with the responsibilities and with those paid for the corresponding professional positions outside

Mr Mayne made it clear, in pressing these claims, particularly those of certain leading professional posts, for salaries at the same level as those of 'permanent secretaries', that the Institution of Professional Civil Servants recognized that it was not simply a matter of pay but of status also The professional and scientific Civil Service had suffered too long because its leading members had been valued too cheaply by the Service, and because science and technology are in general valued too cheaply With admirable restraint and a firm appeal to reason, as well as a deep sense of responsibility to the community, Mr Mayne pressed the Institution's position, while urging that it should never forget that it was part of a larger world

That speech alone demonstrates the existence of a very significant element of morale in the questions of salaries for professional Civil servants, and perhaps especially as regards the scientific classes Because of that, the application of the pay-pause announced by the Chancellor of the Exchequer at the end of July has seriously strained staff relations in the Service, and Mr Richard Nunn, who has succeeded Mr Mayne, points out that because of the continued delay in dealing with claims submitted much earlier, professional Civil servants are beginning to believe that the Treasury is using the pay-pause not only to delay salary increases but also to stop negotiations altogether From what he has written in recent issues of *State Service*, it appears that confidence in the staff consultation organization within the Civil Service is being seriously undermined.

Clearly questions of morale are deeply involved, and although Mr N Walker claims that his book, published a short time ago*, is no more than a factual study of the psychological aspects of employment as a desk worker, morale in the Civil Service can scarcely be considered in relation to one particular class of workers alone Moreover, Mr. Walker points out at the start that his concern with morale arises from an attempt to study the efficiency of office work and to offer suggestions for improving it This is not merely a matter of pay, of working conditions, or of improving the chances of promotion, although these can all be contributory factors, if adjustment is limited to possibilities

Mr Walker's book has little of direct interest to the scientist or technologist, except from the point of view of a study of human relations and of problems with which the manager of any sizable department, whether technical or not, may be confronted He does not altogether ignore the professional classes of the Civil Service, though his questionnaire touched comparatively few of these, and only three of many professions in the Service Among those in the small Ministry which he studied, and whose work to some extent was creative, he found a high degree of satisfaction with their work, but those in a large Ministry were much more critical of the system Perhaps even more significant, professional workers in both Ministries showed little confidence in the administrators Mr Walker himself recognizes that this may be a symptom of the belief that decisions taken by laymen who are administrative colleagues or by their Ministers have too little regard to the technical advice or needs of the professional classes

This is part of the problem of relations between the administrative and the scientific and other professional grades, and lay outside the scope of Mr. Walker s investigation While he makes some interesting comparisons between Civil servants and the office staff of private companies to whom his questionnaire was also circulated, and discredits some common hypotheses while confirming others, it leads to little in the way of conclusions He failed to find any reason for young male clerical officers resigning in such large numbers, or for the increase in the sick-rate with the number of workers in the office building, or to suggest any sort of training which might make office workers better at managing subordinates On morale itself, it seems rather to raise the unanswered question What makes work interesting ?; and although the differences between the office staff in the two Ministries and in the private firms covered by Mr. Walker's investigation do not suggest that any one is preferable to the others, one important difference is again brought out which can scarcely be over-emphasized The office worker in the Civil Service is not altogether uncritical of the Service itself and its efficiency, frequently he is critical of laxity in discipline, where

* *Morale in the Civil Service a Study of the Desk Worker* By Nigel Walker Pp viii+302 (Edinburgh At the University Press, 1961 Distributed by Thomas Nelson and Sons, Ltd) 30s net

this is reflected in inefficiency The Service, however, is highly sensitive to criticism from outside, especially ill-founded or ill-informed criticism, and the bearing of this on morale and efficiency in the Service generally is possibly closer than Mr Walker himself indicates It could well encourage the group loyalty or *esprit de corps,* often so important in efficiency, to lead to a blindness to faults which undermines efficiency in other ways

Apart from the comments on the need for restraint and fairmindedness in public criticism, the two most important points made in Mr Walker's book are the reminders that we need to know much more about the causes which lead to satisfaction in work and also about the relations between the professional and administrative officers There is still the feeling that the work of the former is neither properly valued nor clearly understood, and that Mr Walker directs even passing attention to this serious problem is sufficient reason for the scientist and technologist to take note of his book

While those professional Civil servants who occupy very senior positions are given both status and remuneration more in accordance with their responsibilities, as is shown by the annual lists of special promotions, there must be many others whose conditions of enployment could be much improved Perhaps Mr Walker's book might be put in the hands of the administrative classes of the Civil Service, where its readers would learn something of the outlook of their opposite numbers on the scientific side, to the ultimate benefit of the whole of the Service

THE HALLEY BAY EXPEDITION OF THE ROYAL SOCIETY

The Royal Society International Geophysical Year Antarctic Expedition

Halley Bay, Coats Land, Falkland Islands Dependencies, 1955–1959 General Editor Sir David Brunt Vol 1 Introductions, Aurora and Airglow, Geomagnetism Pp xv + 405 + 12 plates 140*s* , 23 dollars

THE origin, organization and execution of the project known as the International Geophysical Year, and in particular the participation of the United Kingdom, are well known[1] Full details concerning the Royal Society's International Geophysical Year Expedition to Halley Bay, Antarctica, during 1955–59, are given in the introduction by Sir David Brunt, former Physical Secretary of the Royal Society, to the volume under review The British National Committee for the International Geophysical Year was set up by the Council of the Royal Society on December 11, 1952, and formal approval was given by this Committee on March 1, 1955, to the general proposals for setting up a station in the Antarctic The necessary support from H M Treasury and the Colonial Office was forthcoming, and the advance party, with Lieutenant-Commander D G Dalgleish as leader, left Southampton on November 22, 1955, a landing was made on January 11, 1956, at a suitable point *c* 75° 31′ S , 26° 37′ W , which was later named Halley Bay

The main party left England during November 1956 under the leadership of Colonel R A Smart, in the M S *Magga Dan,* along with the main party of the Commonwealth Trans-Antarctic Expedition The Antarctic Sub-committee set up by the British National Committee had planned in detail a programme of observations on meteorology, geomagnetism, aurora and airglow, ionospheric physics, glaciology and seismology, including an extensive programme of radio-astronomical observations A further visit was made to the base during the Antarctic summer 1957–58, when Colonel Smart, following his wish expressed at the time of his appointment in 1956, returned home and was succeeded as leader by J MacDowall

An outstanding criticism of the International Polar Year expeditions of 1882–83 and 1932–33 had been the long delay in publishing some of the observations This consideration was doubtless in the minds of the Antarctic Analysis Subcommittee set up to supervise the publication of the scientific results of the present expedition, and it is commendable that Volume 1, dealing with aurora and airglow, and geomagnetism, should have appeared so soon The observations themselves are preceded by a vivid narrative account of the establishment and maintenance of the base, this account is illustrated by a series of excellent photographs, which in particular show the measures taken to combat the accumulation of snow, amounting even on a flat drift-free surface to 3 ft /year

The visual and photographic observations of the aurora are discussed by S Evans and G M Thomas, an all-sky camera was used whenever conditions were favourable Some very beautiful photographs, together with a table of movements of auroral features, are given in this volume An airglow photometer, sensitive to a band of infra-red wave-lengths of 7,400–11,300 Å , was operated as conditions permitted, the report by G M Thomas, who was observer of auroral and airglow phenomena to the main party, lists the mean nightly airglow intensities, which constitute a valuable record inasmuch as it was possible in general to recognize those occasions on which the measured zenithal intensity was enhanced by light from auroræ

The geomagnetic observations occupy by far the greater part of the volume The laboratory was a non-magnetic hut with its centre line along the observed magnetic meridian, it was at least 110 m from any large ferrous objects, and tractors were not allowed within 100 m of the hut The observatory was built on a floating ice-shelf which moved slowly and steadily seaward The foundations for the recording and absolute instruments were wooden piles driven 6 m into the snow Continuous registration of the horizontal force (H), the declination (D) and the vertical force (Z) were made by two independent recorders of the La Cour type The absolute instruments were three quartz-fibre horizontal-force magnetometers, two balance magnetometers for vertical force, and a portable unifilar magnetometer-inductor The discussion by J MacDowall and A Blackie of the geomagnetic work is too detailed to summarize here It contains the diurnal variation (including a harmonic analysis of H, D and Z), a detailed examination of K-indices, Q-indices and the absolute daily range Diagrams are given of the vector field changes, and tables are included listing (*inter alia*) the hourly mean values of the three components of geomagnetic force for every day, the 3-hourly K-indices, and the Q-indices for consecutive intervals of 15 min The volume concludes with reproductions of the complete series of magnetograms from April 30, 1957, to December 31, 1958

In all, this work presents the results of a prodigious amount of labour It is well set-out, and the typography is excellent The Royal Society and the authors are to be congratulated on their fine achievement
R STONELEY

THE TEACHING OF QUANTUM MECHANICS

Introduction to Quantum Mechanics

By Prof Robert H Dicke and Dr James P Wittke Pp xi+369 (Reading, Mass , and London Addison-Wesley Publishing Company, Inc , 1960 66*s*)

Problems in Quantum Mechanics

By I I Gol dman, V D Krivchenkov, V I Kogan and V M Galitskii Pp iii+394 (London Infosearch Limited, 1960 Distributed by Cleaver-Hume Press, Ltd) 42*s*

Problems in Quantum Mechanics

By I I Gol'dman and V D Krivchenkov Edited by Prof B T Geilikman Translated from the Russian by E Marquit and E Lepa Authorized revised edition Pp viii+275 (London and New York Pergamon Press 1961) 50*s*

AFTER many years of famine in the supply of quantum mechanics text-books, there is now an abundance and more titles keep appearing It is possible therefore to be fairly critical in deciding which text-books to recommend to students Quantum theory is gradually taking a larger part in undergraduate training in general and theoretical physics, and the type of book required at the undergraduate level is not for example, Dirac's, which is too difficult, or that of Landau and Lifshitz which is too big and thorough

Prof Dicke and Dr Wittke have written their text for the first postgraduate physics year at Princeton, and it covers much the same ground as that at many British universities (it should be all), in the third year of honours physics All the essentials of quantum theory are covered, and the late chapters of the book cover the effects of strong fields on atoms, scattering theory, the effect of statistics on the two and many-body systems, and on quantum statistical mechanics There is a surprising and serious omission from the contents since the uncertainty relation between energy and time is never mentioned On the whole it is well written, with the difficulties that a beginner experiences well aired Useful sets of examples are appended to each chapter But it can be criticized in that several mathematical statements are not precise and the same lack of precision shows up in several of the discussions of points of principle For example Why should Hermites polynomials have to terminate ? Why should they be polynomials at all ? Why should the reader accept, without proof, that $(\exp ikr)/r$ is the Green function for scattering and not $(\exp - ikr)/r$? The discussion of orbital and spin angular momentum make these appear only trivially different, and in discussion of what Dirac calls the Schrodinger and Heisenberg 'pictures', the word representation is confusingly used to mean picture as well as its mathematical meaning with respect to a basis There are several other minor inaccuracies and obscurities, and a general tautening up of statements could be made throughout the book without making it longer or more difficult In spite of these drawbacks it is an attractive book and beautifully produced

The two collections of examples present a curious situation for they are effectively the same book, being translations of a set of problems with full solutions, used by Drs Gol'dman and Krivchenkov in teaching a course of quantum mechanics based on Landau and Lifshitz's text The volume from Infosearch has added further problems from a comparable set by Kogan and Galitskii, while that from Pergamon is based solely on Gol'dman and Krivchenkov, though from an extended and revised version The latter states it is the 'authorized version', which may account for the price difference As it stands the Infosearch edition is considerably larger and clearly the 'best buy' These problems cover much more ground than say Dicke and Wittke, and are suitable for theoretical specialists With the book of Landau and Lifshitz they throw up a powerful challenge This is how quantum mechanics is taught to theorists in Moscow Are British theorists taught as thoroughly ? Moreover, in those universities where they are, do the students also reach the same standard in hydrodynamics, physical kinetics, elasticity, etc , as the introductions to the Landau and Lifshitz texts assure us the Russian theorists do Regretfully one must give the answer that scarcely anywhere in Britain is this standard aimed at, let alone achieved.

S F EDWARDS

THEORY AND TABLES OF THE BLUE SKY

Tables related to Radiation emerging from a Planetary Atmosphere with Rayleigh Scattering

By Kinsell L Coulson, Jitendra V Dave and Zdeněk Sekera Pp x+548 (Berkeley and Los Angeles University of California Press, London Cambridge University Press, 1960) 116*s* net

ONE of the best-known of the many fundamental contributions to science made by Lord Rayleigh during his long career was his discovery of the law of molecular scattering (named after him) and its application to the explanation of the colour and polarization of the sunlit sky The problem of the diffuse reflexion and transmission of sunlight in an atmosphere scattering it in accordance with Rayleigh's law has since become one of the classical problems of mathematical physics, of particular interest to meteorology Many efforts were made toward its solution—culminating in the well-known work by Chandrasekhar, who succeeded in constructing its exact solution in terms of the so-called X- and Y-functions satisfying four pairs of simultaneous integral equations—but, alas, these equations turned out to be non-linear and of the type which resolutely defies any possibility of an analytical solution

Yet, in order to learn what these functions are capable of revealing, it is necessary to evaluate them numerically and insert in various relevant expressions The construction (by successive approximations) of numerical solutions of the respective equations has indeed been undertaken recently by the authors of the volume under review, on an impressive scale, using the facilities of the Watson Scientific Computing Laboratory in New York and of the Institute for Numerical Analysis of the U.S. National Bureau of Standards at Los Angeles. From the functions X and Y so obtained, the Stokes parameters of the radiation emerging in different directions at the top and at the bottom of the atmosphere have been computed for different elevations of the Sun and different reflectivities of the ground. The results of these computations, performed by the authors at the Data Processing Centre of the University of California at Los Angeles, are then presented in this book.

The volume itself consists largely of an impressive set of tables, containing accurate data which should meet any conceivable problem encountered in the field of atmospheric optics for a long time to come, and represents a permanent contribution to the literature on physical meteorology. We can indeed agree with Chandrasekhar's words in the foreword to this book that “ with the publication of this volume, comprising the work of Dr. Sekera and his collaborators, the problem that was formulated by Rayleigh in 1871 has now at last found its complete solution”.

Zdeněk Kopal

STRUCTURE, LIFE-HISTORY AND DISTRIBUTION OF *GNETUM*

Gnetum

By P. Maheshwari and Vimla Vasil. (Botanical Monograph No. 1.) Pp. xii+142. (New Delhi: Council of Scientific and Industrial Research, 1961.) Rs 20.00, 40s.

GNETUM is a genus consisting of rather more than thirty species of which most are woody climbers, but some are shrubs and small trees. It is confined to certain humid regions in South-east Asia, West Africa and the north-eastern parts of South America. It was at one time classified with *Ephedra* and *Welwitschia* in the order Gnetales, but it is now generally accepted that these last two genera are not very closely related to *Gnetum*, so that the order Gnetales is now thought of as consisting of this one genus. The chief botanical interest of the genus is that all its members exhibit, in their floral morphology, embryology and in the structure of their vegetative organs, a mixture of angiosperm and gymnosperm characters. In consequence the genus has been much discussed whenever the origin of the flowering plants is under consideration. To those botanists who are familiar with *Gnetum* mainly on account of its phylogenetic interest it may come as a surprise to learn that *Gnetum gnemon* is cultivated for the sake of its edible seeds, that fibre from the bark is used to make fishing nets and ropes, and the wood of old trees is used in cooperage.

The book under review is the first of a series of botanical monographs that is to be produced by the Indian Council of Scientific and Industrial Research. The senior author, who is professor of botany at Delhi, is already well known for the extensive programme of research carried on in collaboration with his pupils and associates, on the morphological aspects of the embryology of the flowering plants. His *Embryology of Angiosperms* is also much used as a work of reference and by students. In the monograph now under review the authors integrate and summarize all that has been done on the geographical distribution, morphology, anatomy and embryology of *Gnetum*. The relationships of the genus to the angiosperms and gymnosperms and also with *Ephedra* and *Welwitschia* are also fully discussed. The book is well illustrated by distribution maps for the species, as well as by line drawings and photographs, all of which are of excellent quality and well reproduced, many of these illustrations being original. There are a comprehensive bibliography and a single index to authors, plant names and subjects.

The book, which is well printed and reasonably well bound, can be recommended to research workers, teachers and students who will no doubt welcome this modern treatment of a topic that has been of interest for many years. Readers will find, however, that the authors are cautious in drawing phylogenetic conclusions, for the text ends with these words: “Thus *Gnetum* remains largely a phylogenetic puzzle. It is gymnospermous, but possesses some strong angiospermic features”.

C. R. Metcalfe

WORLD FOOD PROBLEMS

World Review of Nutrition and Dietetics

Vol. 2. Edited by Geoffrey H. Bourne, assisted by Eileen M. H. Wilson. Pp. viii+245+14 plates. (London: Pitman Medical Publishing Co., Ltd., 1960.) 60s net.

THE second volume in this series is slightly shorter than the first, but, as the editor remarks in the preface, it “spreads its international net even wider”. There are two contributions from the United States and one each from France, Sweden, South Africa, New Zealand, Switzerland and the United Kingdom. The subject-matter again covers a wide range, as the titles of the following four contributions out of a total of nine indicate: “Proteins and Hæmatopoiesis”, “The Effect of Malnutrition on the Eye, with Special Reference to Work with Experimental Animals”; “The Microbiology of Digestion”, “The Role of Carotene and Vitamin A in Animal Feeding”. The reviews are written by well-informed and experienced workers, who between them list some 2,000 references.

In the preface to Volume 1 the editor expressed the hope that each review would “provide a critical evaluation of the field” and added that “the author's interpretation, his views and his theorising will be welcomed as an integral part of his article”. These aims have not been fully achieved. Some of the authors draw some conclusions from their extensive reviews, other confine themselves to a survey of the literature which ends abruptly without summary or comment. It would surely be useful if authors of multi-reference scientific reviews would attempt more often to summarize the salient points and briefly discuss the key question: Where do we go from here? This might help towards discarding literature which has contributed at some stage to the advance of knowledge, but no longer needs to be consulted.

With this second volume, the *World Review of Nutrition and Dietetics* is fully launched and on the way to establishing itself as a publication of importance to research workers in nutrition and associated fields throughout the world. It is well printed and produced. The editor is to be congratulated on the high standard attained.

W. R. Aykroyd

Biological Education in American Secondary Schools, 1890-1960

By Paul De Hart Hurd (Biological Sciences Curriculum Study Bulletin, No 1) Pp ix+263 (Washington, D C American Institute of Biological Sciences, 1961) 4.75 dollars

TO help in the preparation of new material for American schools, Dr Paul De Hart Hurd of Stanford University was invited to make a historical critique of the development of secondary school biological education in the United States His report describes the investigations that he has made of the teaching of biology in the American high school covering the period 1890–1961, and is limited to consideration of curriculum development and investigations of classroom and laboratory learning. Training of teachers, professional training of biologists and special programmes for high-school students are not considered. The work would be of interest to students of the history of biological education Teachers of biology in Britain could find many parallels to the questions which Dr Hart Hurd raises about contemporary teaching in the United States , they would also wish that some of the answers had been forthcoming

Histologie und Mikroskopische Anatomie des Menschen

Von Prof. W. Bargmann Dritte, verbesserte Auflage Pp xvi+820. (Stuttgart. Georg Thieme Verlag, 1959) 69 60 D M

THIS is the third edition of Prof Bargmann's monumental work, which originally appeared in two volumes In keeping with—as the author says—"the renaissance in structural biological research" which we witness at the present time, the original text has been revised in many respects. This is particularly so in the chapters dealing with cells and tissues generally Accounts of ultra-structure as revealed by electron microscopy have been added *per se* or skilfully woven into the text The neurone theory has been restored to its appropriate place, full descriptions are given of the fine structure of synapses, sensory epithelia, Ranvier's nodes, motor end-plates and of the myelin sheath. The reality of bile capillaries and Disse's space is attested and the 'sex chromatin' fully discussed, to mention only a few items, but 'amitosis' as a mode of cell proliferation still looms unduly large With the fast advance being made in the field of electron microscopy, keeping up to date is almost impossible, but it is regrettable that some of the exciting and illuminating pictures which have been obtained with the electron microscope of skeletal muscle are not included

Where the book scores over the many others available in the field of histology is in the treatment of the microscopic anatomy of the connective tissue apparatus, its intimate architecture and the relationship of particular designs to the function of individual organs. First-class descriptions are given of complex mechanical, elasto-muscular arrangements and, in some instances, also of intricate vascular patterns

The compass of the book being exceptionally wide, it includes many embryological data The value of these could be enhanced by some more illustrations of what are, after all, very complex situations and events, and, sometimes, a single picture would aid and clarify a very condensed description Similarly, the chapter on the central nervous system would gain by additional illustrations Valuable information is given on post-natal developmental processes and on senile changes.

The masterly style bears the stamp of the dynamic personality of the author, makes fascinating reading and brings microscopic anatomy very much to life There can be no doubt that the interest of the student must be aroused and highly stimulated by such a vivid account, at the same time, the student would do well to keep an open mind towards many problematic issues which have remained somewhat hidden in this presentation Key references to the literature are given at frequent intervals, and photographs of famous microscopists and brief footnotes here and there direct attention to historical aspects of the subject. F JACOBY

Coir

Its Extraction, Properties and Uses Pp v+54 (New Delhi Council of Scientific and Industrial Research, 1960) Rs 6 00, 10*s*

THIS small book of some fifty pages gives a good account of the Indian coir or coconut fibre industry, India being one of the main producers of this important commercial fibre. The book is the result of a decision made by the All India Board of Technical Studies in Textile Technology in 1950 to collect and collate available information on the coir industry This has now been presented in condensed form under such headings as extraction of coir, structure and properties of the fibre, spinning, weaving, dyeing and printing, ropes and cordage, other uses, marketing and trade

The value of coir as a fibre lies in its resilience or elasticity and its durability and damp resistance, properties which render it so well suited for matting or floor-covering and certain types of cordage One of the features of its production is the traditional retting process with the drawbacks (evil smell) that go with it It also involves a considerable loss of potential plant food (potassium and phosphorus). Reference is made to various alternative methods of extracting the fibre from the husk, mechanical and chemical, that have been put forward from time to time. For various reasons, however, the old method prevails in what is still essentially a cottage industry in India A number of interesting photographs and a short bibliography are included

Indian Tobacco

A Monograph Pp xxii+413+154 photographs (Madras Indian Central Tobacco Committee, Ministry of Food and Agriculture, Government of India, 1960) Rs 36.00, 72*s* , 10 dollars

THIS book, which contains a great deal of useful information on the cultivation, production and use of tobacco in India, owes its origin to the Indian Central Tobacco Committee and is the work of several authors, including past and present directors of tobacco research As the Indian Minister for Agriculture points out in his foreword, India is faced with a land shortage or crisis, with simultaneous pressure from food and non-food crops Tobacco falls into the latter category and cannot claim priority. Steps to increase yield from the existing acreage are therefore all the more imperative This comprehensive work should play a useful part in this connexion

Tobacco cultivation in India differs from that in most other important tobacco growing countries because in India the crop has to be grown under monsoon conditions The book may be of special value to those concerned with tobacco cultivation in other parts of the world where monsoon or similar climatic conditions prevail It is divided into three parts In the first part soils, climate, botany, cultivation, curing, pests and diseases, etc, are dealt with Part 2 deals in detail with the five basic types of tobacco produced in India, namely, flue-cured tobacco, bidi tobacco, cigar and cheroot tobacco, hookah tobacco, chewing and snuff tobacco The third part is concerned with marketing

The book is not without certain errors, one of the most lamentable being the statement in the second paragraph of the introduction that Christopher Columbus discovered tobacco in his voyage from Persia to Spain on the island of Tobago!

Transactions of the Society of Rheology

Vol 5, 1961 Edited by E H Lee Pp ii+382 (New York Interscience Publishers Inc, London Interscience Publishers, Ltd, 1961) 10 50 dollars

THE 1961 volume comprises the majority of the papers presented at the thirty-first annual meeting of the (American) Society of Rheology in Pittsburgh (Pa) and includes symposia on the mechanics of continua and on the rheology of suspensions as well as nearly twenty papers concerned with other topics I remember criticisms at the first meeting (1929) that rheology was too mathematical for the practical man, but, more than thirty years later, it seems that workers in many industries are quite able to cope with triple integrals and tensor notation

Like all sciences, rheology has its fashions At the moment, normal stresses ('Weissenberg effects') and dynamic mechanical properties lead in the theoretical field, and die entry and extrusion problems on the practical side High polymers are still in the lead among the materials of interest, but a paper on the rheology of blood reminds us of increasing attention to biological applications

The Bingham Medal for 1960 has been awarded to Dr B H. Zimm for outstanding work linking optical with rheological methods in the study of macromolecules and the determination of their molecular weights

Many of the papers are very short, but the authors' addresses are given and readers will doubtless write for reprints of longer articles

The *Transactions* are, as always, well printed and produced but the price for a volume of this size is rather high

G W SCOTT BLAIR

Technical Data on Fuel

Edited by H M Spiers Sixth Edition, completely revised Pp xi+360 (London British National Committee, World Power Conference, 1961) 60s net

THIS sixth edition of a well-known and much-used reference book constitutes a marked advance on its predecessors, for it contains more information in the form of both text and tables and the size of the page has been increased This may be a disadvantage to the worker who wishes to have a readily portable book of useful handiness, but the greater wealth of information compensates amply for the change in character The tables and diagrams are brought into better relation with the text and most of the tables are placed on single pages In general it will be agreed that the changes will be approved by fuel technologists. The contents of the book have been extensively revised, tables have been recalculated where necessary, or replaced on the basis of more recent or more trustworthy data, and the conversion factors and the symbols for units have been brought into conformity with British Standard specifications These features that have been confirmed in use constitute a worthy improvement The sections that have been extensively revised or completely re-written include many subjects in which technical advances are bound to move with the times, and the new information is therefore all the more welcome

Of the entirely new topics included in this new edition mention should be made of information relating to atomic and nuclear fuels, the viscosity blending of oils and flow in fluidized systems A table of additive viscosity functions derived from the usual type of viscosity blending chart enables the viscosity of a blend of several fuel oil components to be estimated with considerable accuracy Since the use of fluidized beds is coming more into use in fuel technology the information provided is typical of the general character of the advancement shown in this edition The general legibility of the text, charts and tables is a noteworthy feature of the book

R J SARJANT

Symposium on Pilot Plants in Metallurgical Research and Development

Held at the National Metallurgical Laboratory, Jamshedpur, India, February 15th to 18th, 1960 Edited by R M Krishnan (Organized by the National Metallurgical Laboratory, Jamshedpur) Pp 304 (Calcutta The Technical Journals of India Private, Ltd., 1960) n p

THIS symposium drew a large gathering of scientists and metallurgists from ten overseas countries as well as equally important representatives from metallurgical science and industry from India Formal papers presented totalled 29, of which 16 were by foreigners and 13 by Indians There were also three lectures by visitors All papers and lectures are reprinted in full together with the discussions

The National Metallurgical Laboratory at Jamshedpur is concerned with ferrous and non-ferrous problems, and while part of its activity is devoted to laboratory research in order to exploit to the full the mineral resources of India, a major emphasis has been placed on the design, erection and operation of pilot plants The scope of these pilot plants ranges from the basic chemistry of metals to financial evaluations of ambitious metallurgical processes Many of these experiences were reported

Some of the papers directed attention to the uses and limitations of pilot plant studies and others described in detail many of the successful pilot plants operating in the world These included coking studies, cupola and blast-furnace operation, ore sintering, oxygen steel-making, refractories, continuous casting, mineral dressing, etc

It is clear from the papers and discussion that most people present fully appreciated the gulf which exists between initial laboratory findings and economically attractive commercial operations They also realized the vital part that well-planned pilot plant investigations can play in bridging this gap This book forms a valuable collection of experiences on this topic and covers a wide range of industries

E W VOICE

ANALYSIS OF THE RELATIONSHIP BETWEEN DEPOSITION OF LONG-LIVED FISSION PRODUCTS AND LEVEL OF ACTIVITY IN MILK

By Dr. W ANDERSON, L. K BURTON and J. O. CROOKALL

Physics Department, Institute of Cancer Research Royal Cancer Hospital, London, S W 3

IN recent years attention has been focused on the mechanisms of transit of fall-out radionuclides in food chains, particularly the steps leading to the contamination of milk One of the main issues to be resolved is the extent to which the levels of activity in foods are determined, on one hand, by the deposit of activity accumulated over the years in the top of the soil, and, on the other hand, by the proximate deposition The evidence available on strontium-90 and cæsium-137 concentrations in milk produced in Great Britain indicates that, up to the present time, the activity-levels have been determined largely by the rate of fall-out at or near the time of production of milk[1-4] However, the relative importance of the contributions of activity from the cumulative and current deposits may be expected to change with the changing fall-out conditions, and it would therefore be useful to obtain a more quantitative expression of these relationships than is available at present Since marked changes in the rate of fall-out occurred during the period 1958–60, it is now possible to tackle this problem by correlating the levels of activity for milk, for various open-pasture feeding months, with the corresponding cumulative and current amounts of deposition

In the present article we report the levels of strontium-90 and cæsium-137 occurring in milk produced in west Cardiganshire, Wales (Felinfach creamery) throughout 1960, and examine these results in relation to the situation for the same series of samples in 1958–59 It should be noted that the activity values reported here refer to levels in milk produced in a single area and they should not be taken to represent the average levels for Britain as a whole On the other hand, except in the case of special areas where the rate of growth of herbage is abnormally low[4], the variation in levels of activity for milk between different regions of the country is largely attributable to difference in rainfall[1-3,5] This indicates that the relationships between levels of activity for milk and deposition-levels in the different regions are broadly similar in nature to those discussed below for the Felinfach region

The milk sampling and measuring techniques used in this work have already been described[3,6,7] Samples of dried skimmed milk, each representative of a total day's production, were obtained at weekly intervals, and measurements were made on bulked samples, compounded from four consecutive weekly samples Thus, each measured value represents approximately the mean level of activity in the milk drawn from the Felinfach area, averaged over a 4-weekly period It may be noted that the full open-pasture feeding period in the area extends from May to October

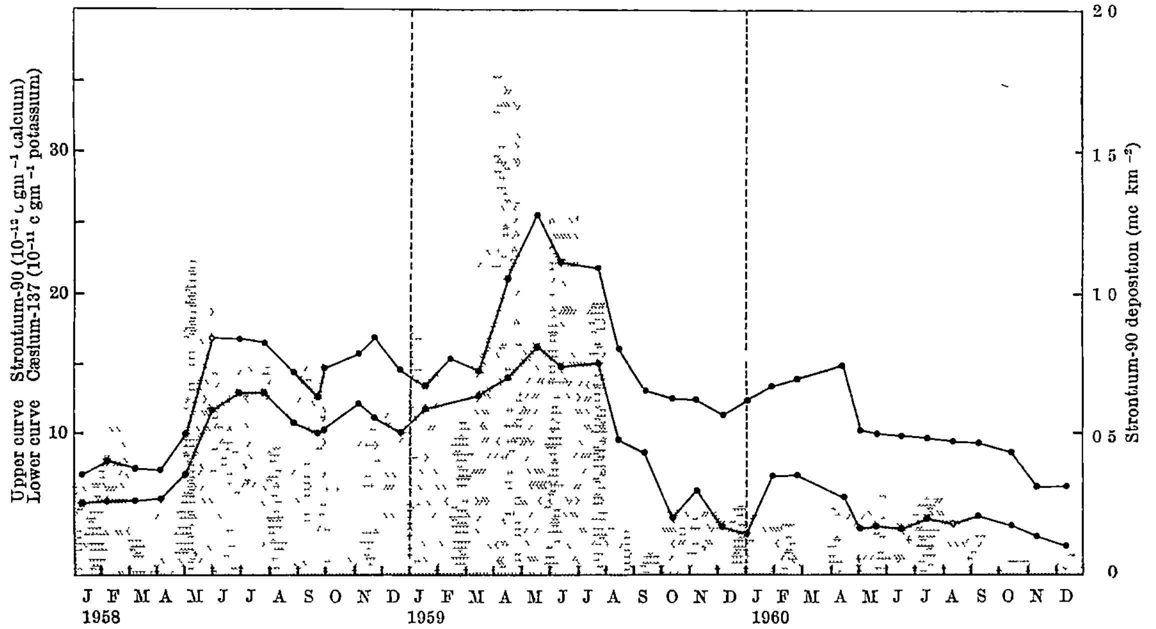

Fig 1 Levels of strontium-90 (upper curve) and cæsium-137 (lower curve) in milk from Felinfach, west Cardiganshire Wales (1958–60) The histogram shows the monthly deposition of strontium-90 in the Felinfach area (ordinate on right)

Table 1. MEAN LEVELS OF STRONTIUM-90 AND CÆSIUM-137 IN FELINFACH MILK DURING SUCCESSIVE MAY–OCTOBER PERIODS (1958–60)

Year	Strontium-90 ($\mu\mu$c /gm calcium)	Cæsium-137 ($\mu\mu$c /gm potassium)	Cæsium-137/ strontium-90 ($\mu\mu$c /L/$\mu\mu$c /l)
1958	15·2	114	10·0
1959	18·5	113	8·1
1960	9·5	36	5·0

inclusively. The results for strontium-90 and cæsium-137 levels in the milk during 1958–60 are presented in Fig. 1, together with a histogram showing the monthly strontium-90 deposition in the Felinfach area. The trend of the monthly cæsium-137 deposition was broadly similar to that shown for strontium-90, with an average cæsium-137/strontium-90 ratio of 1·7.

Looking at the 1960 results (Fig. 1) it will be seen that the levels of both strontium-90 and cæsium-137 in the milk rose during the early months of that year. This reflects the change-over to winter feeding conditions which involved the use of feeding stuffs harvested during a period of relatively high fall-out rate in 1959. When we come to the 1960 open-pasture feeding period (May–October) there is a sharp change to lower steady values. In Table 1 the average level of activity in the milk during the May–October period of 1960 is compared with those for the corresponding periods of 1958 and 1959. It will be seen from Table 1 that the level during the 1960 open-pasture period was markedly lower than those for the two preceding years. A glance at Fig. 1 shows that the trend of the levels of activity for milk was broadly similar in direction to that of the rate of deposition. In contrast, the cumulative total of deposition rose by a factor of 1·75 between mid-1958 and mid-1960 (Table 2). Thus, the view[3] that the sharp increases of activity in the milk during 1958 and 1959 were due chiefly to corresponding rises in fall-out rate, is strongly confirmed.

Table 2. DATA ON STRONTIUM-90 AND CÆSIUM-137 LEVELS IN MILK SAMPLES AND ON RATE OF DEPOSITION AND CUMULATIVE DEPOSITION IN THE FELINFACH AREA DURING 1958–60

	Strontium-90			Cæsium-137		
Month*	Activity in milk (10^{-12} c gm $^{-1}$ calcium)	Rate of deposition (mc km $^{-2}$ mth $^{-1}$)	Cumulative deposition (mc km $^{-2}$)	Activity in milk (10^{-12} c gm $^{-1}$ potassium)	Rate of deposition (mc km $^{-2}$ mth $^{-1}$)	Cumulative deposition (mc. km.$^{-2}$)

* The time unit used in the computation of the rate of deposition was the calendar month. The periods covered by five of the bulked milk samples in their original grouping (refs. 2, 3) (Fig. 1) did not correspond closely to a calendar month. In these cases we have re-grouped the single samples and have made fresh determinations. In two cases, indicated by +, the bulked samples each comprised only two single samples.

A previous interpretation of the strontium-90 level in Felinfach milk samples during 1958 indicated that less than 35 per cent was derived from the reservoir of activity accumulated in the soil[7]. In 1960, with a larger soil reservoir and a much-reduced rate of fall-out, it might be expected that the levels in milk would be determined to a greater extent than before by the soil reservoir activity. This appears to be borne out by the fact that in 1960 the strontium-90 level in milk did not drop in the same degree as did the rate of fall-out (Fig. 1). In comparison, the trend of cæsium-137 levels in milk followed the fall-out trend more closely, indicating that in this case the contribution from the soil reservoir was less important. The demonstration (Table 1) that the cæsium-137/strontium-90 ratio of activities in the milk decreased progressively during 1958–60 is consistent with this interpretation. In the analysis which follows these various relationships are assessed more closely.

Attempts have been made previously[8–10] to establish quantitative relationships between the levels of activity in milk, on one hand, and the rate of deposition and the cumulative deposition, on the other, using equations of the type

$$C = a\,D_p + b\,D_t \qquad (1)$$

where C represents an activity-level in milk, D_p an amount of activity deposited over unit area of ground during a short selected time period (rate of fall-out), D_t the accumulated total of activity deposited over unit area until any given time (cumulative fall-out), and a and b are proportionality factors. These attempts have been hampered by a lack of adequate data and in addition there has been an unfortunate tendency to use yearly average values for the C and D_p parameters. Since yearly average values for C incorporate winter values which reflect in large measure levels of contamination in stored fodder, the meaning of such correlations is often difficult to assess. In the present analysis, we restrict ourselves to consideration of levels of activity in samples which were produced during May–October periods, and we use monthly average values for strontium-90 (10^{-12} c gm $^{-1}$ calcium) and cæsium-137 (10^{-12} c gm $^{-1}$ potassium) activities in milk. Our values for activities in milk are listed in Table 2, together with estimated values for the monthly rates of deposition (mc km $^{-2}$ month^{-1}) and the cumulative totals (mc km $^{-2}$) at each month. The deposition figures have been computed from published information on the strontium-90 and cæsium-137 concentrations in rain-water collected at Milford Haven (50 miles south-west of the Felinfach area[11–13], and recently at Sutton in Surrey[14,15], together with the average of rainfall data from five stations located at different altitudes in the Felinfach area. The cumulative totals listed in Table 2 have been corrected to allow for the radioactive decay occurring in each monthly increment of fall-out between the time of deposition and the time at which the total is recorded. We

Table 3. COMPARISON OF COEFFICIENTS OF CORRELATION FOR VARIOUS REGRESSIONS BETWEEN RATE OF FALL-OUT (COMPUTED IN DIFFERENT WAYS) AND MILK ACTIVITY-LEVEL

Periods* used to compute rate of fall-out		(Pn)	P_0	P_1	P_2	P_0+P_1	$P_0+P_1+P_2$	$P_0+P_1+P_2+P_3$	$P_0+P_1+P_2+P_3+P_4$
Coefficients of correlation based on regression analyses made according to equation (2)	(r_{12})	Strontium-90	0.73	0.91	0.75	0.94	0.95	0.94	0.91
		Cæsium-137	0.74	0.83	0.75	0.91	0.95	0.94	0.90

* P_0 corresponds to the month during which the milk was produced, P_1 to the month immediately preceding milk production, and so on for the other Pn. In the analyses which used combinations of fall-out from different months, the numbers taken to represent the rate of fall-out were the arithmetical averages of the sums of the deposits (mc. km.$^{-2}$) for the months involved.

now consider the information contained in Table 2, according to the methods of correlation analysis[16,17].

In considering the correlation of activity-levels in milk with the average of deposition figures over comparatively short periods of time, it is important to take into account factors which may introduce a lag correlation effect. Earlier reports, showing that strontium-89/strontium-90 ratios for both herbage[1] and milk[7] were smaller than those for rain-water collected during the same month, pointed to some degree of integration of recently deposited activity in the herbage, but in the absence of full knowledge of the role of the cumulative deposit it was not possible to express the extent of this effect in a simple fashion. In the present analysis we approach this problem by examining the degrees of correlation which hold between, on one hand, the activity-levels in milk (X_1) for eighteen open pasture feeding months (Table 2), and on the other, various combinations of the monthly amounts of deposition, which may correspond more or less to an effective rate of fall-out (X_2). These relationships are treated as simple linear regressions according to the equation

$$X_1 = a + b_1X_2 \qquad (2)$$

A preliminary examination of scatter diagrams for the two variables indicated the presence of a similar degree of positive correlation when the X_2 values were represented either by the deposition occurring during the month (P_0) in which the milk was produced, or during the previous month (P_1), or during the second previous month (P_2). When deposition values for months before P_2 were used, there was a significant and progressive decrease in the degree of correlation. This result applied equally to strontium-90 and cæsium-137 data. Various combinations of depositions from two or more months were now used to represent the X_2 values, and correlation coefficients were calculated in several important cases. These coefficients are presented in Table 3. It may be noted first that the degree of correlation obtained using the deposition of the month P_1 was higher than in all other cases for which single monthly depositions were used. Secondly, it may be noted that a significant increase in the degree of correlation occurred when certain combinations of monthly depositions were used, the maximum being obtained with depositions from P_0, P_1 and P_2 grouped together. The correlation result for this latter combination is illustrated in Fig. 2 for strontium-90 and in Fig. 3 for cæsium-137. It appears from the analysis that the rate-dependent component of activity in the milk is largely determined, both in the case of strontium-90 and cæsium-137, by the deposition in the month preceding milk production together with smaller contributions from deposition during the current and second previous months.

We now consider the extent to which the levels of activity for milk may be influenced by the reservoir of activity accumulated in the top of the soil. It appears that both strontium-90 (ref. 1) and cæsium-137 (ref. 18) may be largely held within the top few inches of the soil for comparatively long periods of time. A number of factors[4] may lead to a progressive reduction in the availability of this activity to the herbage, but at the present time the rate at which this process occurs is not well established. For the present purpose we assume that the effective soil reservoir is proportional to the cumulative deposit and we denote the levels at each month (Table 2) by X_3. The effective rate of fall-out (X_2) is taken to be the arithmetic average of the sum of the depositions during the months P_0, P_1 and P_2. Analysis of the data to include the second independent variable requires the use of a multiple regression equation which may take the linear form

$$X_1 = a_{1\cdot 23} + b_{12\cdot 3}X_2 + b_{13\cdot 2}X_3 \qquad (3)$$

Application of this regression equation to the data provides a basis for evaluating the proportionality factors appearing in equation (1).

$$(X_1 = C,\ X_2 = D_p;\ X_3 = D_t,\ b_{12\cdot 3} = a;\ b_{13\cdot 2} = b)$$

Restricting the regression plane to pass through the origin ($a_{1\cdot 23} = 0$), we obtain the following results

$$\text{for strontium-90} \quad C = 15.1\,D_p + 0.28\,D_t \qquad (4)$$

with a standard error of estimate (S) = 1.8×10^{-12} c. gm.$^{-1}$ calcium and coefficient of multiple determination (R^2) = 0.85, and

$$\text{for cæsium-137} \quad C = 84.1\,D_p + 0.36\,D_t \qquad (5)$$

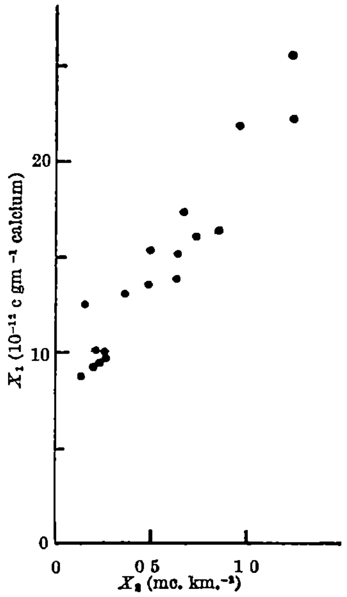

Fig. 2. Correlation chart of rate of strontium-90 fall-out (X_2), taken as average of sum of depositions during months P_0, P_1 and P_2, and monthly strontium-90 level in milk (X_1)

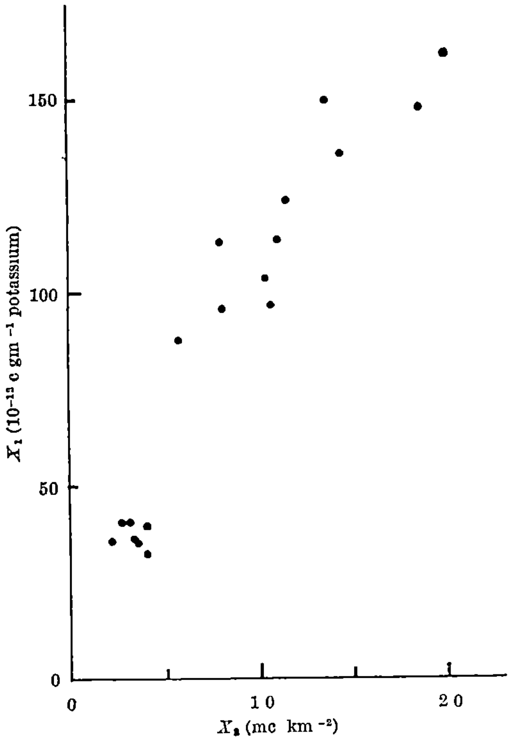

Fig. 3. Correlation chart of rate of cæsium-137 fall-out (X_2), taken as average of sum of depositions during months P_0, P_1 and P_2, and monthly cæsium-137 level in milk (X_1)

with $S = 16·0 \times 10^{-12}$ c gm^{-1} potassium and $R^2 = 0·88$.

The values of the standard errors and the coefficients of determination show that equations (4) and (5) provide a fairly close description of the strontium-90 and cæsium-137 data, respectively, for the open-pasture periods of 1958–60. An application of equation (4) to earlier strontium-90 data also gives estimated levels close to the observed values ((1) October 1957, Felinfach area[6]—observed 9·7 × 10^{-12} c gm^{-1} calcium, estimated 8·1; (2) May–August 1957, pastures at Carmarthen adjoining Felinfach area[19]—average value observed 7·0, estimated 7·8; (3) October 1956, Carmarthen[1]—observed 8·0, estimated 7·5). An evaluation of the rate and cumulative components of the equations suggests that during May–October 1960 the soil reservoir activity accounts for about 70 per cent of strontium-90 in the milk and about 35 per cent of cæsium-137. It may also be noted that the ratio of the proportionality factors in the equation for strontium-90 ($a/b = 54$) is markedly different from that for cæsium-137 ($a/b = 234$). A change in deposition-levels would not therefore be expected to have an equal effect on the level of strontium-90 in milk compared with that of cæsium-137. This provides an explanation of the changes observed in the cæsium 137/strontium-90 ratios for the milk samples produced during 1958–60 (Table 1).

The results of the present analysis apparently provide a useful guide to the degree of contamination which might be expected to arise in milk under a given set of deposition conditions, and at the same time indicate the extent to which this contamination might persist. The results are strictly applicable only to the Felinfach area, but, as noted at the outset, it appears likely that the corresponding relationships for other regions in Britain are broadly similar in magnitude to those shown in equations (4) and (5).

The trend in levels of activity of milk during 1961 will depend partly on the rate of transfer of activity from the stratospheric reservoir to the troposphere, and also on the extent to which direct additions of activity may be made to the troposphere during the new series of weapons tests that was begun in September 1961. Measurements of the concentration of strontium-90 in rain-water collected at our laboratory during the early part of 1961 give values which are about 1·5 times smaller than the corresponding values for 1960. These results, together with the rainfall data available at present, give a preliminary indication that the rate of fall-out during January–August, 1961, will be smaller than that for the corresponding period of the previous year. Consequently, the rate-dependent components of activity in the milk may also be expected to decline. An increase will occur in the cumulative deposition between mid-1960 and mid-1961 but the increment should be less than 5 per cent of the mid-1960 total. Further, this increase may be more than offset by depletion of the effective soil reservoir due to small changes in the distribution of activity within the top layer of the soil. This is suggested by the results reported by Squire[4] of experiments on plants grown in soils treated with strontium-90, where it was found that the availability of the activity to the plants decreased by about 25 per cent over a period of 3 years. The available evidence therefore indicates that a further decrease of activity-levels will be observed in milk produced during the summer and early autumn of 1961.

We thank the Milk Marketing Board for the supply and preparation of the milk samples, and also the Meteorological Office and the Welsh Plant Breeding Station (Aberystwyth) for information on rainfall. Valuable assistance in the chemical analyses was given by Mrs. A. Perry. We are indebted to the director of this Department, Prof. W. V. Mayneord, for his constant support and guidance.

FISH IN NUTRITION

THE Fisheries Division of the U N Food and Agriculture Organization, in collaboration with the Divisions of Nutrition and of Animal Production and Health, were responsible for organizing a conference which, at the invitation of the Government of the United States, and with generous financial assistance from the Division of General Medical Sciences through the agency of the National Academy of Sciences, was held in the new conference auditorium of the Department of State, Washington, D C, during September 19–27 Various North American commercial fish organizations also combined to make the gathering a success

The conference, which was attended by more than three hundred official participants and various experts and industrialists from more than thirty countries, was opened by Dr D B Finn, the director of the Fisheries Division, as representative of the Director-General, after an address of welcome by the Hon Stewart L Udall, Secretary of the Interior There was also a message of greetings from President Kennedy

The chairman of the conference was Mr Donald L McKernan, director of the Bureau of Commercial Fisheries of the Fish and Wildlife Service of the U S Department of the Interior, and five main topics were discussed, each under a distinguished chairman, with a rapporteur and secretary, covering exhaustively the various biological, chemical, technological, nutritional and economic aspects of fish and fish products For each topic a number of review papers, thirty-four in all, had been invited from well-known authorities, supplemented by thirty-five selected original short research papers These were all circulated beforehand, the latter as abstracts only, and contributors briefly introduced their papers The edited proceedings, including the various recommendations and conclusions, are to be published by Arthur J Heighway Publications, Ltd , 110 Fleet Street, London, by arrangement with the Food and Agriculture Organization, next year

As it is impossible in the course of a short article to cover adequately such a broad and detailed agenda, a personal selection has had to be made of the various important issues that were discussed by the numerous experts present

Productivity of the Seas

There was a clash of opinion among the marine biologists on the maximum harvest that could be expected from the seas Some took the conservative view that knowing the quantity of solar energy that can be fixed by marine plants and making certain assumptions as to the number and efficiency of the conversion steps in the food chain, one cannot hope for much more than double, or at most treble, the present catch of slightly less than thirty million tons of marine fin fishes per annum Others pointed out that landings from the oceans have already nearly doubled in the past ten years, and thought that there was reason for believing that, even using present methods of fishing, five or even ten times the present yield could be achieved and sustained

At present commercial fishing operations are largely determined by market considerations Many edible species, such as sharks, are often not brought home even when caught A two million ton per annum fishery of anchovies used for fish meal has sprung up off the coast of Peru in less than a decade Some American biologists believe that a similar potential exists off the coast of California, and that there are also untapped resources of saury, which would be despised as a food fish in the United States although since the War it has been canned on a large scale in Japan Improved methods of preventing decomposition, such as freezing at sea, is enabling Russian and Japanese ships, for example, to exploit fishing grounds all over the world

Again, greatly improved methods of fishing can be envisaged In spite of much effort on the part of the Food and Agriculture Organization and Governments, there is still a several hundred-fold difference between the highest and lowest productivity per fisherman The suggestion was revived of a planned ploughing of the sea through the convectional effect of nuclear reactors, by means of which nutrient-rich ocean depths could be brought into the life-cycle of the upper layers Finally, also looking well into the future, there is the prospect of fish farming on a scale as yet unimaginable, perhaps involving the intelligent utilization of the organic material at present prodigally wasted in sewage

However, these distant vistas do not dispose of the fact that here and now in certain more easily accessible areas there is a decided falling off in yield due to uncontrolled fishing, with uneconomic results The future yield in such cases is not determined only by Nature, but depends in large measure on the decisions of man himself Man acts not only as a predator and disturber, but also as an intervener in natural systems, so that the fish stock of the future, in the words of Dr G L Kesteven (Cronulla, New South Wales), "is likely to be so much more or less than it is now, as man makes it to be"

It therefore seems that, although there is no justification for pessimism, more work will be needed before the basis exists for even an approximate estimate of the potential yield of the oceans

Unequal Distribution of Fish Supplies

Added to the uneven development of the present world fish catch is the inequality of its distribution In this respect there is a general lack of realization of the implications of the tremendous gap that exists between the 'have' and 'have-not' nations

Although the world dietary deficit in calories is relatively slight, so that probably relatively little actual starvation occurs, there is a general protein under-nourishment over much of the globe which greater consumption of fish could do much to remedy Even where national statistics which are reliable indicate adequate average diets, deficiencies are known to exist in special regional or socio-economic groups Children in the age group 1–4 years have special protein needs but often do not receive a proper share of the right foods Kwashiorkor and marasmus are protein-deficiency conditions of infancy which cause many fatalities, particularly in Africa and South America Women frequently pregnant and lactating equally require high animal protein intake, but all too often men get priority Protein under-nourishment, even where not fatal, is responsible for untold misery, debility, disease, and retarded growth and development.

Although fish accounts for only about 12 per cent of the total animal protein available, it nourishes far more than this percentage of the world population. For more than 1,000 million people it constitutes the chief source of animal protein. Milk and meat products, although bulking much larger, feed far fewer millions. Fish is the protein of the poor, nationally and globally.

Over North America and most of Western Europe the consumption of other animal products is so much greater than that of fish that the latter could practically disappear altogether from the diet without being missed. However, fish is equally nourishing for farm animals, the requirements of which have received much closer examination than those of human beings. The high and increasing output of meat products in the West is facilitated by converting about 5 million tons of edible fish annually into feeding meal for animals. Only a small proportion of this fish meal comes from recovery of industrial waste. The bulk is from whole, edible fish caught entirely for reduction, much of it in Africa and South America. 95 per cent of this trade goes to produce milk, bacon and eggs in the countries least requiring extra nutrition. For example, one third of the broiler production in the United States can be attributed to the sea.

One of the topics which received greatest attention at the conference was the part that the polyunsaturated fatty acids of fish oil could play in the prevention of obesity and coronary and cerebral thrombosis, associated with excessive meat consumption, which are now among the major killers in the 'over-developed' nations (as they were termed). It is a grim irony that a contributory factor to such 'over-nourishment' (itself a special form of malnutrition) is the fish protein concentrate drawn from the very continents where protein under-nourishment is so rife.

But quantities that are essentially only of marginal interest to the West represent the difference between health and disease for many millions of people on the verge of starvation. Thus, if the enormous fish production of Peru, at present exported as fish meal, were consumed in South America instead, it could raise the nutritional status of that continent to the level of that of Italy.

The inequitable distribution of fish protein resources is further flaunted in the 300,000 tons of raw fish used yearly to produce fur on the mink farms of the United States and Scandinavia for a form of apparel used not so much for the warmth as the adornment of the wealthy. To quote the report issued at the end of the conference: "It is clear that 400 million people cannot continue to get the overwhelming part of the world's animal protein, while 2,500 millions are neglected and deprived of this essential nutrient". The situation is made even more acute by the expected doubling of the world's population to 6,000 millions in the next 40–50 years.

Utilization of Fish

Great disparities also emerged in considering the efficiency of utilization of fish as food for man and beast.

There was a general consensus of opinion that fish is a first-class food, rich in high-quality protein, valuable lipids and most of the fat- and water-soluble vitamins and minerals. However, there are appreciable losses of nutrient in handling, processing and storage which, in extreme cases, can amount to a sheer wastage of as much as three-quarters of the substance of the fish before it is consumed. Wastage occurs in trimming raw fish, by which much of the edible flesh is left on the bone, to the benefit of fish meal again. Protein and water-soluble vitamins escape during salting, and both can suffer as much as 50 per cent loss of quality during severe drying processes. Over much of the world insects cause further loss, as much as 50 per cent being reported from Nigeria.

Furthermore, there is, even in well-developed countries, the imponderable consideration of the effect on fish consumption of loss of palatability on account of chronically careless handling of a very perishable commodity between catching and consumption.

Although there is much more that could be found out by further research, it is not lack of knowledge that is holding up technical advance so much as the lack of application of established knowledge and experience. In many cases the formulation and adoption of suitable standards of processing the product are seen as a means of providing the impetus for technical improvements.

There was a difference of opinion about the toxicity of oxidized fish oils, attributed to the extreme reactivity of hydroperoxides. Such oxidation, associated with many traditionally cured products, is also partly responsible for their characteristic flavour, which is often greatly relished in a cereal diet in circumstances where fish is regarded more as a condiment than as a source of protein.

Refrigeration and canning, which are serviceable stock methods of preservation under a wide variety of conditions, result in little or no loss nutritionally.

There did not seem to be much hope that any of the newer methods of preservation, however satisfactory nutritionally, could be expected to assume such importance that proper care and control over established processes would soon be unnecessary. Vacuum freeze-drying of fish seemed unlikely to compete in quality with freezing in the West, or in cheapness with the traditional methods used elsewhere. The possibilities of sterilization by radiation, too, seem to have been greatly over-rated. On the other hand, the recent development of a large Japanese industry for manufacture of fish sausage was noted with interest, and thought to be a means of extending the outlet for fish in many other areas. Consideration would, however, have to be given to the advisability of encouraging the use of the chemical preservatives permitted in Japan.

Much discussion centred around the possibility of producing a tasteless fish flour that could be introduced particularly into the diets of young children in needy areas. The technical difficulties and achievements to date were reviewed and standards proposed for products of acceptable quality and nutritive properties. While some saw in fish flour "the basic fishery product of the future", others felt that much more could be done here and now to improve nutrition by means of the application of knowledge and experience already available for types of fishery product known to be generally acceptable.

Economic and Educational Problems

Without denying the need for immediate emergency schemes for using fish as nourishment, other animals are not necessarily competitors with man for the fish supplies A good case can be made out for the use of fish for animal feeding as part of a planned protein economy, although at present this is of more interest to the West than to the rest of the world Much vegetable protein, in the form of grass, for example, is made available to us because cattle diets are supplemented with a small amount of fish meal Although there is a loss of energy at each step in the food-cycle, protein may be converted with 50 per cent efficiency in ideal circumstances Essential amino-acids such as lysine and methionine may be recovered at efficiency-levels up to 70 per cent in animal products such as hen's eggs Ruminants, particularly, can make better use of fish products regarded as of low quality for other purposes

However, it was admitted that animal feeding is a very opportunist operation, which makes use of whatever products and by-products are available at suitable prices If the fish at present used for fish meal were to be upgraded to, say, fish flour, for human use, the industry would be forced once again to look for alternative sources of supply and would have to rely on industrial fish waste and such feeds as soya bean meal supplemented with synthetic amino-acids, although at somewhat higher cost

In the world of commerce it is more profitable to make fish meal or raise mink than it is to make and distribute food for children of low-income groups However, there are circumstances in which nations cannot afford to count the cost, and a concerted attack on freeing the world from hunger is surely a worthy cause The Food and Agriculture Organization has, in fact, initiated such a campaign which it is the duty of the more fortunate nations to support to their utmost However, even if economics were over-ridden in some such manner, there are technological and educational problems to tackle in getting fish consumed where it is needed It is true that this is only one aspect of accelerating a general expansion in production and standard of living in under-developed countries But more organized technical assistance needs to be given before many countries are in a position fully to help themselves The Organization needs further support in making their self-help more effective Training of personnel at all levels should have greater priority Fishermen and others have to be taught to use better methods of catching and preservation Consumers need education in the development of better dietary habits Technical personnel, research workers and administrators all need training before programmes of fisheries expansion can be implemented

Obviously this cannot be done overnight However, it was felt by many at the conference that more effort should be put into education by providing expanded facilities for technicians to be trained to understand and utilize improved methods based on present knowledge and experience

Finally, there was considerable support for the thesis that, although admitting that much of what is already known is not being made use of, increased support for fundamental research is essential for the most efficient utilization of fish in the future

C L Cutting

THE INTERGOVERNMENTAL OCEANOGRAPHIC COMMISSION

THE oceans, which cover some 70 per cent of the surface of the Earth, are perhaps one of the greatest fields for scientific investigation They contain unlimited areas of study in practically every scientific discipline and yet, measured with the yardstick of our knowledge of the Earth and the atmosphere, it must be admitted that we have to learn much more about the sea before we can hope to understand its vagaries and make full use of its resources

We know enough about it to appreciate the complexity and vastness of the problems which confront us, and there can be no doubt that many of them can only be solved when scientists co-operate on an international scale Although one is apprehensive in condoning the establishment of more international organizations labelled with forbidding combinations of the alphabet, there is no doubt that the establishment of the Intergovernmental Oceanographic Commission (I O C), which held its first meeting in Paris during October 19–27, fulfils a long-felt need and promises better co-ordination in the future for marine science

International organizations dealing with the science of the sea have existed for many years, but they have been either of a regional nature or confined to a limited scientific field In 1957 the International Council of Scientific Unions foresaw the necessity for a wider scale of co-ordination of activity, both geographically and disciplinary, and it established a Special Committee on Oceanic Research (S C O R) to consider such problems The activities of the Committee are, however, primarily scientific, and although, as one of its projects, it has initiated an international expedition to the Indian Ocean, it still remains a non-governmental organization solely dependent on co-operation with national academies or similar scientific organizations

The Intergovernmental Oceanographic Commission, on the other hand, now makes possible a direct approach to participating governments and forms a very necessary link where projects involving considerable expenditure are contemplated At its first meeting, Dr Anton Brunn, of Denmark, a leading biological oceanographer, was elected chairman. Dr William M Cameron, director of oceanographic research for the Canadian Department of Mines and Technical Surveys, and Vice-Admiral V A Tchekourov, head of the Hydrographic Service at Leningrad, were elected as vice-chairmen The Commission appointed as its secretary Dr Warren Wooster, director of the Unesco Office of Oceanography, which will act as secretariat

The initial task of the new body was to define its own responsibilities and the manner in which it would function, particularly in relation to existing organizations The decisions reached show that it is prepared not only to receive the advice of existing inter-governmental and non-governmental organizations which at present advise Unesco on oceanographical matters, but also the hope was expressed that the Food and Agriculture Organization, the World Meteorological Organization and other specialized agencies of the United Nations would co-operate actively with the secretariat of the Commission.

Numerous proposals for joint international oceanographic programmes were made by member States and a list of these was selected for particular consideration Many of the proposals amounted to regional surveys of interesting and important parts of the ocean, but it is also encouraging to note that some novel ideas were put forward The proposal from the United States for a synoptic survey of the North Atlantic Ocean emphasizes a long-felt need in oceanography, which could only be accomplished by the ships of several nations working together Some proposals by the U S S R included plans for studying the time changes in physical characteristics of the oceans, while others were aimed at the study of limited fields of currents which might be expected to yield more information about the mechanism of the processes occurring in the sea Such fundamental studies are an essential corollary to survey work if any real understanding of water movements is ever to be reached

An awareness of the difficulties facing large co-operative programmes was shown by a resolution submitted by the French delegation, who noted with concern the present shortage of experts in the marine sciences This shortage could well delay the whole development of marine science for many years to come, and it was proposed that an urgent appeal should be made to Governments to create the necessary permanent posts and assured careers for young scientists and technicians who are attracted by the marine sciences

Another barrier to advancement noted by one of the working groups set up by the Commission was the present lack of standardization and intercalibration of oceanographical methods and equipment With a number of nations participating in co-operative programmes, the necessity for more standardization and intercalibration becomes more urgent and the Commission has requested the Special Committee on Oceanic Research to appoint working groups of scientists qualified in the specialized fields to examine the present methods and make recommendations about the appropriate steps necessary to make them universally effective

In its planning for the International Indian Ocean Expedition, the Special Committee on Oceanic Research has already commenced this task Scientists from different countries have already met together to intercalibrate methods of measuring primary organic production, nutrient chemical analysis and zooplankton sampling methods Agreement has been reached on a standard plankton net for use on the Indian Ocean Expedition

The question of the co-ordination of activities in the International Indian Ocean Expedition was also the subject of discussion, and it was felt that although this had been most satisfactorily and energetically carried out by the Special Committee on Oceanic Research and its co-ordinator, Mr R G Snider, in New York, the responsibilities of that body were primarily scientific, and the co-ordination of the participating nations in such expeditions should more rightly lie with the Intergovernmental Oceanographic Commission and its secretariat The question whether the latter should take over these activities for the Indian Ocean Expedition was considered by the Special Committee on Oceanic Research at its meeting in Monaco, following the meeting of the Commission While appreciative of the principle, the Committee considered that it would be a slow and complicated task to divide and transfer the co-ordination, but a mechanism was set up to take advantage of the new possibilities

A further subject of discussion was a proposal for an international oceanographic research and training vessel to be sponsored by Unesco While sea-training is essential, opinion was very divided on the practicability of operating such a vessel In view of existing facilities for international exchange of scientists between national vessels, it was felt that there is no really outstanding need for a jointly owned ship, but that the idea should be kept in mind for consideration at some future date

To assist in the urgent question of accurate positioning at sea, the working groups recommended close co-operation with the International Hydrographic Bureau and the International Civil Aviation Organization to see what can be done to expedite the development and establishment of navigational systems which will meet the requirements of detailed oceanographical investigations (for example, an accuracy requirement of ± 0 25 nautical mile)

The intended use of unmanned equipment in the study of the sea also raises a problem of communication and telemetering information from remote parts of the ocean Existing frequencies in radio communications are rapidly becoming absorbed and the bureau of the Commission has been authorized to specify requirements which can be put to the next meeting of the Administrative Radio Conference

Perhaps the one outcome of the meeting of the new Commission of most immediate interest to practising oceanographers will be suggested improvements in disseminating information Not only should these improve the exchange of data, but also publicize plans of projected cruises with information on the facilities available to visiting scientists Such information will be circulated in a newsletter from the Unesco Office of Oceanography

Although a good deal of the meeting of the Intergovernmental Oceanographic Commission was occupied with putting its own house in order, it is clear that action has been initiated in a number of urgent problems The Commission is in a position to place the needs of marine science before the Governments of member countries and will no doubt adopt a balanced attitude to the various disciplines involved In this respect, the biologists attending the meeting felt some degree of apprehension as their own subject, although extensively studied, is ill-co-ordinated at an international level After an informal discussion, they concluded that to ensure that the Commission should receive the best scientific advice concerning biological phenomena in the sea, it would be of the greatest importance to set up a forum which can give the proper international backing to biological oceanography and they have undertaken, with the approval of the Special Committee on Oceanic Research, to work for the formation of an International Association of Biological Oceanography.

Towards the conclusion of the meeting of the Intergovernmental Oceanographic Commission, a session was devoted to the memory of one of the greatest oceanographers, Dr Fritjof Nansen, on the occasion of the centenary of his birth on October 10, 1861 A most eloquent tribute was paid by Prof A D Dobrovol'skiy, who described many of Nansen's achievements in oceanography and exploration Dr G Bohnecke spoke of his personal memories of Nansen, and Prof H Mosby concluded the session by showing some of Nansen's own lantern slides

RONALD I CURRIE

CHEMISTRY IN THE SERVICE OF MEDICINE

THE second British Congress on the History of Medicine and Pharmacy, organized by the Faculty of History of the Worshipful Society of Apothecaries of London in co-operation with the Chemical Society and sponsored by Glaxo Laboratories, Ltd., was held in London during September 27–29.

Prof. D. McKie, who occupies the chair of the history and philosophy of science at University College, London, was president of the congress, which had as its theme "Chemistry in the Service of Medicine". The twelve papers given provided an authoritative historical review of the services which chemistry has rendered to the development of medicine from the sixteenth century to the present day.

The inaugural session was held at Apothecaries' Hall on September 28, when Dr. A. G. Debus (Harvard University and University of Chicago) opened the proceedings with an account of Paracelsian doctrine in English medicine up to 1660. Prior to that date chemical methods and terminology were widely used in England on practical and theoretical levels. Chemical remedies and analysis did not originate with Paracelsus but were closely associated with the work of the iatrochemists. The impact of chemistry can be discerned in Paracelsian views on the origin of matter and in premature attempts to explain life processes in chemical terms. Theory was less popular in England than practice, but the present close bond between chemistry and medicine can be traced to the Paracelsian and Helmontian iatrochemists of the sixteenth and seventeenth centuries.

Dr. F. W. Gibbs (Royal Institute of Chemistry) emphasized the importance of Herman Boerhaave (1668–1738) who impressed a new, scientific, pattern on medical theory and practice in which chemistry had a central position. His *Elementae Chemiae* (1732) is a classic, the first volume being largely physical in outlook while the second is devoted to physiological, biochemical and clinical applications. The characteristics of his method were described with the aid of examples taken from his work on heat, pretended alkaline cures for gout and the stone, fermentation processes, and body fluids.

Prof. D. McKie spoke on "Chemistry in the Service of Medicine, 1600–1800" and described some of the many text-books of medical chemistry which appeared in that period. Notable among these was the *Cours de Chymie* of Nicholas Lemery, which appeared in many editions between 1657 and 1757. Boerhaave's work had transformed chemistry into an academic science *per se* and rid it of its pharmaceutical bias. The next line of progress was exemplified by Van Helmont's work on 'gas', the experiments of Boyle on combustion and respiration, and the remarkable theories of Hooke and Mayow, the influence of which was deferred by the rise of the phlogiston theory. With Black's discovery of 'fixed air' as an 'air' chemically distinct from common air, and with similar studies by Cavendish, Priestley and Scheele, this problem approached solution with the work of Lavoisier, whose discovery of the compositions of air and water, together with his calorimetric studies on respiration, opened the way to physiology.

The afternoon session at the Royal College of Physicians, with Dr. Charles Newman in the chair, was opened by Prof. F. G. Young (Department of Biochemistry, University of Cambridge), who traced the rise of biochemistry between 1800 and 1900. The idea that the chemical processes in living materials were subject to laws different from those applicable to the inorganic world lingered until almost mid-century. By the time it was largely rejected, the term 'organic chemistry' began to lose its original connotations and to be applied to synthetic compounds of carbons whether or not such substances had originally been derived from living matter. The controversies about fermentation and decomposition between Liebig and others, who included Schwann and Pasteur, were gradually decided in terms of the existence of intracellular enzymes. Ehrlich's early investigation on intracellular utilization of oxygen emphasized the role of activation of oxygen in the tissues for purposes of cellular combustion. The reasons why British chemists so largely ignored the possibility of applying their science to biology in general, and to animal metabolism in particular, are obscure, but may be found in the love of household pets (with dislike of animal experiments), the dominance of mathematical studies in British scientific education, and the controversies which followed the publication of *The Origin of Species*.

Speaking on the early history of pharmacology, Prof. W. D. M. Paton (Department of Pharmacology, University of Oxford) began by comparing the knowledge of drugs at the beginning of the nineteenth century, as shown in J. A. Paris's *Pharmacologia*, with that in Binz's *Lectures in Pharmacology* at the end. The main difference lay only in the general scientific background, although some important new drugs had been found in the intervening period the real revolution in therapeutics had scarcely begun. There was some exemplary work on the analysis of drug action and in structure/action relationships, but there was no consistent impetus or drive. When, therefore, did experimental pharmacology really get under way and what period could be defined as its 'early history'? Prof. Paton sought to answer this by studying the rate of change in the pharmacopœias, by tracing the rise and fall of different types of preparation and the introduction of substances pure enough to inject, by following the development of new 'unnatural' chemical structures, and by charting the rate of establishment of fully fledged departments of experimental pharmacology. All this type of evidence indicated that pharmacology was only now reaching maturity and that the main contribution which it would make to medicine, as well as to general biological science, was still to come.

Dr. W. D. Foster, of Dudley Road Hospital, Birmingham, and formerly of St. Thomas's Hospital, London, spoke on chemical pathology, which began as an extension of two ancient diagnostic procedures uroscopy and the inspection of blood shed at therapeutic phlebotomy. Between about 1680 and 1740, men such as T. Willis, J. Locke, R. Boyle and B. Langrish conceived that useful diagnostic information might be obtained by chemical analysis as well as inspection of blood and urine, but because of the limitations of chemistry obtained no useful results. A simpler approach to blood analysis in which the weight of fibrin, red cell mass, serum protein and water was determined, enabled Andral, in the 1840's, to establish that disease might produce chemical changes in the blood The first really useful diagnostic test in chemical pathology was for the detection of albuminuria and was introduced largely through the work of three British physicians, W C Wells, J Blackall and R Bright, in the early nineteenth century.

The modern development of chemical pathology began during the first decade of the twentieth century, and depended on the introduction of venepuncture to obtain adequate blood samples and the development of colorimetric analysis which was both sufficiently sensitive and simple enough for clinical purposes

At the third session, held at the Royal College of Surgeons on Friday morning, the help given by chemistry to the elucidation of certain important medical problems was discussed Sir Charles Dodds traced the growth of endocrinology and of organic chemistry, the former from Addison's great work on the suprarenal capsules (1855) and Claude Bernard's work on glycogen, followed by Oliver and Schafer's experiments with an extract of the suprarenals in 1895, the latter beginning with Wohler in 1828 and taking a great leap forward to synthetic organic chemistry with the contributions of Kekulé, Cooper, Van't Hoff and Le Bel The synthesis of adrenaline was the first milestone, the second was the synthesis of thyroxine by Barger and Harington (1926), following its isolation by Kendall (1916) and the clinical work on myxœdema by Murray in 1891 In a remarkable diagram Prof Dodds showed all the chemical activity which has stemmed from Addison's paper in 1855 Among the substances isolated and characterized from the suprarenals, and yet others derived from these substances, are ascorbic acid, adrenaline and the sympathome drugs (for example, amphetamine), œstradiol and its analogue stilbœstrol, cortisol and the derivatives triamcinolone and prednisolone, aldosterone and its derivatives, progesterone and analogous compounds, testosterone and the anabolic steroids, and, finally, noradrenaline and the whole group of antihistaminic drugs which stem from it The stimulus for it all came from medicine and biology, and particularly from endocrinology

Chemistry and cancer was the theme of the paper by Prof Alexander Haddow, who discussed the role of chemical substances in cancer pathology and therapeutics In 1775 Percival Pott had written a classic account of cancer of the scrotum in chimney-sweeps which definitely incriminated soot as the causative agent During the industrial revolution, coal-tar, mineral-oil and pitch were added to soot as materials capable of causing a great deal of industrial and environmental cancer, as exemplified in Joseph Bell's description of skin cancer among workers in the Scottish shale-oil industry The term 'carcinogen' was first used in 1853 by Sir James Paget, who cited Lebert (1851) as proposing that a chemist must aid the pathologist in research on cancer After many attempts, experimental cancer was produced artificially by coal-tar by Yagamura (1915) and during 1921–26 Block showed that cyclic hydrocarbon was the active carcinogen At about the same time the work of Cook and Kennaway vindicated Lebert's forecast and provided, using artificial tars, virtual proof of the carcinogen hypothesis, which was further extended by the implication of 3 4 benzpyrene, certain biological alkylating agents and other substances It was stressed that there was no antithesis between the study of viruses and chemical carcinogens, for chemistry was essential to both Chemotherapy, which had begun with Lissauer and the use of arsenic in the treatment of leukæmia, was already developing rapidly, as shown by the use of stilbœstrol in breast cancer and of other useful products such as myleran

Dr T F Macrae, speaking on chemistry and nutrition, said that in the development of improved nutritional standards, especially in the past thirty years, chemistry has played a major part Increases in crop yields have largely been due to synthetic fertilizers, adequate supplies of which have been ensured by the early discovery of nitrogen fixation More recently further advances have accrued from the wide range of pesticides now available

In the field of nutritional deficiencies the work of chemists on vitamins has been particularly beneficial All the important vitamins are now available synthetically at costs far lower than from natural sources Indeed, in advanced countries at least, vitamin deficiencies are no longer encountered. Similar developments are likely with the amino-acids, it now being a simple matter analytically to determine the adequacy or otherwise of a protein source Already in animal nutrition it has in some instances proved more economic to provide part of the nutritional requirements in synthetic form.

There still remains, however, the problem of inadequate nutrition, especially of protein, in the under-developed countries This is in part technological since, though we can identify the deficiency and, in chemical terms, propose the remedy, we still have to find sufficiently cheap means of providing this remedy in a form acceptable to the populations concerned

In the final session, held at the Chemical Society's rooms with Sir Robert Robinson in the chair, Prof D Catcheside reviewed the relationship between chemistry and genetics, beginning with the rediscovery of Mendel's work in 1900 and the speculation about the nature of his 'elements' Chemical knowledge of their action is more advanced than that of the genes themselves It began with the study of the differences between phenotypes determined by single Mendelian differences, such as the flower pigments of snapdragons by Muriel Wheldale (Onslow) This showed that a gene controlled the onset of a specific chemical reaction But the conception of a gene-enzyme-chemical reaction system was due to Garrod's work on alcaptonuria and other inborn errors of metabolism in man He considered that the abnormal gene resulted in absence or inactivity of the enzyme that normally cleaves homogentisic acid, in turn giving rise to disordered metabolism and disease The theory was revived by Beadle and Tatum, following work on the eye pigments of *Drosophila*, when they reversed the procedure by searching in *Neurospora* for gene mutations that influence known chemical reactions This has led, with the aid of the analytical techniques of Pauling, Sanger and Ingram, to the demonstration of specific amino-acid substitutions in abnormal hæmoglobins, and, with the development of microbial genetics, to attempts to correlate genetical and chemical detail for several proteins in fungi, bacteria and bacteriophage As regards the genes themselves, geneticists in the first place showed that they were in the chromosomes, but direct implication of deoxyribonucleic acid, knowledge of the chemistry of which is a recent event due to Wilkins, Watson and Crick, resulted from microbial genetics First, the demonstration that deoxyribonucleic acid is the sole substance concerned in transformation of *Pneumo-*

coccus (Avery *et al.*), and then that it is the vehicle of heredity in bacteriophage (Hershey *et al.*). More recently, attention has been directed to the coding problem and to the mechanism of transfer of specific information from deoxyribonucleic acid to protein.

A survey of progress "from antisepsis to antibiotics" was offered by Dr. W. A. R. Thomson, who said that although antiseptics had a long history, the antiseptic principle was first established by Lister in 1867, an event which led to a long and successful search for bactericidal drugs. Landmarks in that search were Ehrlich's '606', demonstrating the possibility of treatment by specific drugs, the introduction of the sulphonamides and, third, of the antibiotics. The usefulness of the sulphonamides had not yet been fully exploited and 'the antibiotic rush' of the fifties may in retrospect be seen as fundamentally unscientific. The isolation of 6-aminopenicillanic acid in 1959 marked the opening of a new and genuinely scientific era in antibiotic research. Dr. Thomson concluded with a word of caution; indiscriminate use of antibiotics had upset the balance of Nature and "the mass-murder of micro-organisms" was not necessarily a good thing. The careful use of antibiotics combined with immunotherapy offered a wiser course for the future.

Dr. F. L. Rose took one of the important developments of the same period for closer investigation in his account of the origin and rise of the synthetic drugs. With one or two exceptions, he said, all the medicaments available until the mid-nineteenth century were natural products. At that point in time, the coincidental discovery of the first synthetic dyestuffs and of micro-organismal origin of infectious diseases soon brought about a rapid change. The former because it caused an almost explosive growth of synthetic organic chemistry in a way which invited its direction into biological pathways, and the latter because it provided the motive and means for examining the effect on disease of the compounds poured out by the chemists. Thus the evolution of the modern antimalarial agents can be traced back directly to the observed staining of the malaria parasite by methylene blue. Methylene blue is a derivative of phenothiazine, itself widely used as an anthelmintic, and from which stem some of the most effective tranquillizing agents. Similarly, the modern trypanocides owe their beginning to the feeble therapeutic action shown by the early direct cotton dyestuffs, and the medicinal properties, initially antiseptic but later trypanocidal, found in the first azine and cyanine dyestuffs. Likewise, the appearance of the first azosulphonamide drug coincided with interest in the use of the sulphonamide group as a component of azo dyestuffs. These drugs were additionally important in that their technical development directed attention to the sulphones, now widely used in leprosy, while minor side effects were exploited to produce highly effective diuretic and hyperglycæmic agents.

A dinner was held in Apothecaries' Hall when the guest of honour was Sir Howard Florey, and the president of the Chemical Society, Sir Alexander Todd, gave the after-dinner address. He discussed the long-standing relationship between chemistry and medicine and stressed that the indebtedness was mutual, for medicine and its needs had provided a very great impetus to the growth of chemical research. He found in the title of the congress a reflexion of the orthodox separation of the basic sciences, a situation which was probably incapable of fruitful development. Many important problems required workers with many kinds of scientific skill, and although research institutes may provide this kind of team, research was still best undertaken by the universities. The barriers between departments must be broken down to enable the constant influx of young minds to cross the barriers between the sciences.

The papers given at the congress are to be published in volume form. It has already been decided that the meeting next year will be held in London during September 27–28, and will have as its theme "The History of British Hospitals". F. N. L. POYNTER

THE AUSTRALIAN NATIONAL RADIO ASTRONOMY OBSERVATORY

AUSTRALIA made an early start in radio astronomy at the end of the Second World War, and has remained ever since among the leading countries in this rapidly advancing field. Australian radio astronomers now possess a radio telescope which is the foremost of its type in the world at the present time—a 210-ft. steerable paraboloid, with a surface accuracy of a few millimetres.

The new telescope, which is located at Parkes, New South Wales, 230 miles west of Sydney, was commissioned on October 31 by the Governor-General of the Commonwealth of Australia, His Excellency the Right Hon. Viscount De L'Isle, and it will be operated by the Division of Radiophysics of the Australian Commonwealth Scientific and Industrial Research Organization. The telescope is the first instrument of the Australian National Radio Astronomy Observatory, which was inaugurated at the same time.

The plan for a large steerable paraboloid originated seven years ago, when the first specifications were drawn up by Dr. E. G. Bowen, Chief of the Organization's Division of Radiophysics. His vision and enthusiasm have been largely responsible for the successful completion of the project.

A large donation from the Carnegie Corporation (250,000 dollars) enabled the design work to start, and other generous donations were afterwards received from the Rockefeller Foundation (357,000 dollars), and from a number of private donors in Australia. These sums were matched on a pound-for-pound basis by the Australian Commonwealth Government. The total cost of the project has been about £800,000 (Australian) equivalent to £640,000 (sterling).

The novel design was produced by Freeman, Fox and Partners, consulting engineers, of London, with Mr. Gilbert Roberts in charge of the responsible group. The construction was carried out by Maschinenfabrik Augsburg-Nürnberg, A.G., of West Germany, which submitted the best tender, both in price and delivery time, and was awarded the prime contract. The principal sub-contractors were Askania Werke, of West Berlin, Associated Electrical Industries, Ltd., of Manchester, and Concrete Constructions Pty. Ltd., of Sydney.

The telescope is mounted in azimuth-altitude style, on a single concrete tower, which also contains the telescope controls and the radio receivers. The whole structure rotates in azimuth on a circular track which is set into the top of the concrete tower; a range of 450° is available, limited only by the cable-twisting requirements. The altitude motion, between zenith angle 0° and 60°, is obtained through a large rack gear. A wide range of speeds is available in each co-ordinate.

A unique feature of the instrument is the control system for driving the telescope in equatorial co-ordinates. The heart of this system is a small 'master equatorial' unit, which is mounted at the intersection of the altitude and azimuth axes, on a special concrete support, completely isolated from the rest of the structure. This unit controls the motion of the telescope through a servo system which contains an optical link.

The 'dish' is supported by a structure of 30 radial trusses, which carry a system of ring girders and two sets of intersecting spiral members. The reflecting surface consists of wire mesh, with wires 1 cm. apart, except for the inner 54 ft., which is covered with steel plates. The inner solid section was adjusted to fine limits during construction; but the individual panels of the mesh surface carry screw adjustments, which can be reset at any stage.

The aerial feeds and pre-amplifiers are supported by a large cabin, which is mounted on a tripod above the reflector. The cabin is large enough to carry test equipment and observing personnel during special tests, though normal operations will of course be controlled from below. There are a lift in one tripod leg and ladders in the other two, for access to the focus cabin.

The telescope is now structurally complete, and is at present undergoing a rigorous series of tests, through theodolite surveys of the shape of the dish and radio observations of cosmic sources. Some progress performance figures are now available, and very satisfactory results are being obtained.

The original specification called for a surface accuracy of ± 9 mm. With the dish looking vertically, most of the adjustment points on the mesh surface are within 2 mm. of the required parabolic shape—with additional deviations of the same order inside the individual panels.

Some early figures have been obtained for the radio performance at wave-lengths of 21 and 10 cm. At 21 cm., the beam-width is 13½ min. of arc or less, and the side-lobe level is in the region of − 25 db. At 10 cm., the first measurement gave a beam-width of 7½ min., and the side-lobe level is again very low. Moreover, these figures were obtained with the dish 40°–60° from the zenith, where any distortions would be at their maximum.

On the opening day, there was a widely representative gathering of nearly 500 guests at the Observatory, many of whom had come from Sydney, Canberra and Melbourne in a special airlift. Before the ceremony, the visitors inspected the structure, and then were shown a large photographic and descriptive display which had been specially set up for the occasion.

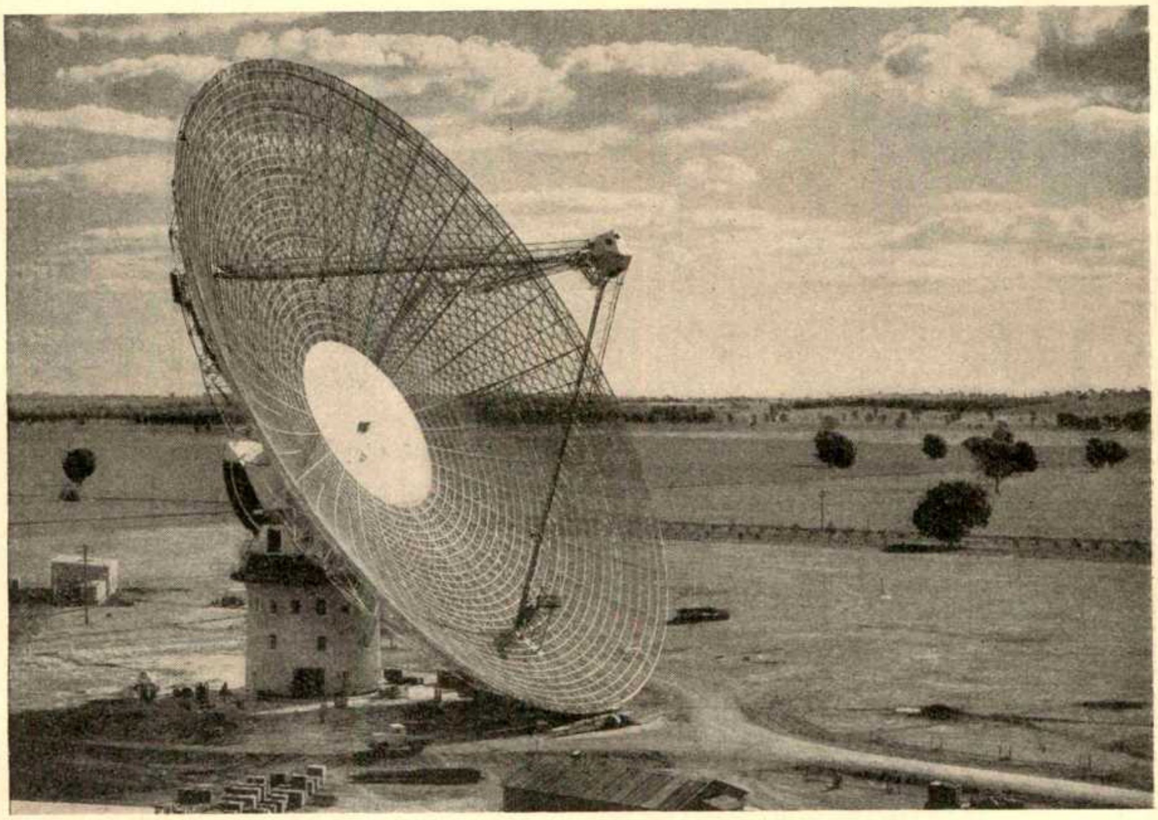

Fig. 1. The completed telescope, tilted down to its lowest position, 60° from the zenith

After being welcomed by Dr F W G White, Chairman of the Commonwealth Scientific and Industrial Research Organization, the Governor-General began by reading a message from H R H The Duke of Edinburgh

"The development of radio astronomy has been one of the great events of modern Science, and the scientists of C S I R O have played a leading part in this important work Their studies of the Sun and the exploration of extraterrestrial space to the remotest parts of the universe have gained the admiration of astronomers everywhere and have brought great credit to Australia

"To-day the radio astronomers of Australia are to be rewarded by the inauguration of a magnificent radio telescope which will enable them to penetrate still further the secrets of the cosmos This occasion marks the culmination of much planning and hard work and I send you my best wishes for the success of your investigations with this new instrument "

His Excellency then discussed the way in which realization of this "Giant Radio Telescope" had come about as the result of a happy conjunction in Australia of several distinct, but all of them propitious, circumstances "Thus conceived and encouraged, the enterprise has leapt forward at a pace which I found both admirable and refreshing " He closed in whimsical mood with a quatrain which ' seemed to float into my mind from an extra-planetary source"

"Twinkle, twinkle radio star
We can't see you you're too far
Now we hear from outer space
How you run your cosmic race "

The next speakers were Dr The Hon D A Cameron, the Minister-in-Charge of the Commonwealth Scientific and Industrial Research Organization, and The Right Hon Lord Casey, who was Minister-in-Charge of the Organization during the early critical stages of the project, and has continued his connexion with it as chairman of the Radio Astronomy Trust

At this stage the Governor-General performed the commissioning ceremony, and a large Australian flag was broken out above the focus cabin, the highest point of the structure Unfortunately, wind gusts of more than 50 m p h interfered with a plan to tilt the dish down towards the assembled crowd The area is normally very calm, which in fact was one of the reasons for its choice, but on this ceremonial occasion the weather was unkind, with wind-speeds at their highest level for several years

Dr Bowen closed the proceedings by outlining some of the plans for the future use of the instrument A number of important observational programmes are ready to start as soon as the present period of extensive tests is completed These include work on the identification of extragalactic sources, and studies of galactic structure, the Magellanic Clouds, bright hydrogen regions, and the planet Jupiter

The new instrument will make a powerful addition to the facilities available to the Australian radio astronomers, but it is also a notable gain for the astronomical world at large To quote Dr Bowen's concluding remarks "When the first urgent tasks of the next few months have been performed, it will be thrown open to astronomers from every part of the world with worthwhile problems to attack We pledge ourselves to work in close collaboration with our fellow scientists from any country and will make this Observatory a rallying point for equipment and information, for techniques and intellects which, together, will lead to further great advances in the science of astronomy"

OBITUARIES

Prof Robert Boutflour, C.B.E.

Prof Robert Boutflour, who had resigned as principal of the Royal Agricultural College in 1958, died on October 27 in Cirencester at the age of seventy-one He was educated at Barnard Castle School and Armstrong College—now King's College, Newcastle upon Tyne

Boutflour's first appointment was lecturer in agriculture with the Lancashire County Council, this was followed by a similar post in the University of Leeds, and in 1921 he was appointed agricultural officer for the County of Lindsey In 1922 he was made chief agricultural officer to the Wiltshire County Council, where he remained until 1926, when he was appointed the first and last national director of dairy husbandry

He is best known for his work on the breeding and management of dairy cattle This he started in Wiltshire, where it was realized that he was a man of sound progressive ideas, and in fact, many years ahead of his time, which is now proved inasmuch as his ideas are now accepted in general practice His fame extended abroad as well as at home, and he is well known to many farmers of the territories he visited in the United States, Canada, Kenya and Australia

While national director of dairy husbandry, he was attached to the Harper Adams Agricultural College, where he established his famous Friesian herd of dairy cattle This enterprise proved to be an outstanding success and enabled him to put into practice those points of management that he had so strenuously advocated to farmers throughout the United Kingdom

Boutflour was an impressive author and wrote many works on farm management in general, and the subject of dairy cattle in particular While his success as a scientist was largely due to his keen powers of observation, coupled with patient and inspired reasoning, his ability to impress audiences or individuals was the result of his enthusiasm, alert mind and logical arguments coupled with a quick wit In character and speech he was always most forthright, but his caustic remarks were usually offset with a characteristic twinkle in his eyes

His appointment as principal of the Royal Agricultural College in 1931 gave him the necessary scope for his ability in organization and administration, and particularly to associate with young people, to whom he was always willing to give advice and encouragement When he retired from the principalship in 1958 he had the satisfaction of knowing that during his term of office he had increased the number of students from 48 to more than 450

During the Second World War, as executive officer for food production in Gloucestershire, he adopted many revolutionary methods to increase the output of food One of his most daring ventures was to plough up the Slimbridge pastures adjoining the River Severn, which for centuries had been the habitat of wild geese His critics said that with this terrific fertility no cereal crop would 'stand', but once again he proved them wrong He was created C.B.E in 1952, and in 1955 he received the Sir Thomas Baxter Prize and Gold Medal for outstanding work in dairy husbandry

However, it is by his personal character that so many will remember him, and among his personal characteristics was a 'human' appreciation of his fellow men and the possession in a very large measure of that great virtue—tolerance His wife, who survives him, was the greatest help to him throughout his varied career, by her companionship and understanding The passing of this colourful character has created a void which will be difficult, if not impossible, to fill, and to the older generation who knew him—and there are so many—Bob Boutflour will always remain in their memory with affection as a generous, likeable and very 'human' person of outstanding ability, while the younger generation will reap the benefit of his scientific work, and the valuable contribution he made to British and, in fact, world agriculture W T PRICE

Dr A. E. Western

ALFRED EDWARD WESTERN, who died on October 11 at the age of eighty-eight, was one of the few who have been able to carry on mathematical research while fully engaged in another profession in his case, that of a solicitor He was educated at Marlborough and at Trinity College, Cambridge, which he entered with an open scholarship in 1892 He was seventh Wrangler in the Mathematical Tripos in 1895, the year in which Bromwich was Senior Wrangler and E. T Whittaker second Wrangler

Dr Western published several memoirs on the theory of algebraic numbers, and one on the theory of groups, during the years 1898–1911, and showed himself to be thoroughly at home in a subject which was then little cultivated in Britain His standing as a mathematician was recognized by the award of the degree of Sc D by the University of Cambridge in 1910 He gradually became more interested in questions of numerical computation, and published several notes giving the numerical evidence which he had found for various conjectured formulæ of Hardy and Littlewood relating to the distribution of primes, to the occurrence of primes of the form $n^2 + 1$, and to Waring's problem

During the last years of his life he was engaged (jointly with Dr J. C P Miller) in completing a table projected by the late Lieut -Colonel A. J C Cunningham, with whom he had formerly collaborated This table, which is essentially a continuation of Jacobi's *Canon Arithmeticus*, is shortly to be published with the help of a bequest made by Cunningham to the London Mathematical Society for the purpose

Dr Western was closely associated with the London Mathematical Society over a long period, and rendered great service to it He became a member of the Council in 1900, and treasurer in 1913 in succession to Sir Joseph Larmor He retired from this office in 1950, and many members will recall the delightful speech he made at a dinner held at that time

As a solicitor, Dr Western was a pioneer in initiating 'legal aid', and it was largely from his work that the legal aid scheme used in courts in Britain developed

He will be remembered by many as a man of great kindliness and of transparent sincerity and honesty of purpose H DAVENPORT

NEWS and VIEWS

Geology at Trinity College, Dublin: Dr R. G. S. Hudson, F R S

THE chair of geology and mineralogy at Trinity College, Dublin, vacated by Prof W D Gill on his appointment to the chair of oil technology at the Imperial College of Science and Technology, London (see *Nature*, 191, 651, 1961), has been filled by the appointment of Dr R G S Hudson, Iveagh Research Fellow in geology at Trinity Dr Hudson, who studied geology at University College, London, under the late Prof E J Garwood, joined the staff of the Geological Department at Leeds in 1922, became professor of geology in 1939 and during 1940–45 acted as consulting geologist to various companies engaged in the search for oil in Great Britain During these years he published mainly on the Dinantian and Namurian of the north of England, demonstrating the rhythmic succession of the Yoredale Series, the stratigraphical relationship of the limestone of the Craven Reef Belt, the pre-Namurian age of the Mid-Craven Fault, and helped in mapping a large part of the Craven Lowlands He also worked with W S Bisat on the goniatite faunas of the Namurian and, in particular, detailed the goniatite succession in the Alport Boring in Derbyshire During 1946–58 he was a senior research geologist and palæontologist with the Iraq Petroleum Company, leading field exploration parties in Kurdistan, Iraq (1949, 1950) and in the Oman Mountains of Arabia (1951, 1952), and publishing on the stratigraphy and faunas of these areas Much of the present knowledge of the Middle East Mesozoic faunas, in particular the stromatoporoids and hydrozoa, is due to his work He has received the Foulerton Award of the Geologists' Association and the Wollaston Award and Murchison Medal of the Geological Society He has also been president of the Yorkshire and the Liverpool Geological Societies and the Palæontological Association, and a vice-president of the Geological Society In 1959 he was made an honorary member of the Société Belge de Géologie et Paléontologie, and in 1961 he was elected to the Royal Society.

The British Nuclear Energy Society

ON January 1, 1962, the British Nuclear Energy Society will be established in succession to the British Nuclear Energy Conference The successful use of nuclear energy demands the application of many divisions of science and technology and a constant interchange of knowledge and experience between those trained primarily in these divisions. It was to provide a channel for this interchange that in 1955 the British Nuclear Energy Conference was established by the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Institution of Electrical Engineers, the Institute of Physics and the Institution of Chemical Engineers, which were joined later by the Iron and Steel Institute, the Institute of Metals, the Institute of Fuel and the Joint Panel on Nuclear Marine Propulsion. The Conference has sought to fill its role principally in three ways: (1) by publishing under one cover, in the *Journal*, all the more important papers on nuclear energy presented to the constituent societies; (2) by keeping members of the individual societies informed of those meetings of the other societies that are devoted to aspects of nuclear energy and making such meetings open to them; (3) by sponsoring meetings on nuclear energy organized either for the Conference by the appropriate societies or, where the subject involves the application of several disciplines, by the Conference itself.

The time has now come to provide a central forum for the discussion of nuclear energy, and it is for this purpose that the British Nuclear Energy Society has been established. The Institution of Civil Engineers has made its premises in Great George Street, Westminster, available as a meeting place, and a regular programme of papers, lectures, symposia and informal discussions is being planned. The Society will (like the Conference) publish a quarterly *Journal* which in addition to reprinting a wide range of important papers will also contain original papers and discussion on them, information and authoritative scientific and technological comment on developments in nuclear energy throughout the world, and reports on the proceedings of meetings of the Society. The first issue of this *Journal* will be in January 1962.

Membership of the new Society will be open to members of all classes of the constituent societies of the British Nuclear Energy Conference and to all who satisfy the Board that they are (to quote the Society's constitution) "actively engaged in the professional, scientific, or technical aspects of the application of nuclear energy and ancillary subjects". Further information can be obtained from the Secretary, British Nuclear Energy Society, Institution of Civil Engineers, Great George Street, London, S.W.1.

Changes in Times of International Time Signal

For more than one hundred years, the Royal Greenwich Observatory has been responsible for providing exact time signals for a wide variety of users both in Britain and abroad. In recent years this service has become increasingly important in various fields of scientific research where extreme accuracy is essential. In order to provide the various users with more frequent opportunities for checking the time, the present twice-daily transmissions from Rugby were increased to four as from December 1. This will mean that the transmissions on the low frequency of 16 kc./s. now radiated at 10 a.m. and 6 p.m. will be superseded by signals at 3 a.m., 9 a.m., 3 p.m. and 9 p.m. There will, however, be no change in the form of the signals. To ensure a world-wide coverage, the 10 a.m. and 6 p.m. broadcasts have also been transmitted on short wave. This service will continue after December 1, but the times will be changed to 9 a.m. and 9 p.m. As long ago as 1833, the Royal Greenwich Observatory provided hourly time signals for the operation of 'time balls', which were devices consisting of a large ball secured to the top of a mast and released by a special catch at a precise time. One such ball is still in use in the grounds of the old Observatory at Greenwich. The hourly transmissions continued for many years, but this service has now diminished to almost negligible proportions and, in fact, the only user is the G.P.O. for the Talking Clock (*TIM*) which has been in operation since 1936. The reason for the falling-off of the requirement for the hourly Greenwich transmissions was the inauguration in 1924 of the B.B.C.'s Greenwich time signal, which is claimed to be as accurate as possible.

The Federal Council for Science and Technology

According to *Scientific Information Notes* (3, No. 5, October–November 1961), the U.S. Federal Council for Science and Technology will in future, to help scientific periodicals meet the cost of publishing research results, pay, as a necessary part of research costs under Federal grants and contracts, page charges for publication of research results. The research papers concerned must report research work supported by the Government and the charges must be levied impartially on all research papers published by the periodical. Payment of such charges must not be a condition for acceptance of manuscripts by the periodical, and the periodicals must not be operated for profit. The new policy was stimulated by the National Science Foundation. The National Science Foundation has also placed a contract for computer-aided research with the Ramo-Wooldridge Corporation, Canogen Park, California, to further the investigation of new techniques for processing language data. Under the contract, 300,000 words of Russian text, representing five fields of study, will be used for dictionary compilation. Concurrently, the translation programme will be used for mechanical translation research in which the translation will be automatically compared on the computer with the results of a previous revision of the dictionary. Part of the investigation will be to consider the introduction of modifications and supplements into the programme. At the Institute for Scientific Information, Philadelphia, molecular formulæ of several hundred randomly selected chemicals have been calculated on an electronic computer, using a newly constructed recognition grammar of chemical nomenclature, and the new grammar enables the computer to understand the chemical names fed to it by a typist. The linguistic analyses indicate that the procedure can be used manually by chemists in training clerks, librarians and indexers to calculate a molecular formula from a chemical name, and the new computer technique is being incorporated into the preparation of *Index Chemicus*.

National Central Library

The forty-fifth annual report of the Executive Committee of the National Central Library (Pp. 24. London: National Central Library, 1961) covers the period March 1, 1960–March 31, 1961, in which, on an average, applications for loans increased by 4.6 per cent each month over the corresponding month in the previous year, while the percentage dealt with successfully increased from 72·22 to 74·13. Volumes added to the general stock by purchase rose from 1,129 to 1,952, largely in foreign languages, and nearly 18 per cent of requests were met directly by loans from the Library's own stock, compared with 16 per cent the previous year. Satisfactory progress is reported in the first stage of the project for dealing with the arrears of cataloguing, but further funds are necessary for dealing with the later stages of the project. The Library's British National Book Centre has now extended its service to include foreign libraries, and some 19,977 specially requested books and periodical volumes and parts were allocated to 126 foreign libraries, while in return 3,987 offers of foreign material were made by the foreign libraries benefiting. Of the total issues of 90,612 volumes, 16,555 were to university libraries, 10,255 to special outlier libraries, 2,653 to Government departments, 3,414 to industrial and research organizations, and 4,520 to overseas libraries. The university libraries lent 29,826 books, compared with 28,611 in the previous year. The Library itself supplied 641 microfilms and 326 photostat copies, and of these 491 microfilms and 187 photostat copies came from co-operating libraries in the United Kingdom. Foreign libraries supplied 732 microfilms and photostat copies.

The Institute of Personnel Management

THE annual report of the Council of the Institute of Personnel Management for 1960–61 records an increase of 441 in membership to 4,938, and the Information Service is now handling about double the number of inquiries in 1959 (Pp. 31. London: Institute of Personnel Management, 1961). During the year, views on the proposed Government Bill on Health, Welfare and Safety in Shops, Offices and Railway Premises were submitted by the Institute to the Ministry of Labour. A paper by A. B. Cherns on priorities for research in the social services in industry was published in the Institute's journal, and during the year a sub-committee on research was formed which convened a meeting of representatives of research bodies in this field to advise it, at which the proposal that the Institute should develop its research role was welcomed. Two important new broadsheets have been published, one by H. E. Roff and T. E. Watson, dealing with job analysis, and the other by J. R. Armstrong on supervisory training, and an address by Sir Ben Lockspeiser, "Man and his Machines, Automation and Computation—their Origins and Effects", given at the 1960 National Conference, has been published as an occasional paper. Particulars of this conference and of the regional conferences held during the year are also given in the report.

Science and Public Health

THE annual report for 1960 of the scientific adviser, Dr. S. G. Burgess, of the Scientific Branch, Public Health Department, London County Council, at present organized in eight sections, records that 42,090 samples were examined during the year (Pp. 60. London: London County Council, 1961. 1*s*. 3*d*.). Some 90 per cent of the increase of 6,800 samples is due to the analysis of air samples necessitated by safety precautions against the leakage of inflammable sludge gas at the Northern Outfall Works. During the year the resources of the Board were made available to the Metropolitan borough councils, and investigation of noise, and nuisance arising from noise, in a large area of London was commenced in collaboration with the Department of Scientific and Industrial Research. A light-weight concrete based on an expanded aggregate was used for the construction of a thirteen-storey block of flats, and the Scientific Branch co-operated with the architect in solving many problems associated with the design. The practicability of laying hot asphalt over an expanded polystyrene roof insulation was also investigated, a new washing technique developed which offers considerable savings in laundry processes, while other special investigations were concerned with methane gas detectors, impurities in sludge gas and deposits in sludge gas lines and flame traps. New laboratories were completed at the Northern Outfall Works and a new Building Materials Laboratory at County Hall, London.

Corrosion Science

THE first quarterly issue of a new international journal devoted to the science of corrosion and protection of metals and entitled *Corrosion Science* made its appearance in August (1, No. 1. An International Journal of the Science of Corrosion and Protection of Metals. Pp. 76. (London and New York: Pergamon Press, 1961.) Annual subscription (*A*) for libraries, Government establishments and research institutions, 140*s*., 20 dollars; (*B*) for individuals who write directly to the publishers certifying that the journal is for their personal use, 70*s*., 10 dollars.) The journal is published by Pergamon Press under the guidance of an executive editorial board consisting of C. Edeleanu, J. G. Hines, T. P. Hoar and L. L. Shrier of Great Britain, M. Pourbaix of Belgium and M. J. Pryor of the United States. The standard of reproduction is of the usual high quality associated with Pergamon Press. The editorial notice mentions, among other things, that papers on corrosion are at present published in many diverse chemical, metallurgy and engineering journals, and expresses the hope that the new journal will help to concentrate this information. That there will be an adequate flow of papers of appropriate quality to the new journal seems assured, in view of the continually increasing amount of work in this field.

The first issue of a new journal always presents some difficulties for both publisher and reader, for the former in deciding how to obtain appropriate papers, and for the reader in deciding whether the first issue is likely to be representative of the eventual standing of the journal. In the present case there are five papers occupying 75 pages, with sufficient breadth of content to offer something of interest to the majority of corrosion scientists. The composition of the executive editorial board is such that the journal should establish itself as of high repute and with a continuing breadth of appeal.

The Australian Museum, Sydney

THE September issue of the *Australian Museum Magazine* (13, No. 11, September 15, 1961) contains illustrated articles on the boomerang, insect migration, vampire bats—true and false—the piranha and meteorites. It is recorded that Mr. F. A. McNeill retired from the curatorship of the Department of Crustacea and Cœlenterates after 47 years service. He was a specialist on Australian Crustacea. An exhibit on whales and whaling has been completed. It contains models of fifteen different species, of whaling ships and of whales being flensed on deck. Maps show the areas in the Antarctic in which whaling is carried out, the location of shore stations, and the areas in which whales are protected.

Automatic Data Processing

A PUBLICATION issued by the Department of Scientific and Industrial Research (*Automatic Data Processing*. By Derek Wragge Morley. Pp. iv+76+8 plates. London: H.M.S.O., 1961. 6*s*. net) seeks to provide guidance to the public about available techniques and machines in this field. The booklet is well produced, but the journalistic style and lack of critical appreciation of the history and implications of the subject will make it considerably less valuable than might otherwise have been the case. A particular shortcoming is the complete absence of any reference to more authoritative literature—the reader is directed to various manufacturers for further information. While this may be suitable for intending purchasers, it is unlikely to be helpful for the layman who wishes to gain a fuller understanding of the subject.

The latest issue of the *Philips Technical Review* (23, 1, October 1961) contains a description of a new digital computer *Pascal*. This machine, installed at the Philips Computing Centre at Eindhoven, has a well-balanced, parallel operation, arithmetic unit the speed of operation of which varies between 10 and 73 μsec for the various operations. The machine is a binary one with optional floating-point facilities. As may be imagined from its origin, it has a large magnetic core store as well as drums, tape and a plugboard. Input and output are in punched tape or cards and on magnetic tape and the speeds considerably exceed those of standard telegraph and business machine practice. The components used in the machine include valves, transistors and diodes since, in addition to being a useful calculator, the machine will provide information on component performance.

Technical Papers of the Sandia Corporation

THE bibliography *SCR*-255 is a revision of *SCR*-150 and consists of a cumulative numerical list of technical papers of the Sandia Corporation, Albuquerque, which are available to the public (Pp. 120. Albuquerque, New Mexico: Sandia Corporation. Obtainable from the Office of Technical Services, Department of Commerce, Washington 25, D.C., 1961. 2.50 dollars.) The prices of printed or photographic and microfilm copies are included in most cases. The title list includes in addition a section on engineering drawing and specifications on sale through the United States Atomic Energy Commission's Engineering Materials Section at Oak Ridge. The contents of the bibliography is divided into eight sections, dealing with the reprint and monograph series, technical reports, development reports, technical memoranda, divided into annual series covering 1953–60 inclusive, manuscript releases, miscellaneous papers, and engineering materials. The Sandia Corporation is a prime contractor to the Atomic Energy Commission.

Plasma Physics

REPORT No. 18 of the Danish Atomic Energy Commission Research Establishment, Riso, contains the essential part of the material presented in the form of lectures or at the seminars during the international summer school on plasma physics held there during August 1–12, 1960 (Pp. viii+645. Riso, Roskilde: Danish Atomic Energy Commission Research Establishment, 1961. 60 D. Kr.) The lecturers were distinguished scientists from Denmark, France, Germany, The Netherlands, United States of America and Great Britain. The director was Dr. M. N. Rosenbluth (General Atomic, San Diego, California) and 130 students from twenty-four countries attended. The contents of the report, compiled by C. F. Wandel (Riso Establishment), consist of the short general introduction to plasma physics given by the director, followed by thirty-six articles grouped under the headings: single-particle motion, magnetohydrodynamics, fundamental equations, stability, relaxation, radiation, thermonuclear aspects, pinch and shock apparatus, concepts covering the stellarator and the mirror machine, and plasma waves and diagnostics. Not all the articles are in the form of lectures, some are reprints of published papers. The standard of the lectures, though representing a good introduction to and clear statement of the basic principles of plasma physics, nevertheless is somewhat more advanced than, for example, Lyman Spitzer's book. The report should prove an admirable text for postgraduate students and research workers who want to pursue an advanced course in plasma physics before proceeding to tackle the latest publications on the subject.

British Chemicals and their Manufacturers

THE Association of British Chemical Manufacturers has recently issued a guide, *British Chemicals and their Manufacturers*, which supplies information on all chemical products made by its members (Pp. 219. London: Association of British Chemical Manufacturers, 1961.) The booklet is far more than a guide, and will be invaluable as a reference book to purchasers and producers alike. It will certainly prove to be indispensable in all academic and industrial research departments throughout the United Kingdom. The booklet consists essentially of five sections including the grouping of chemical industries, a directory of members of the Association, classified lists of British chemical products (with a special section on indicators and microscopical stains), lists of proprietary and trade names and proprietary and trade marks. The information is in each case presented in the clearest possible way. The first section provides information on the nature of the products, that is, their grade, whether heavy or fine, their origin, for example coal-tar distillation products, and their type such as dyestuffs, explosives, fats, glycerine, greases, soaps, etc., and those suitable for pest control. The directory, besides giving the name and address of members, also supplies telegraphic addresses, telephone and telex numbers. All in all, 366 industries are listed, and supplemented by a list of affiliated associations. Products are listed under their chemical names, and coded references give means of tracing the producer. In each case it is indicated whether the chemicals are of commercial grade or fine, pharmaceutical, pure, analytical and similar grades. The lists of proprietary and trade names will certainly be of great assistance to all editors who have to decide what is, and what is not, a registered trade name, and hence what should have quotation marks.

Autonomic Nervous System and the Occurrence of Visceral Lesions

Hiroshi Itoh, Teizo Kasahara, Kazua Amano, Koh Okamoto and Samon Tanabe, of the Department of Pharmacology, Yokohama University School of Medicine, have shown histologically that a chronic chemical stimulation on a defined region of the skin produced lesions in both renal cortices (*Yokohama Med. Bull.*, 12, No. 3; June 1961). They have now followed the development of these lesions by functional examinations over a period of four months. The state of intrarenal circulation was investigated to determine the pathogenesis of the lesions, and the renal function was examined in several ways. The test for albuminuria and Volhard's test proved to be positive, but disorders of renal function could not be detected by other methods. Albuminuria was confirmed at two stages of the experiment, namely, on the twenty-eighth and fifty-fifth days Investigations made on the fifty-fifth and seventy-sixth days on the renal cortical region suggested some disorder of the intrarenal circulation Over a period of four months the systolic blood pressure did not rise significantly above the level in the pretreated period The authors suggest that the lesions may have been caused by impulses generated in the afferent nerve, following repeated chemical stimulation on the skin, passing through a reflex arc involving the higher central nervous system These continue to the intrarenal arteries by way of the sympathetic nerve, and the resulting ischæmia in the renal cortex may be the cause of the degeneration of the renal parenchymal cells, especially those of proximal convoluted tubules The functional changes of the kidney are slight in the period before the lesions advance but they are readily perceived by histological examination

An Inventory of Abstracting Services

The Fédération Internationale de Documentation, 7 Hofweg, The Hague, Netherlands, is preparing, with financial assistance from the National Science Foundation in Washington, D C, a comprehensive inventory of abstracting services covering the fields of science, technology and social sciences It is expected that the study will take two years The data will be collected by means of a questionnaire to be distributed at the beginning of February 1962 Besides gaining information about the nature and scope of each abstracting service, the questionnaire will also determine the number of periodicals consulted during the year, the existence of a reproduction service and whether translations can be obtained On completion of this project, the Fédération plans to establish an international information centre, the first object being to give supplementary information on data revealed by the questionnaire It is hoped that all abstracting services will co-operate in the scheme

Wellcome Senior Research Fellowships in Clinical Science

To encourage medically qualified workers of exceptional ability to embark on careers of clinical research within the United Kingdom, the Wellcome Trustees are prepared to award one or two Wellcome Senior Research Fellowships in this field in 1962 The professors in charge of university departments of medicine, surgery and obstetrics in the United Kingdom are invited to put forward confidential nominations for these awards Direct personal applications by candidates for these Fellowships will not be considered The Fellowships will be awarded for one year in the first instance and will be renewable over four more years It will be a condition of the appointment that the Fellow should be granted the status and responsibilities of a lecturer in the university department in which he is employed On the assumption that the age of the Fellow at appointment will be about thirty, the stipend offered over the five-year period will be £1,900 a year, rising by increments of £150 to £2,500 Further information can be obtained from the Scientific Secretary, The Wellcome Trust, 52 Queen Anne Street, London, W 1

Christmas Lectures for Young People

Among the lectures organized for young people during Christmas and the following weeks are The one hundred and thirty-second course of Christmas lectures at the Royal Institution, to be delivered by Sir Lawrence Bragg on "Electricity", including "What is Electricity?" (December 28), "How Electricity Travels" (December 30), "Motors and Dynamos" (January 2), "Electrical Oscillations and Electromagnetic Waves" (January 4), "Our Electrical Supply" (January 6), and "Conveying Information by Electricity" (January 9) Further information can be obtained from the Royal Institution, 21 Albemarle Street, London, W 1 Five children's Christmas holiday lectures on "The Painter, the Anatomist and the Surgeon" (Mr H Thompson, January 1), "Science in Crime Detection" (Dr K Simpson, January 2), "Family Life in Russia To-day" (Dr J. Hunt, January 3), "The Romance of Huntington's Chorea" (Dr. Macdonald Critchley, January 4) and "How and Why We Hear" (Mr T Cawthorne, January 5) at the Royal Society of Medicine at 2 30 p m. Further information can be obtained from the Assistant Secretary, Royal Society of Medicine, 1 Wimpole Street, London, W.1 A young people's lecture, to be delivered by Prof M Stacey on "Nature's Plastics" at the Plastics Institute on January 5, at 2 30 p m Further information can be obtained from the Plastics Institute, 6 Mandeville Place, London, W.1

Announcements

Prof N R Dhar, recently head of the Chemistry Department and director of the Sheila Dhar Institute of Soil Science, University of Allahabad, has been elected as a corresponding member of the Paris Academy of Sciences in the Chemistry Section

Mr P S Briggs, of T N and F H Briggs (Tanners), Ltd, Leicester, has been appointed chairman of the Council of the British Leather Manufacturers' Research Association in succession to Mr E. A Hutchings, who has left the leather industry

Dr Olivier Heroux has been appointed scientist-in-residence at the U S Naval Radiological Defense Laboratory, San Francisco, California. This is the first appointment under a new programme at the Laboratory for visiting distinguished scientists from other scientific communities Dr Heroux is a member of the Canadian National Research Council and will be at the Laboratory during leave of absence of one year from his post in Canada

The annual meeting of the American Mathematical Society will be held at the Sheraton-Gibson Hotel, Cincinnati. during January 22–25 Further information can be obtained from J W T Youngs, American Mathematical Society, Bloomington, Indiana

Erratum Dr G B Robertson writes In "Crystal and Molecular Structure of Diphenyl" (*Nature*, 191, 593, 1961) the value of the constant in the asymmetric-unit plane equation was reported incorrectly due to a computational error The correct value of this constant is 0 00864, the equation of the plane is

$$-0\ 30584\,X + 0\ 55575\,Y + 0\ 77305\,Z' = 0\ 00864$$

and the perpendicular separation between the ring planes is ~ 0 017 Å (not ~ 0 2 Å) This separation is not statistically significant and the two rings are, therefore, coplanar within the limits of the experimental error

NEMATOLOGY AT THE IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, LONDON

ON October 23, at Silwood Park, Sunninghill, the new Shell Parasitology Building was formally handed over to the Imperial College of Science and Technology. A plaque inside the door explains that "These laboratories were erected with the aid of a generous benefaction from Shell International Chemical Co., Ltd., in support of research into parasitology".

The new building consists of two floors, each of 2,400 sq. ft., and a small basement of 400 sq. ft. On the ground-floor are a lecture room and well-equipped teaching laboratory for the one-year postgraduate course in nematology, a preparation room for extracting nematodes from soils or from plant materials, and a radio-tracer room. On the first floor are three staff laboratories, a large laboratory for higher-degree students, a small teaching laboratory for undergraduates specializing in parasitology, and a photographic dark room. In the basement are three constant-temperature rooms separately controllable within the range 5°–30° C.

While research projects extend over the field of general parasitology (recent work has dealt with protozoal parasites of insects, and the bionomics of sheep trichostrongyle larvæ, for example), major prominence is given to nematology. The most pressing requirement was to house the postgraduate nematology course: it will now be possible to accommodate with comfort eight students, and at need up to twelve, instead of only four as hitherto.

This one-year course aims at giving a grounding in: (1) general nematology with an emphasis on plant-parasitic and soil-inhabiting species; (2) the principles of control by chemical and other means; (3) the art of experimentation. The course, the first of its kind in Great Britain, has a strong bias towards practical techniques and research methods. Of a total of fifteen students to date, ten have come from seven overseas countries, and it is hoped to maintain this overseas appeal, if only because plant eelworms are of great economic importance in tropical and subtropical lands.

The new laboratories are well equipped with such standard items as microscopes and calculating machines, and radiotracer equipment includes a versatile scaler with scintillation head, and monitor. Work is in progress with labelled chemical fumigants.

B. G. Peters

THE HUMBER LABORATORY

THE Humber Laboratory of the Department of Scientific and Industrial Research at Hull held two open days during November 9–10. This establishment is a branch laboratory of the Torry Research Station, Aberdeen, and like its parent Station is concerned with research on the handling and processing of fish from the time of catching to retail sale. Since the Humber Laboratory was opened in 1952 it has dealt with an ever-increasing volume of work, particularly in applied research and in giving scientific information to the fish trade. The buildings have been extended twice during the short life of the station, and the recent open days marked the putting into service of a new block containing laboratories, library, and a lecture theatre.

The exhibits at the open days were not limited to the activities of the Humber Laboratory itself, but also covered the much wider range of subjects dealt with at the Torry Research Station. Prominent among these is the matter of freezing fish at sea. Poorer catches from present fishing grounds and the loss of some traditional grounds by the extension of territorial limits are encouraging longer voyages by British distant-water trawlers. This in turn means that the use of ice is no longer an adequate method of preserving all the catch in an edible condition. Freezing and cold storage is one obvious answer to the problem of preservation, but the successful application of this technique has required the co-operation of scientists and engineers trained in widely different disciplines. This was illustrated by exhibits which range from techniques of showing the damage to muscle cells during freezing, and of estimating the extent of denaturation of proteins in cold store, to a model of freezing plant designed to work on small ships in rough weather. The work of the Torry

Research Station has been particularly concentrated on the design of trawlers which will freeze part of the catch rather than on factory ships to freeze and process all of it at sea, and a model of one of the first vessels of this type to operate commercially was exhibited.

When frozen fish is used on any large scale the problem of thawing for further processing becomes a matter of very considerable importance. The thermal diffusivity of wet fish is very much less than that of frozen fish, and hence the thawing of a block of frozen fish in warm air is a self-retarding process. Also the temperature gradient permissible in such a process is limited by the need to minimize the spoilage of the fish already thawed. This has led to examination of dielectric heating as a means of thawing, and a practicable technique has been worked out. A pilot plant of 6-kW. output operating at 36 Mc./s. was on show. In this, frozen fish was carried on a conveyor belt between the plates of a condenser and 2-st. blocks were thawed in about 15 min. Equipment of this type developed by the Torry Research Station has recently been put into commercial operation.

Despite the attention given to frozen fish, work on wet fish has been by no means neglected. A number of exhibits were concerned with the effect of temperature on spoilage by reference to the chemical and bacteriological changes involved. The Humber Laboratory has been particularly concerned with the temperature of fish throughout the chain of distribution and has conducted temperature surveys at all stages from dock side to retail shop. This work has entailed the development of a number of special instruments, notable among which is a spear-type resistance thermometer in which the resistance element is contained within a hypodermic needle. For making temperature measurements by thermocouple on board moving vehicles, the conventional electronic self-balancing potentiometer is not a very suitable instrument. It is too large and its power consumption is too great. The Humber Laboratory has developed a small, battery-operated potentiometer in which balance is indicated by a 'magic eye', and this has been used successfully for many measurements on lorries. Another simple and effective instrument is the 'temperature indicator' which shows a sharp change in colour when it exceeds a given temperature. This device consists of a tube of 1 ml. capacity containing two aqueous solutions separated by a frozen non-aqueous layer.

The Torry Research Station has long been concerned with the smoking of fish, and when the Humber Laboratory was opened most of the applied work on this subject was transferred to Hull. The 'Torry kiln' has made considerable strides towards becoming the conventional piece of apparatus for smoking fish. Examples of the wide range of smoked products that can be made in a Torry kiln were on show together with sectioned models of both Torry and traditional kilns. The Humber Laboratory has devoted considerable effort to the question of the more efficient production of wood smoke, and has developed a continuous, automatically controlled smoke producer which uses a fluidized bed of sawdust. Tests have also been carried out to evaluate the performance of various commercial smoke producers, and a number of these machines was on show.

The work on smoking has also led to the development of various new instruments. A simple robust smoke density meter operating on the usual lamp and photocell principle was exhibited together with a modification of it, the 'smoke density integrator', which indicates directly smoke density multiplied by time—a quantity of great importance in smoke curing. Although more recent background work has shown that the invisible vapours in wood smoke are of more importance than the visible particles in giving smoked products their characteristic odour and flavour, smoke density meters are still of very considerable value. A technique for measuring the concentration of vapours was also exhibited.

Much of the work of the Humber Laboratory which has been of the most direct value to the fish industry has depended less on the discovery of new facts than on the practical application of well-established knowledge. For example, very considerable assistance has been given in setting up quality-control schemes which are based on taste panel techniques developed at the Torry Research Station in past years. Similarly, much-needed advice on the best methods of packing fish in ice for inland transport is merely the application to fish of the well-known laws governing the transient state conduction of heat. Work of this nature is extremely necessary in a station of the Department of Scientific and Industrial Research which serves the needs of an industry which as a whole is technically backward, and in which scientific staff are found only in the largest and most progressive companies.

D. L. Nicol

FOOD AND AGRICULTURE IN DEVELOPING COUNTRIES

On October 13 the Nutrition Society held a symposium, at the National Institute for Research in Dairying, Shinfield, Reading, under the chairmanship of the director, Prof. R. G. Baskett, on agricultural problems in developing countries. The latest Food and Agriculture Organization review of food and agriculture* shows that the developed areas still have an abundance, even a surplus of agricultural products, while malnutrition and hunger are the order of the day in many less-developed countries. The past decade has seen a very considerable expansion in the world output of food. For example, the average annual combined output of wheat, rice and maize (including the Food and Agriculture Organization estimates for the U.S.S.R. and mainland China) rose from about 470 million long tons in 1948–52, to about 720 million long tons in 1959. This remarkable technical achievement rests far more on increased efficiency of production than on increases in crop area. The overall food output per head has risen, but this covers dangerous decreases in Latin America and Oceania, and little change in Africa, as well as considerable increases in Europe (where population growth has been slower than elsewhere), North America and the Near East. In the Far East, where food production per head fell sharply during the War years, the pre-war standard, low as it was, has been restored by increases in food production of about 3 per cent per annum The very considerable increases in food production claimed in China since 1950 are perhaps no more than an intensification of this general trend

---

* Food and Agriculture Organization of the United Nations, Rome. *The State of Food and Agriculture*, 1961. Pp. viii+177. (Rome: Food and Agriculture Organization of the United Nations; London: H.M.S.O., 1961.) 10*s*.; 2 dollars.

In the past two or three years, however, food output has been more static, and in 1961 (including the disastrous harvests reported from China) total production was probably no greater than in 1960 International trade and co-operation are moving part of the Western surpluses into the needy areas, but there are not enough railway wagons, ships, elevators and sacks in the world to touch more than the fringes of the problem For the hungry countries, continued increase in their own output, and particularly in yield per acre, is the only answer Most of them have already done a good deal, as the Food and Agriculture Organization figures show, but the great disparity in yield per acre between the best and the worst indicates that far more could be done, particularly in India and Pakistan, which harbour one-quarter of the world's cattle and where the crop yields are among the lowest in the world

The Nutrition Society meeting devoted itself largely to this question, with particular reference to tropical areas Prof L Dudley Stamp spoke on the climatic limitations to development in the tropics He distinguished first between the monotonous climate of the humid equatorial regions and the alternately wet and dry climate of the very diverse regions which he included in the tropics proper In neither area does lack of heat limit plant growth, but in the latter variability of rainfall, in amount and in timing, is often pronounced North and south of these regions lies the tropical arid zone, taken by the United Nations Educational, Scientific and Cultural Organization to lie beyond the 20-in (500 mm) isohyets

At tropical temperatures soils weather deeply and organic matter is rapidly oxidized, while leaching removes plant nutrients beyond the reach of crops, though not of trees Prof Stamp felt that shifting cultivation, with hoes (and weeds) and without ploughs or tractors, might represent the best scientific answer to the land management problem in the humid tropics (Clearly the many successful examples of plantation production of perennial crops must represent at least an exception to this generalization, though certainly in high rainfall areas the removal of vegetation, even for a very short period, in land clearing, is bound to create difficult or even dangerous hydrographic situations) In the dry areas, the accumulation of salts and the formation of pans, together with erosion, can produce arid semi-deserts In all areas of seasonal rainfall the heaviest agricultural tasks of the year fall on man and beast when they are weakened by the privations of the hungry season, and during the rains there are risks of flooding Water control and irrigation, Prof Stamp believes, are essential to development in all three regions The indirect consequences of the tropical climate such as deterioration of stored food, and the heavy burden of insect and other pests and diseases of plants, animals and man, are also important

To Prof A H Bunting (University of Reading), who spoke next on the problems of improving arable output, the impression left, though perhaps unintentionally, by Prof Stamp seemed unduly pessimistic In many developing countries encouraging increases in food production have been reported, and impressive yields have been achieved in some There are two parts to the problem of improvement the intensification of production and the development of new agricultural land

Apart from water, the tropical environment is by no means inherently unfavourable for crop production The highest agricultural dry-matter yields so far recorded in the world are in sugar cane in Hawaii (around 30 tons dry matter/acre/year) The poor yields of peasant production must be compared, not with those of modern scientific farming, but with peasant yields in medieval Europe Intensification is to be sought through improvements in protoplasm, production, and protection There are many examples of improvement of yield, quality and disease resistance in tropical crops by selection and breeding Better production often requires better land use, and the abandonment of shifting cultivation, but this can only come as part of a general process of improvement, usually on a regional scale On a smaller scale, improved rotations, fertilizers, timely and sufficiently dense sowing, and the use of mechanization (particularly at times of peak labour input) have all been shown to pay dividends Crop protection, including weed control, with the help of agricultural chemicals is well established for export crops in many tropical areas Seed schemes, in which dressed seed of improved varieties is supplied at sowing time by an official organization, already exist in cotton and other crops the general extension of such schemes would be a powerful aid to progress

The development of new agricultural areas was illustrated by photographs from the Sudan rainlands, where many millions of acres of land suitable for arable production lie unused for lack of perennial water supplies

Dr J C Shaw (Food and Agriculture Organization), speaking on animal production problems, estimated that the annual deficit of animal protein in human diets (which is especially marked in the Far East) is equivalent to 1 8 million metric tons of non-fat milk solids A Food and Agriculture Organization panel assessing livestock problems has given the highest priority to nutrition, followed by disease and management, with breeding last In cattle, better nutrition means better management of better grazing plus the conservation of cereal and legume feeds and of forage (Clearly this means that animal production, especially in drier areas, depends entirely on successful arable farming, but the converse is not necessarily true, as those who have advocated "ley farming in the tropics" seem to believe) Much work is needed on the improvement of forage species, particularly legumes, on the intake of food and its nutritional value, and on the nutritional requirements of cattle in the tropics Since much of the feed in the dry season comes from nutritionally poor materials, means of conserving or increasing their feed value must be sought For small animals, farming waste products are important, and formula feeds will have to be devised Breeding, in rigorous climates, should be based first on investigations of the productivity and improvement of the existing livestock, and should not necessarily be based on crossing programmes using improved stock from temperate countries Generally, in developing countries, the shortage is not of animal agronomists but of scientific information more modern veterinary schools are needed.

Dr Shaw's assessment of the priorities in animal production was closely supported by Mr T J Lansbury, recently of the University College of Ghana He, too, gave the highest priority to nutrition, which appears far more important in limiting the output of West African cattle (and also of goats, sheep and poultry) at present than their inherent characteristics Drought leads to shortage of feed and of water, and may lead to losses of 25 per cent of live weight in a single season The improvement of water supplies by conservation requires planned use of grazing, while the problem of dry-season feed supplements has scarcely been tackled, partly because there is little information on the composition of animal feeds in the savannah regions The West African ox does not seem to possess the superior digestive powers with which it is credited, and indeed digestibility is reduced when animals are fed on a low plane of nutrition, particularly in respect of phosphorus and protein Basic work on all these matters, which would no doubt include studies of urea and other non-protein nitrogen sources, is needed on the spot

Introduced varieties of pigs and poultry can do well in West Africa Pigmeat is not in demand, but great expansion of egg production is possible if the birds are properly fed and cared for and not regarded as mere scavengers An industry based on imported chicks is developing, but serious nutritional problems (protein, vitamins B and others, calcium and other minerals) remain to be overcome An industry for feeding-stuffs could be based on local materials which are at present exported for the formulation of feeds in Europe

The last speaker, Mr R S Rack, based his contribution on his remarkable work in the practical development of native fishing industries in Northern Rhodesia His address was notable for its active concern with the human problems of agricultural development He pointed out that the people of undeveloped countries have their own technical and social adaptations to their environment, and that the technological basis of their economy cannot be altered in isolation from its personal and social context This difficulty shows itself in attitudes to organization and work discipline (whether self-imposed or not) and to the employment of time, and in the obstacles often presented by traditional habits and customs The simple poverty of the native fisherman, and his social and family obligations, may prohibit the accumulation of capital, the size of his undertaking may in any event be too small to allow a single technical step (such as the purchase of an outboard motor) unless his whole scale of operation can be altered to take full advantage of it Other problems include the supply of fish, the availability of technically competent and equipped fishermen, and the existence or possibility of markets and suitable transport These factors were illustrated by an account of the successful measures taken since 1951 to improve the supply of fish (whether fresh, as a staple food, or dried as a relish in a cereal diet) to the Rhodesian Copper Belt, which involved an ice plant, a boat-building school, a marketing advisory organization and the encouragement of African traders, and is to lead on to a fisheries school which will teach navigation, the handling of powered boats and book-keeping in addition to the techniques of catching and preserving fish Another example arose from the development of a fishing industry among the traditionally non-fishing Tongas when they were resettled because of the construction of the Kariba Dam, and a third from the improvement of a sardine-type fishery on Lake Tanganyika

In the discussion following the papers, an interesting food chain involving water hyacinth, pigs and fish was described by Prof Stamp from Hong Kong, and some disagreement was evident on the usefulness of imported stock in the tropics

The Food and Agriculture Organization report, already mentioned, also deals with human and organizational problems, on a regional scale, in two special chapters One, on land reform and institutional change, surveys the situation in the main regions of the world and then discusses particular problems such as tenancy, financial support, marketing, settlement and community development The second is on the organization of extension education and research in Africa, Asia and Latin America Taken as a whole, the report is, as usual, a valuable and informative survey.

The meeting, and the report, justify a degree of optimism not only about the technical possibilities but also about the chances that they will be in part realized during the next two or three generations The social and historical imponderables are too great to make any further prediction useful but it is impossible to avoid the conclusion that a general limitation of human numbers is ultimately desirable if a measure of dignity and worthiness of human life is ever to be achieved

A H Bunting

SCANNING TECHNIQUES IN BIOLOGICAL AND MEDICAL MICROSCOPY

A CONFERENCE on the principles and applications of scanning methods in the microscopy of biological and medical specimens, arranged by the New York Academy of Sciences, was held in the Henry Hudson Hotel, New York, during October 5–6 Fourteen papers were presented in the four sessions of the meeting, and all but one were concerned with optical microscopy, the exception being on electron and X-ray scanning microscopy

The main group of contributions ranged from the straight application of television in microscopical observation to the design of a complicated flying-spot system for sizing cells M J Kopac (Graduate School of Arts and Sciences, New York University) described the use of closed-circuit television in connexion with the micro-surgical technique he has developed for operating on single cells At present the micro-instruments, of which there may be as many as eight in use in a single operation, are manipulated by hand It is planned to adapt the electronic techniques used for tracking targets in the air so as to control the movement of microneedles and micropipettes with servo-motors

Scanning techniques are especially useful for cytochemical studies of transient processes in cells C N Loeser and S S West (School of Medicine, Western Reserve University, Cleveland, Ohio) have been using a highly sensitive 'Intensifier Image Orthicon' television camera to record fluorescence emission spectra from individual Ehrlich ascites cells, stained with acridine orange The average uptake of dye per cell has been determined and correlated with the spectral measurements For quantitative investigations in the ultra-violet, two approaches are being followed G Z Williams (National Institutes of Health, Bethesda) and R G. Neuhauser (Radio Corporation of America, Lancaster), described the use of a new 'Vidicon' television camera sensitive to the ultra-violet as an image storage detector and for time-lapse work They obtain oscilloscope tracings of the changing ultra-violet absorption of single living cells, allowing deductions about reaction-rates On the other hand, V K Zworykin and C Berkeley (Rockefeller Institute, New York) have been exploring applications of the colour-translating television microscope In this instrument, the specimen is illuminated by three selected ultra-violet wave-lengths and the three images produced are electronically converted into images in three different colours on a television screen It is being used for examining ultra-violet radiation damage, the streaming of protoplasm and the absorption of metabolites such as vitamin A

A still wider range of application is open to the flying-spot technique, in which the specimen is explored point by point sequentially The source of illumination is the flying spot on the screen of an oscilloscope, which is demagnified through the microscope to throw a moving probe on the specimen The image is built up on a display tube, or the signal may be used directly for quantitative absorption measurements With suitable phosphors any part of the spectrum can be used, or indeed soft X-rays T O Caspersson (Karolinska Institutet, Stockholm) gave a masterly survey of the methods which can be used, and the factors influencing instrumental design, in the three main areas of investigation analysis of single cells or cell structures with high precision, analysis at lower accuracy of large numbers of cells or cell structures, and investigations on living material, which are often only possible by semi-quantitative or even qualitative methods He described a number of instruments in use, or in development, in his own laboratory for these different types of research, and discussed the choice between mechanical, optical and electronic systems of scanning

Most of the remaining contributions were variations on these themes J G Hoffman (University of Buffalo) described measurements of the nucleic acid content and the dimensions of mammalian cells and their nuclei, both by ultra-violet absorption in fresh cells and by absorption in the visible range in unfixed cells and in Feulgen-stained cells He discussed the use of a digital computer to facilitate analysis of the absorption measurements as they are obtained Britton Chance (Johnson Foundation for Medical Physics, Philadelphia) described investigations of respiratory enzymes by analysis of the fluorescence spectra excited in single cells J J Freed and J L Engle (Institute for Cancer Research, Fox Chase, Philadelphia) discussed the advantage of using a vibrating mirror to produce the scan, since it allows monochromatic illumination at any desired wave-length They described the instrument they have built for making repeated absorption measurements on single living cells It was found that continuous exposure of ascites tumour cells for 30 min at wave-lengths above 2400 Å produced no observable radiation damage, whereas at 2400 Å , or below, the typical radiation damage syndrome was observed

The chairman of the conference, P O'B Montgomery, who has been mainly responsible for pioneering flying-spot microscopy in the United States, described recent work in his laboratory (University of Texas Southwestern Medical School, Dallas) In addition to the development of a flying-spot interference microscope, he and his colleagues (W A Bonner and L L Hundley) have worked out techniques for simultaneous illumination of the specimen with both visible and ultra-violet light In one version of the apparatus, the two images appear side by side on the display tube Alternatively, a very small part of the specimen is imaged by ultra-violet while a larger field around it is imaged by visible light In this way the progress of ultra-violet radiation damage on selected cells, or even on different parts of a single cell, can be followed

One of the important uses of the flying-spot microscope is for counting and sizing particles, and instruments are commercially available for routine measurements of this type Attempts are now being made to extend the technique to the 'recognition' and counting of specific types of cells in tissue sections or smears, by applying to microscopy some of the experience gained in the use of radar for target spotting An instrument named the 'cytoanalyser' has been built for the mass screening of cervical and vaginal smears, to aid in the early diagnosis of cancer It is best described as an analogue-digital computer connected with an electromechanical scanning system, and is the fruit of collaboration between the Sloan-Kettering Institute for Cancer Research, New York, the American Cancer Society, the National Cancer Institute, and Airborne Instruments Laboratories of Deer Park, New York Its general principles of construction were described by W. E Tolles and H. P Mansberg of the last-named, and its functions and preliminary results of its operation by Elaine Diacumakos and Emerson Day of the first-named institution. The biological situation is complex, and it seems to be too early to judge how successfully the instrument can replace the human eye in spotting aberrant cells, and so dispensing with the squads of observers now employed in checking smears under the microscope In any event, these two papers were another striking illustration of the feeding back of experience from the field of war to the problems of peace

The remaining contribution, by V E Cosslett (Cavendish Laboratory, Cambridge), described the extension of flying-spot methods to the X-ray end of the spectrum, with some reference to the related technique of scanning electron microscopy Both have so far been mainly applied to metallurgical and mineralogical problems Very recently A D G Stewart (Engineering Laboratory, Cambridge) has built an ion gun into an electron scanning microscope, to produce etching of a specimen surface during continuous electron imaging It seems likely to be useful in studying the structure of teeth and other mineralized tissues, as well as of metals and alloys At the Cavendish Laboratory, an exploration is being made (with aid from the Medical Research Council) of the possible biological and medical applications of the X-ray scanning microscope—more accurately described as a microanalyser Some preliminary results were reported to the Conference, from the detection of foreign particles in lungs and other tissues to work on the mineralization of bone and teeth An appreciable proportion of iron (up to 7 per cent) has been found in the surface enamel of the incisors of a number of rodents. The technique has obvious uses in identifying dust particles in atmospheric pollution and related problems. The recent extension of its scope to the lighter elements, beryllium and carbon, makes an investigation of the possibilities of organic analysis desirable. However, it is doubtful if it can be of value in cytochemistry until the spatial resolving power is improved appreciably beyond the present limit of 0.25μ and the detection limit to better than one part in ten thousand.

The conference was throughout stimulating, and provoked much lively discussion, which often led back to fundamentals. It was the first meeting of its kind, and very much justified the initiative of the organizers. V. E. COSSLETT

TIME-RESOLVED SPECTROSCOPY

A CONFERENCE on "Spectroscopic Studies using Time-Resolved Techniques" was held in Manchester on June 16, under the auspices of the Institute of Physics and the Physical Society.

A brief introductory address was given by Prof. H. S. Lipson, president of the Manchester Literary and Philosophical Society, who welcomed members of the conference to the new rooms of the Society. He pointed out that the meeting was the first to be held there by the Institute of Physics and the Physical Society since these new buildings were completed, and which indeed had only been opened in September 1960.

The joint secretaries of the conference were Dr. L. Bovey, Atomic Energy Research Establishment, Harwell, and Dr. A. H. Gabriel, Atomic Weapons Research Establishment, Aldermaston. On the programme seven communications were listed and an eighth was added by Dr. C. Breton, who described some recent French work on plasma. As in other recent international conferences the scope of time-resolved spectroscopic work on plasmas, or indeed on discharges in general, has been shown to have extended very widely since the end of the Second World War, at which time very little work in this field had been done. This new work has, of course, largely been prompted by the rapidly growing interest in high-temperature plasmas, partly because of the widespread interest in the possibility of obtaining thermonuclear reactions and, more recently, partly because of work on the so-called magnetohydrodynamic conversion of energy. In both these closely related fields spectroscopic techniques are pre-eminent. This is because such techniques do not normally interfere with the discharge being investigated and because of their great range and power. The need for time-resolved studies, often on a sub-microsecond scale, has also led to the development of advanced optical techniques, and the latter were very much in evidence at the present conference.

Although speakers from France, the United States and South Africa all made contributions, the majority were provided by various workers from the Atomic Energy Authority at Harwell and Aldermaston.

The first paper was given by Dr. A. H. Gabriel, who has been responsible at the Atomic Weapons Research Establishment for the development of much striking optical apparatus for plasma work. He spoke about a system incorporating a fast-rotating mirror camera and a medium quartz spectrograph, used, for example, in work on fast pinched discharges with electron densities varying in the region 10^{15}–10^{18} per c.c. and lasting a few μsec. and time resolutions of the order of 0.1 μsec. or less. Dr. Gabriel then proceeded to describe various other optical techniques available, namely, an image-rotating device in which three mirrors are used with a vertical slit, and an apparatus for work in the vacuum ultra-violet region using near normal incidence and covering the wave-length range 2000–5000 Å. In such an instrument it was pointed out that astigmatism of the concave grating presents a difficulty. The spectrum is recorded near the base of the normal on to the Rowland circle and since only a limited wave-length range can be covered on one setting the position of the entrance slit assembly is made movable. A resolution of 3-mm. image displacement per μsec. is obtained. In connexion with all this work a precision capillary light source for calibration in the visible and quartz ultra-violet has been developed which gives virtually uniform illumination for about 12 μsec. and with an effective blackbody temperature of about 25,000°. Another source for vacuum ultra-violet work, based on that of W. R. S. Garton at the Imperial College of Science and Technology, was also described by Dr. Gabriel. Experiments at the Atomic Weapons Research Establishment that were mentioned include measurements of excitation temperatures, that is, state populations, etc., for various discharges, and studies of free-free continua in the temperature-range 10^5–2×10^6 degrees, and finally, Dr. Gabriel mentioned experiments involving observation of emission spectra of rapidly pinched discharges, for example, the influence of impurity lines at different times, and work on absorption spectroscopy using axial viewing from a hollow pinch in which electron densities could be obtained from a study of line widths.

The next speaker, Prof. J. D. Craggs of the University of Liverpool, described recent experiments on the measurement of line broadening due to the inhomogeneous field Stark effect in spark discharges (transient arcs). He briefly summarized the historical development of this technique, which is now widely used in plasma investigations, from the days when the statistical theory was considered adequate to the present time when a more accurate realization of the complexities of the effect, particularly with regard to the contribution made by electrons in the impact broadening process, has been reached. Recent experiments in Liverpool, notably by Dr. E. E. L. Mitchell, strongly support the recent theoretical work of Griem and Kolb in the United States. This is for the Balmer lines of hydrogen, but in view of the present importance of the impact broadening contribution of electrons, experiments have been carried out over the past two years in Liverpool by Mr. Lim, who has simultaneously studied sodium and argon lines (notably the former) broadened by the impact effect and the statistical-impact broadening of the Balmer lines. These results again support the Griem–Kolb theory and direct attention to the possibility of making electron density measurements with the use of impact-broadened lines The use of sodium–hydrogen discharges has led to a number of interesting excitation effects which are being studied and Prof Craggs briefly referred also to measurements of de-ionization of plasmas, with electron densities varying from about 10^{16} to 10^{18} per c c , in relation to the recent work of Prof D R Bates and Dr A E Kingston in Belfast and Dr R W P McWhirter in Harwell

Dr F D Harrington of the United States Naval Research Laboratory proceeded to describe a series of time-resolved spectrographs developed and used in recent years at that Laboratory. In particular the applications included investigations of exploding wires and high-velocity luminescent plasmas The instruments broadly fall into three general groups (*a*) the moving film type, (*b*) the rotating drum type, (*c*) the rotating mirror type Instruments in the first category are somewhat unusual in this respect, at least in European studies, and the technical excellence of the design and optical work was very apparent For example, Dr Harrington described an *f*6 6 ciné high-speed prismatic spectrograph for use in the near ultra-violet and visible region with film speeds of 9 ft /sec and 90 ft /sec giving respectively 460 and 4,600 frames/sec The resolving power was about 5 Å at a wave-length of 4000 Å with a dispersion of 125 Å /mm Another striking instrument described was a rotating drum continuous writing *f*/2 0 ultra-violet spectrograph Experiments were then described on exploding wire spectra for a time-range 0–10 µsec and using a 300-joule condenser discharge

Dr R Wilson of Harwell spoke on time-resolved intensity investigation of spectral lines emitted by impurity ions in *Zeta* hydrogen plasmas and concentrated on recent work on interpretation of these spectra rather than on the instruments involved The impurity lines were examined with monochromators covering the wave-length range 100–6000 Å and most of the work fell in the vacuum ultra-violet region where the strong lines of highly ionized ions occur Dr Wilson stressed that in a plasma of this type in which the electron density is of the order of 10^{14} per c c at an equivalent temperature of 20 eV , the dominant processes are ionization by electron collision and radiative recombination, as in the solar corona, and this meant a strong departure from thermal equilibrium Dr Wilson described recent experiments on the transient lifetime for spectral lines corresponding to successive studies of ionization and showed how these varied in a partially contained plasma Data were presented for the intensity transients of lines due to Ar I–Ar VIII The time duration of the optical transients for these different states increased up to Ar VI but thereafter remained constant, and similar results were described for O IV, O V and O VI Many new spectral lines, for example, due to Ne VII and Ne VIII, Kr V, Kr VI, Kr VII and Kr VIII and Xe V to Xe IX have been identified The containment times for many of these highly ionized states have been studied Thus, for example, in certain experiments Ar VIII was contained for about 450 µsec

Dr R V Williams of the Associated Electrical Industries Research Laboratories, Aldermaston, also described time-resolved spectroscopic work on toroidal plasma discharges such as those in the apparatus *Sceptre* 4 Dr Williams described the range of techniques available at the A E I Laboratories, including multi-channel recording with photomultipliers Experiments have recently been done on *Sceptre* 4 on radial variations of electron temperatures. for example, by studying the 2822 Å line of B IV which is concentrated near the centre of the discharge, and the 2066 Å line of B III was observed farther out, that is, nearer the tube wall These lines were excited when methane was added to the discharge in very small amounts, which are shown to have negligible effect on the overall properties of the discharge. Further radial work on the 2271 Å line of C V (C V is helium-like) were mentioned Various investigations of this kind indicated, for example, electron temperatures kT_e of the order of 20 eV Dr Williams also mentioned in this connexion new work in progress on F V and F VI lines which is being carried out again to obtain electron temperatures Plasma instabilities are being detected spectroscopically by examining high-frequency intensity fluctuations in spectral lines, the frequencies involved lie in the range 10–100 kc /sec and instabilities occurring in different parts of the discharge could be separately detected by observing lines from ions having varying ionization potentials For example, the 2781 Å line of O V was used for examining instabilities near the centre of the discharge and the second Balmer line (D_β) for instabilities occurring near the wall of the containing torus Further experiments involving the use of two monochromators so placed that each gave one of a pair of oscillograms of a single line, have given some support to recent theoretical treatments of plasma instabilities which indicate that the latter should be propagated in a torus with velocities depending on the magnetic field and the plasma pressure, the measured velocities of such instabilities agreeing quite well Predicted values were about 10^6 cm /sec

Dr N J Peacock of the Atomic Weapons Research Establishment Plasma Group at Aldermaston described spectroscopic work on the fast pinch discharges at that establishment The experiments involve rapidly rising axial magnetic fields, electron densities of the order 10^{16} or 10^{17} per c c and electron temperatures estimated, for example, from measurements of the continuum established in the wave-length region below 20 Å as 100 eV or higher Time-resolved spectrograms provide evidence in support of other work with streak cameras and with X-ray and neutron emission studies when maximum temperatures are reached during the second half-cycle of the driving field Time-resolved spectrograms have enabled temporal variations of electron density, ion and electron temperatures and plasma distribution to be made on helium discharges and other discharges including a few per cent of added impurities Studies of Stark-broadened profiles of the He II line 4686 Å agree well with Griem's theoretical work Time-resolved spectroscopic work on electron temperature and electron density taken for various radial positions in the tube enable diffusion-rates of the plasma through the containing field to be estimated Dr Peacock also described emission work on deuterium–oxygen discharges, for example, in which energy balance relations have been studied In this work electron temperatures have been estimated from the ratios of intensities of He I and He II lines and in various other ways Dr Peacock showed interesting space-resolved spectra for helium and temporal variations of ion density across the discharge showing a shell structure

Mr W W. Schroeder of the National Physical Research Laboratory, Council for Scientific and Industrial Research, Pretoria, described recent developments in photo-electric recording of spectra from transient sparks The techniques have been developed specifically to improve time-resolved spectroscopic analysis of solids, for example, the quantitative detection of copper in aluminium alloys The controlled gating of the photo-multiplier proved to be so good that special controlled spark sources had to be developed and a description of such a source was given based on the work of A Bardocz in Hungary This source used an air-blasted control gap in series with the test gap The jitter proved to be not more than 15 mµsec over 10^7 discharges, and the importance of ultra-violet illumination of the test gap by the control gap was shown to be important

It was possible to analyse a spectral line with a resolving time of 0 1 µsec The speaker stressed that in spectroscopic analysis of this kind time-resolved observations might well be of importance in the investigation of analysis and internal standard lines, etc

Dr. C Breton (Fontenay-aux-Roses) gave an account of spectroscopic observations made in that establishment, including the observation of impurity lines in the far ultra-violet in a toroidal discharge and a new technique for the study of line profiles The former work was carried out with a vacuum grating spectrograph using seven exit slits, each with a separate photomultiplier tube Impurity lines from carbon, oxygen and nitrogen ions were observed with a 20 kV. 200 microfarad capacity bank feeding toroidal discharges at a pressure of 10^{-3} mm of mercury Dr Breton described a new and interesting technique in which a broadened line profile is divided into thin slices by the use of successive layers of glass fibres some 50µ in diameter to centres of spaces approximately 55µ apart The assembly is used in a 1-m. focal distance monochromator giving an average dispersion of about 3 Å /mm in the first order and in the visible region Each fibre corresponds to an interval of about 0 15 Å and Dr Breton showed curves giving temporal variations of the profile of H_β, finally, he mentioned experiments on plasma radiation and the drift velocity of ions in a magnetic mirror machine.

J D Craggs

ELECTRON SPIN RESONANCE

On November 2 the Chemical Society held a symposium at Queen Mary College, London, on electron spin resonance In the first part of the symposium there were three papers In an introductory paper, Prof H C Longuet-Higgins outlined the principles of electron spin resonance measurements Only paramagnetic substances show this phenomenon, which arises from their unpaired electrons In a magnetic field the two spin states of a single electron are split apart in energy by virtue of the magnetic moment of the electron An oscillating magnetic field, applied at right angles to the permanent field, causes the electron to jump from one of these levels to the other if the frequency ν of the oscillating field satisfies the relationship

$$h\nu = g\,\beta H, \quad \beta = eh/4\pi mc$$

Here H is the strength of the permanent field and g is a number which equals 2·0023 for a free electron Electron spin resonance measurements acquire their interest from two subsidiary physical effects The first of these is the so-called hyperfine interaction, which arises when the paramagnetic molecule includes magnetic nuclei The value of g then depends on the orientation of all the magnetic nuclei, and a series of lines is observed rather than a single resonance As an example, n equivalent protons will give rise to $n + 1$ hyperfine lines with a binomial distribution of intensity, a single nucleus of spin I (which may be $\frac{1}{2}$, 1, $\frac{3}{2}$, etc) will give a set of $2I + 1$ equally spaced lines of equal intensity The foregoing remarks apply to a paramagnetic molecule tumbling over and over in the liquid phase But if the molecule is fixed in the external magnetic field, the spectrum may be more complicated because of direction-dependent interactions between the electron and the magnetic nuclei The directional variation of the spectrum may then enable one to identify the orbital in which the odd electron is moving

The other physical effect which provides useful information about the nature of the unpaired electrons is spin-orbit coupling An electron with orbital angular momentum is easier to orientate in some directions than in others, and this means that g must be regarded not as a pure number but as a tensor The axes of the g tensor must coincide with the symmetry axes of the molecule. and certain applications of this fact would be discussed later in the symposium

The next paper, by Prof S I Weissman, was concerned with line-widths in electron resonance spectra The width of a line is inversely proportional to the mean life-time of the spin states involved in the transition Measurements of line-broadening can therefore throw light on the rate at which electrons are transferred from one molecule to another (assuming this to be the process which determines the life-time) Prof Weissman gave some examples, including the reaction of the naphthalene molecule with its negative molecule ion and the exchange of a sodium ion between two naphthalene molecule ions As he pointed out, an electron resonance spectrum always supplies kinetic information, whether one is interested in it or not

The third paper, by Prof D J E Ingram, was concerned with the structural information which is provided by electron resonance measurements on single crystals Prof Ingram classified this information under three headings measurements on the g tensor, studies of the hyperfine structure and measurements of electronic splittings (sometimes called zero-field splittings) At Southampton he and his colleagues had determined the orientation of the hæm in groups in myoglobin and hæmoglobin by examining the way in which g varies when the crystal is rotated in the externally applied magnetic field In this particular case there is a very large variation in g, from 2 to 6, so that the orientation of the hæms can be very accurately determined In myoglobin there are two hæms per unit cell and their orientation as determined in this way was afterwards confirmed by the X-ray work of J C Kendrew An interesting molecule is hæmoglobin azide, where the g

tensor is completely anisotropic. J. S. Griffith had been able to determine from this tensor the order and spacing of the 3*d* orbitals on the iron atom; this order indicates very strongly that the histidine group attached to the iron atom is in a plane parallel to one of the diagonals of the hæm plane.

Information can also be obtained from the hyperfine splittings produced by protons or other magnetic nuclei. These splittings can be correlated with the types of group that are present and the angles which they make with one another. In order to extract such information from the data, one must, however, make use of molecular orbital theory, and the same applies to the sort of information which can be obtained from measurements of zero-field splittings.

In the second section of the symposium, four papers were presented.

The first paper, by J. R. Bolton and A. Carrington, was concerned with two topics. The first was the measurement and interpretation of the electron spin resonance spectra of the negative ions of toluene, *p*-xylene and *m*-xylene. These are of special interest because of the degeneracy of the lowest antibonding orbitals of benzene. This degeneracy is removed by introducing methyl groups, and one can predict from the molecular orbital theory which of the two orbitals is likely to be occupied in the ground-state of each ion. The spectra of these xylenes, and of their partially deuterated isotopes, completely confirm the theoretical predictions, and in particular the hypothesis that the methyl groups repel the additional electron.

The other topic discussed by Dr. Carrington was certain remarkable line-width alternation effects which occur in the electron spin resonance spectra of the durosemiquinone positive ion and in the positive ion of 5,8-dihydroxy-1,4-naphthasemiquinone. This effect is almost certainly due to *cis-trans* isomerization proceeding at a rate comparable with the separation (in cycles/sec.) between the hyperfine lines in the resonance spectra. Dr. Carrington also directed attention to the possibility of determining the signs of hyperfine interaction constants by studying the variation of line width as one proceeds from one end of a spectrum to the other.

In the next paper Dr. E. A. C. Lucken described experiments on various substituted *p*-benzosemiquinones and polynuclear aromatic quinones. He used these measurements in attempting to evaluate coulomb integrals and resonance integrals for the various types of atoms and bonds. These attempts were not altogether successful, but Dr. Lucken claimed that his experiments could be interpreted by supposing that the methyl group produced an inductive effect, but did not enter into hyperconjugation. In the subsequent discussion, Dr. Carrington said that he, J. R. Bolton and A. D. McLachlan had obtained strong evidence for hyperconjugation—at least in hydrocarbon cations—from experiments on the positive and negative ions of anthracene and its 9-methyl and 9,10-dimethyl derivatives.

Prof. M. C. R. Symons then gave a lecture on the use of electron resonance in identifying the products of radiation damage in some inorganic oxy-salts. As Prof. Symons pointed out, such work can provide interesting information about the closed-shell species from which the paramagnetic radicals or radical ions are derived. He illustrated this remark with reference to the manganate and hypomanganate ions which result from the addition of one or two electrons to MnO_4^-. Work on damaged crystals is, however, often complicated by the difficulty of identifying the products, especially if the common isotopes of the nuclei have no magnetic moment. Nevertheless, in some cases it may be possible to argue by analogy, as in the series ClO_3, SO_3^-, PO_3^{--}. Prof. Symons described some preliminary work on the oxyions of chlorine, nitrogen and sulphur, and offered an explanation for some apparent discrepancies between the results of various authors who had studied the NO_2 molecule in different environments.

The final paper in the symposium was given by J. R. Morton. When a crystal of L-alanine is irradiated with γ-rays the radical CH_3CHCO_2H is produced. The electron spin resonance spectrum of this radical shows hyperfine structure which varies with the orientation of the crystal and also changes markedly when the crystal is cooled to 77° K. It is possible to analyse this spectrum fully and to obtain the hyperfine coupling tensors for the CH proton and the three protons of the CH_3 group. The radical is found to be planar, with a CH_3—C—H angle of 121 ± 3°. The spectra at 77° K. indicate that the methyl group has ceased to rotate at that temperature, and an estimate of the height of the rotation barrier can be obtained from the spectra at intermediate temperatures.

At the end of the meeting Dr. D. H. Whiffen proposed a vote of thanks to Prof. K. W. Sykes for arranging the symposium and to Queen Mary College, London, for generous hospitality.

H. C. LONGUET-HIGGINS

THE HEALTH OF SEAFARERS

THE total number of seafarers on ships other than those engaged in coastal trading is in the region of 750,000. They form a definite community the members of which are linked together by mutual interest—and health hazards—at least as closely linked as they are to their parent countries. Although much has already been done to improve their working conditions and health standards, much remains to be done. In 1959 the World Health Organization undertook a study of the whole problem of the health of seafarers. As a preliminary fact-finding step, the World Health Organization Regional Office for Europe convened a conference at which it became clear that not enough was known of the health problems of seafarers or of the health services available to them. Following this conference, a questionnaire was drawn up by the Organization in consultation with the International Labour Organization and circulated to member States. The next step was to appoint a consultant to visit some of the major ports to analyse the problem in those ports where services were already in being and to supplement, where necessary, the information given in replies to the questionnaire. The ports visited were Liverpool, London, Marseilles, Athens, Alexandria, Bombay, Singapore, Manila, Hong Kong, Tokyo, San Francisco, Montreal, Helsinki, Gothenburg and Hamburg The findings of this investigation were reported to a Joint Committee on the Hygiene of Seafarers, set up by the two Organizations, that met in Geneva during May 1–4, and are reported in a recent issue of the *WHO Chronicle* (**15**, No 10, October 1961).

There seems to be general agreement that certain complaints occur more often than others, such as diseases of the gastro-intestinal tract, cardiovascular diseases, skin diseases, mental disorders, venereal diseases, tuberculosis and dental complaints The accident-rate is high. Owing to the lack of comparative morbidity statistics it is difficult to ascertain whether accidents and these diseases occur more frequently among seamen than among male groups with the same age distribution in the general population. There is also some national bias in disease incidence Venereal disease and tuberculosis remain common causes of incapacity in some of the developing countries, whereas mental disorders are more common in some of the developed countries There is little information about the number of deaths occurring among seafarers, but accidents seem to be the commonest cause, accounting for more than 50 per cent of all deaths in the merchant service in some countries

In certain countries there are no special hospital or clinic facilities at all for seafarers ashore In these countries seafarers are referred to the general hospital or private medical care facilities available to the public In the United Kingdom, Norway and Sweden, there are a few special clinics and hospitals based on some major ports and organized by the shipping companies and local authorities acting separately or in conjunction Finally, there are a few countries which provide free medical care for seafarers as a special class, in the United States and Canada through the public health service, in Israel by a private company, in Japan by the Seamen's Insurance Association In all cases, continuity of treatment from port to port or port to ship is poor

Some Governments have no definite regulations regarding the provision of a ship's doctor Most stipulate a physician if there are more than 100 persons aboard, and many a nurse or nurses also if passengers and crew exceed a given number A few countries require a doctor for less than 100 persons When, for any reason, no physician is available, medical care is provided by the master or chief officer, occasionally by another designated officer or by a nurse, in many countries the responsible individual is given special training for the work, though such training is not always of a high standard The ships of most countries must carry a medical guide and a medical chest, but the standards of equipment and inspection are sometimes inadequate Some States have no form of health insurance, either for the general public or the seafarer, in others, health insurance is included in a comprehensive scheme In some cases there are special compulsory arrangements for seafarers

Despite the defects reported and the apparent chaos of national regulations and facilities, much has been done to ensure certain minimum standards A great deal of useful work is done by the Red Cross and other voluntary bodies and by the shipping industry itself

Several conventions and recommendations concerning the health of seafarers have been established by the International Labour Organization These deal with medical examinations, medicine chests, medical advice by radio at sea, social security and sickness insurance, and can be extremely helpful to countries developing their health services for seafarers Not all these conventions and recommendations have been universally adopted, or fully implemented where they have been adopted

A good deal can be done towards the prevention of injuries and disease on board ship Attention to design and to lighting at strategic points will help to limit accidents, instruction in the composition and preparation of food is important to prevent gastro-intestinal disease, and periodic medical reviews have their place in the prophylaxis of mental illness, dental disease, venereal disease and tuberculosis The development of a system to produce reliable statistical data to fill existing gaps in the morbidity and mortality statistics on seafarers would be helpful in deciding what type of medical organization should be set up for them on an international basis

There is also the question of hazards on nuclear-powered ships Few of these vessels are in commission at present, but there will be many more The point at issue is not the danger to the public from a major accident, but the specific risks to the crew It is essential to have a skilled man acting as radioactivity monitor, and protective clothing should be available for all crews Periodic examinations for signs of radiation sickness are as necessary as at nuclear plants ashore All nuclear-powered ships should be clearly marked so as to be easily identifiable in case of collision or other accident

EFFECT OF MECHANICAL STRESS ON SOME SOLID-STATE POLYMERIZATIONS

By DR. C H. BAMFORD, DR G C EASTMOND and DR J. C WARD

Research Laboratory, Courtaulds, Ltd., Maidenhead, Berks

FOR some time workers in the field of free-radical reactions in the solid state have suspected that an important part of any mechanism will involve crystal imperfections and annealing processes[1-4] In this case it might be expected that mechanical stresses would exert a noticeable effect on the course of the reaction According to Adler's views[1,2], based on different considerations, a compressive stress would lead to an increase in the rate of reaction, since it would tend to reduce the strain-energy at the monomer–polymer interface[1], polymerization usually being associated with a decrease in volume

We have been examining the polymerization of crystalline acrylic and methacrylic acids (m p 12 5° C and 16° C respectively), initiated by ultra-violet light, and hope to report on recent work shortly. The purpose of this communication is to record some novel observations.

The specimens used were in the form of thin layers of non-overlapping crystals, approximately 10μ thick, formed by allowing degassed monomer to freeze in the narrow gap between a flat silica disk and a glass microscope coverslip. The monomer samples had a water content of less than 0·02 per cent. The crystals were formed and contained in a cell fitted with a quartz window and with provision for evacuation and cooling. By the compression of springs suitably located within the cell an even mechanical pressure of about 50 lb./sq. in. could be applied normal to the layer of crystals, at any stage of the reaction, without disturbing the sealing of the cell. The specimens were irradiated by ultra-violet light from a high-pressure mercury lamp, the cell being situated in a thermostat tank at 4° C.

The course of the reaction was followed by observing the crystal birefringence, which decreased during irradiation. A plot of birefringence against time was sigmoid in shape, showing marked autocatalysis for both monomers. No effects other than the decrease in birefringence were observed, at least in the early stages of reaction. The occurrence of polymerization was confirmed by raising the temperature above the melting point of the monomer, when polymeric pseudomorphs of the original crystals could be seen.

In the absence of pressure extensive polymerization of crystalline acrylic acid, indicated by a complete loss of birefringence and absence of liquid formation on warming, was achieved after 10 hr. irradiation. In otherwise identical experiments in which the compressive stress was applied throughout, only a trace of polymer was formed after 20 hr. irradiation, further, observation of the birefringence during this time showed a small decrease in the initial stage with no subsequent change throughout the time of irradiation (Fig. 1, curve *a*).

Fig. 1, curve *b*, shows the effect of application of stress during irradiation. The crystals of acrylic acid had been irradiated without stress for 5 hr., application of compressive stress then caused complete cessation in the decay of birefringence. When this stress was afterwards removed the reaction started again, being preceded by an induction period similar to that observed initially.

Methacrylic acid crystals behaved in an analogous way, with differences in detail. When pressure was applied at the beginning of irradiation the course of the reaction followed that without pressure for about 4 hr., but the rate of decay of birefringence then declined and complete loss of birefringence was only achieved after a period of irradiation exceeding 24 hr. In the absence of pressure complete conversion is attained in a much shorter time (Fig. 2, curve *a*).

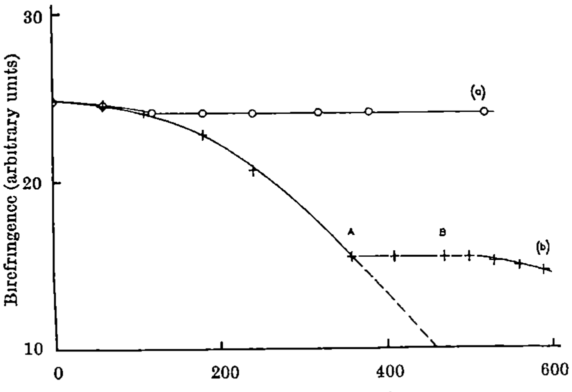

Fig. 1. Polymerization of acrylic acid crystals at 4° C. in ultra-violet radiation. (*a*) Stress applied throughout period of irradiation, (*b*) stress applied at *A*, released at *B*, ---, normal course of reaction without stress

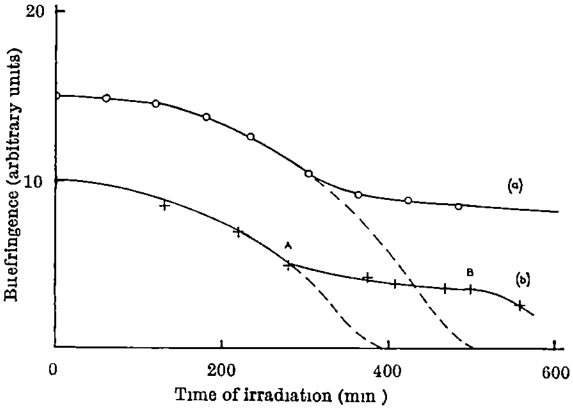

Fig. 2. Polymerization of methacrylic acid crystals at 4° C. in ultra-violet radiation. (*a*) Stress applied throughout period of irradiation, (*b*) stress applied at *A*, released at *B*, ---, normal course of reaction without stress

Application of stress to methacrylic acid crystals during irradiation, at a conversion of about 50 per cent, caused a marked and progressive reduction in the rate of loss of birefringence (Fig. 2, curve *b*), which eventually fell to an extremely small value. Removal of the stress produced an immediate acceleration. There was some indication that the effect of pressure was anisotropic, different crystal aspects being affected to different extents.

These results show that mechanical stress can have a large effect on the photopolymerization of crystals of these acids. The pressures used in this work are relatively very small—about two orders of magnitude less than those required to affect some solid-state phenomena[5]. In this connexion it is relevant to note that the reaction temperature was not far removed from the melting points, acrylic acid, which shows the greatest effect of pressure, was 8·5 deg. C. below the melting point, compared with 12 deg. C. for methacrylic acid. Further, it is apparently necessary for some polymer to be formed before the sensitivity to pressure is developed.

There appear to be three main types of explanation which can be advanced to account for these results. First, a macroscopic second phase—liquid or vapour—may be necessary for polymerization, for example, situated initially between the crystal and the boundary surface, this could be removed by the application of pressure, which might 'squeeze out' the second phase, or cause it to freeze. When the specimens were prepared the liquid was seen to freeze completely, the crystals growing in contact with both boundary surfaces, and no evidence for the existence of such a second phase was ever observed. Further, the effect of pressure on the freezing points of these acids is small, of the order of 1 deg. C. for 100 atm. Secondly, the pressure might remove imperfections, for example dislocations, which are the sites of initiation and propagation. This process might be considered as a sub-microscopic analogue of that described here and would reduce the mobility of the molecules below the limiting value required for polymerization. Either of the above explanations would imply that polymerization occurs in regions where there are discontinuities in preference to the perfect lattice Thirdly, one might suppose that applied stress produces (rather than destroys) imperfections[5], which trap propagating radicals and reduce the rate of polymerization However, the polymer produced itself constitutes an imperfection in the crystal, and since the reaction is autocatalytic one might argue that, in fact, imperfections facilitate the reaction

SPECIFIC PARTIAL HYDROLYSIS OF NUCLEIC ACIDS IN NUCLEOTIDE SEQUENCE STUDIES

By DR. D W VERWOERD, DR. H KOHLHAGE and DR. W. ZILLIG
Max Planck Institute for Biochemistry, Munich

THE specific partial hydrolysis of the nucleic acid chain is one of the main problems confronting the investigator working on the sequential analysis of the nucleotides in nucleic acids A method for the stepwise degradation of the chain, proceeding from one end and combining enzymatic and chemical procedures, has been developed by Whitfeld[1] and was recently improved by Zamecnik[2] and Cohn[3] Though it can be applied successfully to end-group analysis or to the analysis of short-chain fragments, the method has the same disadvantages as purely enzymatic procedures, namely, insufficient specificity and non-quantitative yields These factors impose a limit of a few sequences

Up to the present, only methods of enzymatic nature have been available for the specific partial hydrolysis of the nucleic acid chain, such as treatment with pancreatic ribonuclease (RNase) and with the ribonucleases specific for adenylic and guanylic acids isolated by Egami[4] We therefore investigated the possibility of modifying nucleic acids by chemical means in order either to achieve a chemical hydrolysis or to modify the known enzymatic degradations Chemical hydrolysis would be made possible if the β-elimination principle described by Linstead[5] could be applied Modification of the mode of action of pancreatic RNase would result if either of the two main pyrimidine bases in ribonucleic acid (RNA) could be removed or changed in such a way that RNase would no longer attack the adjacent 3″-phosphodiester bonds

By this approach one would expect to obtain optimally three or four different hydrolytic procedures yielding fragments of rather small length with overlapping sequences Since nucleic acid chains, often consisting of thousands of nucleotides, contain virtually only four different bases, it would, however, still be impossible to reconstitute the full sequence of a long chain, unless additional methods are devised for obtaining larger fragments

With this in mind we have investigated the reaction of hydrazine and hydroxylamine with RNA and its constituents

Levine and Bass[6] first described the reaction of hydrazine with pyrimidine nucleotides They demonstrated a splitting of the ring in uridylic acid with the formation of free pyrazolone and a urea residue attached to the ribose Witzel[7] used this reaction to prepare nucleoside 5′-phosphates from dinucleoside monophosphates containing uridine 3′-phosphate by degrading the uracil, removing the urea residue by weak acid hydrolysis and cleaving the resulting β-carbonyl phosphoric ester by alkaline hydrolysis

In a kinetic examination of the reaction of hydrazine with the four common nucleotides of RNA at different *p*H values and temperatures, we found, however, that it attacks both uridylic and cytidylic acids to such an extent that it is impossible to obtain a sufficiently specific degradation of either of them.

The work of H Schuster on inactivation by hydroxylamine of biologically active nucleic acids turned our attention to this reagent, which has recently been used extensively as a mutagenic agent[8,9] Preliminary investigations of the reaction kinetics in our laboratory soon proved the superiority of hydroxylamine to hydrazine for our purpose

A salt-free aqueous solution of hydroxylamine in concentrations of 3–10 molar was incubated at different temperatures and *p*H values with the common nucleotides, nucleosides and corresponding bases Reaction-rates were followed spectrophotometrically after electrophoretic separation of the reaction products No reaction was found in the case of adenine and its derivatives, whereas those of guanine and thymine reacted only very slowly under our experimental conditions

Both uracil and cytosine nucleotides and nucleosides are attacked, but the free bases react much more slowly The dependence on *p*H of the reaction-rates of the groups differ appreciably The *p*H optimum for the reaction with uridylic acid lies at *p*H 10 1, whereas that for cytidylic acid is 6 1 Fig 1 gives the reaction-rates, as measured by percentage of

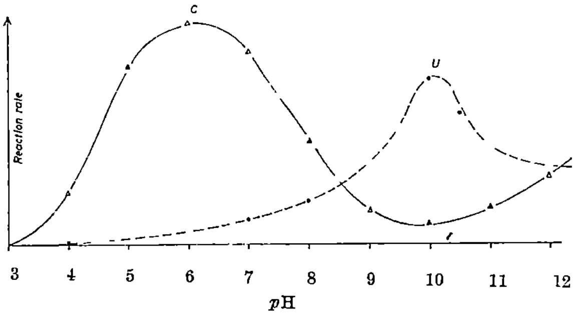

Fig 1 Dependance of rate of reaction of 6 *M* aqueous hydroxylamine with 2′,3′-uridylic acid (U) and 2′,3′-cytidylic acid (C) Reaction-rate measured as percentage of decrease of extinction in 10 min during the initial reaction phase

decrease of extinction during a 10-min interval in the linear phase of the reaction, as a function of the *p*H.

This curve clearly indicates a possibility of degrading cytidylic acid or uridylic acid selectively by controlling the *p*H. This possibility is, however, limited at *p*H 10·0, where cytidylic acid still reacts to some extent. Furthermore, when applied to nucleic acids, this *p*H leads to a slow alkaline hydrolysis of the chain of about 1 per cent per hr. In order to investigate the possibility of increasing the specificity of the reaction, and to evaluate the extent to which RNase action would be modified, an investigation of the chemical nature of the reaction and the reaction products was conducted.

Reaction of Uridylic acid and Uridine with Hydroxylamine

The rate of the reaction is directly proportional to the concentration of hydroxylamine in the range of concentrations investigated. Under our conditions, the reaction kinetics corresponded to those of a pseudo first-order reaction. Products of the reaction were separated electrophoretically and consisted mainly of urea, ribose oxime or its phosphate and an unknown substance with strong ultra-violet absorption. Urea and ribose oxime were identified by comparing the chromatographic and electrophoretic behaviour with standards. The other product was identified as isoxazolone-5, a substance of which only derivatives were known hitherto. Its structure is based on the following data. The electrophoretic mobility and potentiometric titration curve indicate an acid with *pK* near 3·4. The substance is stable only in the anionic form and decomposes rapidly in acid to form a variety of products, among others a hydroxamic acid. The ultra-violet spectrum is in agreement with the proposed structure, with an absorption peak at 247 mμ and a specific extinction of 7·9 × 10^{-3} at *p*H 13·0. Catalytic hydrogenation with Raney nickel or platinum ($Pt[H_2]$) yields β-alanine, ruling out the possible alternative configuration of isoxazolone-3, which would have given β-hydroxypropionic acid amide. Finally, the substance was synthesized from both[1] the sodium salt and the oxime of formyl acetic ester and from propiolic acid ethyl ester by reaction with hydroxylamine (Fig. 2).

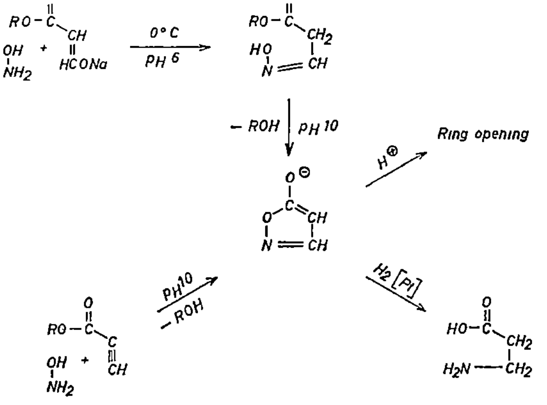

Fig. 2. Synthesis and reactions of isoxazolone-5

The synthetic product was identical in electrophoretic behaviour to the uridylic acid derivative; it also yielded β-alanine on hydrogenation and the acid breakdown products from both were chromatographically identical in four different solvent systems.

The reaction can be formulated in terms of a nucleophylic attack by the hydroxylamine nitrogen on the electrophylic C(4), or by the oxygen on C(6), followed by a cyclization and the formation of isoxazolone-5 and elimination of urea riboside or its phosphate from which the urea is displaced by another molecule of hydroxylamine (Fig. 3).

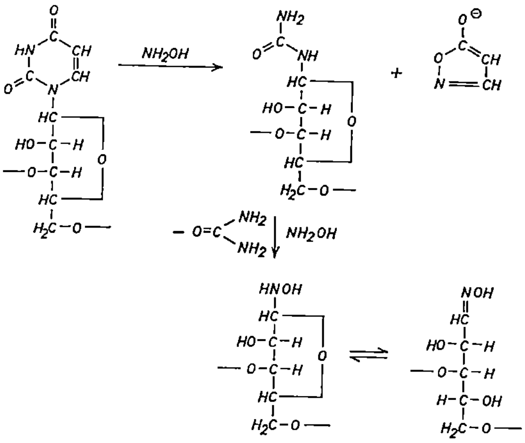

Fig. 3. Reaction of hydroxylamine with uridine and uridylic acid

The substitution of the N(3) atom in nucleosides and nucleotides would weaken its basic character, thereby increasing the susceptibility of C(4) or (6) to nucleophilic attack. This would explain why uracil reacts only very slowly. The slow-down of the reaction above *p*H 10·0 is probably due to the dissociation of the first hydroxyl group of uracil at *p*H 9·5. In the case of isocytosine, where the basicity of the ring is decreased, the rate of reaction with hydroxylamine is accelerated to such an extent that the free base reacts comparably to uridylic acid, also yielding isoxazolone-5.

Reaction of Cytidylic acid and Cytidine with Hydroxylamine

The ultra-violet extinction of cytidylic acid is obliterated within 90 min by treatment with hydroxylamine at the optimum *p*H of 6·0. Electrophoretic separation of this mixture at *p*H 3·5, however, yields mainly a strong ultra-violet absorbing band with a mobility between that of guanylic and uridylic acids. This substance was isolated by preparative electrophoresis on a 'Sephadex' block, purified on a 'Dowex-50' column, crystallized and identified as uridylic acid-6-oxime. The ultra-violet spectrum corresponds to that obtained by Fox and Bendich[10], being similar to that of cytidylic acid in the acid region with a peak at 278 mμ, which disappears at neutral *p*H. Electrophoretic mobility indicates a compound with a negative charge between that of uridylic and cytidylic acids at *p*H 3·5 and containing ribose and phosphate. On hydrolysis in 1 *N* hydrochloric acid for 1 hr at 100° C., the substance yields uridylic acid, which was identified by electrophoretic and chromatographic comparison with a reference, as well as hydroxylamine. The uridylic acid 6-oxime was found to be relatively stable, being hydrolysed only very slowly in acid or alkali at 37° C.

The initial disappearance of the ultra-violet extinction at *p*H 6·0 indicated that the uridylic acid 6-oxime was a secondary product and that some intermediate is involved This intermediate was partially purified by electrophoresis at *p*H 6 0 and could be converted quantitatively into uridylic acid 6-oxime by incubating in *N*/10 hydrochloric acid in a boiling water-bath for a few minutes Bautz and Freese[11] also recently observed this reappearance of the ultra-violet extinction after hydroxylamine treatment of cytidylic acid, but thought it was due to reconversion to cytidylic acid itself

In the presence of an excess of hydroxylamine the intermediate is degraded at *p*H values above neutral, possibly by a similar mechanism to that of uridylic acid breakdown, because two identical end products giving a positive hydroxamic acid reaction with ferric chloride reagent are found No equivalent heterocyclic intermediate could, however, be isolated An analysis of the intermediate yielded a nitrogen/phosphorus ratio of 3 93 1 An assumption that hydroxylamine was added to the 1,6 double bond of cytidylic acid yielding 6-hydroximino-1,6-dihydrocytidylic acid, could explain the spectrophotometric observations and was apparently supported by the demonstration of ammonia, later found to be a contaminant, in the acid degradation product It was not, however, in accordance with the Pullmans' calculation that the C(4) would be the most reactive centre in this reaction[12], and neither could it explain the anomaly between the reaction of hydroxylamine with cytidine monophosphate and with RNA (see below)

Evidence was obtained by Brown[13] that two molecules of hydroxylamine take part in the reaction and that the 4,5 double bond disappears This indicated a two-stage reaction with an initial addition of hydroxylamine to the double bond followed by substitution of the amino group by a second molecule of hydroxylamine Further supporting evidence for this hypothesis was obtained in our laboratory by demonstrating electrophoretically the formation of ammonia in the reaction yielding the intermediate, and of free hydroxylamine during the conversion of intermediate to oxime The reactions described are summarized in Fig 4

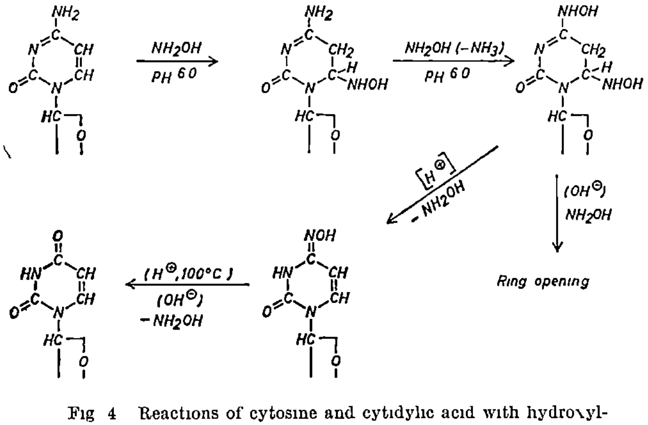

Fig 4 Reactions of cytosine and cytidylic acid with hydroxylamine

Application of the Hydroxylamine Reaction to RNA

Preliminary results indicating the applicability of the reaction to nucleic acids can be reported Experiments were performed on ribosomal ribonucleic acid from *Escherichia coli*, under strict *p*H control at *p*H 10 and 6 with 6 *M* hydroxylamine at 37° C After completion of the reaction, the RNA was precipitated with perchloric acid and parallel samples hydrolysed in alkali and pancreatic ribonuclease respectively Mono- and oligo-nucleotides were separated electrophoretically on 'Sephadex *G* 75'

At both *p*H values the overall reaction-rate was slower with RNA than with mononucleotides, probably due to the secondary structure of the RNA The specificity remains the same, mainly the uridylic acid residue being degraded at *p*H 10, although a certain amount of cytidylic acid breakdown also occurs In the RNase hydrolysate after *p*H 10 treatment, virtually all the uracil monophosphate disappears That RNase does not hydrolyse the chain at the sites where uracil has been removed is more conclusively shown by the marked decrease of cytidine monophosphate as well as of oligonucleotides with electrophoretic mobilities near those with uridylic acid end-groups in untreated RNA hydrolysates During incubation at *p*H 10 for 3 hr , about 5 per cent of the RNA becomes soluble in acid, indicating non-specific alkaline hydrolysis and possibly some hydrolysis caused by a β-elimination reaction

At *p*H 6 0 essentially comparable results were obtained, oligonucleotides with cytidine monophosphate end-groups diminishing markedly and cytidine monophosphate disappearing from the hydrolysate The alkaline hydrolysate of the same material showed no decrease in cytidine monophosphate content, however This can be explained by assuming that secondary structure bonding permits only the addition of the first hydroxylamine molecule to the 4,5 double bond of the uracil residue, thereby changing its aromatic character and inhibiting the RNase action The first-stage intermediate thus formed is then reconverted to cytidylic acid during the alkaline incubation This reconversion could not be obtained with mononucleotides, indicating that the second stage of the reaction, the substitution at C(6), is irreversible

The results of this investigation indicate that it is possible to modify nucleic acids by chemical means in such a way that a defined enzymic partial hydrolysis different from, and of higher specificity than, that obtained without the treatment becomes feasible

The foundation for the development of a chemical partial hydrolysis procedure on the β-elimination principle has also been laid This could be achieved, for example, by adding a suitable amine during the reaction of nucleic acid and hydroxylamine at *p*H 10

The specificity of the reaction, especially at *p*H 10 0, must still be improved The investigation of the reaction of hydroxylamine with nucleic acid, and the possible ways of effecting partial hydrolysis of the product, has only started and is being continued

We acknowledge the support and interest of Prof A Butenandt, in whose laboratory this work was performed Thanks are due to Dr H Schuster for stimulating discussions

FERROMAGNETIC INCLUSIONS IN NUCLEIC ACID SAMPLES

By W. M WALSH, jun., R. G. SHULMAN* and R. D. HEIDENREICH
Bell Telephone Laboratories, Inc , Murray Hill, New Jersey

BROAD, occasionally very intense, magnetic resonance absorption signals have been observed in a wide variety of preparations of nucleic acids[1-4] The origin of these signals has not been specified, though it has been inferred that large numbers of unpaired electron spins (as many as 10^{21} spins/gm in some cases) are inherently present in these and certain other organic structures of high molecular weight A critical point in these arguments has been the purported absence of inorganic, magnetic impurities in quantities sufficient to explain the observed resonance intensities

Recently it has been found that samples yielding electron-spin resonance spectra similar to certain of those reported earlier exhibit *ferromagnetic* rather than *paramagnetic* behaviour[5] The possibility that the resonance depends critically on the existence of a polymeric organic structure has been disproved since denaturation of deoxyribonucleic acid (DNA)[4] or even heating well above the charring point does not destroy the electron-spin resonance signal[6] Furthermore, trace quantities of iron, the dominant iron-group impurity, have been found in amounts sufficient to explain the observed magnetism if it is assumed that the magnetic ions are present as concentrated ferromagnetic aggregates rather than as disperse paramagnetic centres[5,6] We now wish to summarize a series of subsequent experiments which confirm this hypothesis and which permit a good guess as to the specific iron compound involved as well as its origin

The generality of the phenomenon has been established by examination of a large number of nucleic acid samples as indicated by Table 1 Though a variety of signal shapes have been reported we are here concerned only with the (in our experience) dominant and well-defined absorption line characterized at room temperature by a maximum at g = 0 71444 f/H = 2 15–2 25 (f is the frequency of observation in Mc /s , H, the field for maximum absorption in gauss) and a width between points of largest slope of $\Delta H \simeq$ 1,000–1,500 gauss Though both g and ΔH increase appreciably in magnitude as the temperature is decreased the intensity of the resonance remains constant within experimental error from 300° K down to 20° K at least

The ferromagnetic nature of the phenomenon has been confirmed in the case of the three most strongly magnetic samples by demonstration of remanent moments and coercive forces[5] The static magnetic moments of these samples also proved independent of applied field and ambient temperature over wide ranges as expected Quantitative comparisons between the electron-spin resonance intensities and the static moments gave agreement within the experimental errors Such comparisons for two DNA samples are shown in Table 2

The number of unpaired spins responsible for an observed electron-spin resonance signal depends on whether the spins are paramagnetic or ferromagnetic The ratio of these spin concentrations is

$$\frac{N_{\text{para}}}{N_{\text{ferro}}} = \frac{3kT}{g\beta H_0} \, \frac{S'}{S(S+1)}$$

in which k is the Boltzmann constant, T the temperature, g the observed g-factor, β the Bohr magneton, H_0 the magnetic field, S' the electron spin in the ferromagnetic state and S the spin in the paramagnetic state For $S' = 2$ and $S = 1/2$ this ratio is slightly larger than 4,000 for experiments performed at 300° K with 11 7-kMc /s microwaves The intensity of the nucleic acid absorption signal has been compared with that due to a known concentration of paramagnetic ions in a diamagnetic host (1 per cent Ni^{2+} in $KMgF_3$) in order to calculate the number of paramagnetic spins ($S = 1/2$) required to produce an equivalent electron-spin resonance absorption The comparison can, of course, only be made at a particular temperature, 300° K being chosen in the present work A rough indication of these equivalent spin densities is given in Table 1 More exact numbers are shown for the two strongly magnetic samples in Table 2, as are ferromagnetic spin densities ($S' = 2$) calculated on the basis of the formula given above

Identification of iron as the most likely source of the observed ferromagnetism had been established by X-ray fluorescence analysis[5] (see also ref 4) In Table 2 we present the results of a quantitative analysis of the amount of iron in these samples which was not removed by treatment with versene The concentration of iron is much larger than N_{ferro} Lack of numerical agreement between the two sets of numbers is not an argument against inorganic iron compounds as the source of the ferromagnetism since the excess iron can be accounted for in a number of ways, some of which are mentioned later

Table 1. SAMPLES EXAMINED WITH ELECTRON-SPIN RESONANCE TECHNIQUES

The intensity refers to a specific absorption line described in the text. The criteria, strong, medium, weak, and very weak, correspond crudely to more than 10^{20}, 10^{20}–10^{19}, 10^{19}–10^{18}, less than 10^{18} equivalent paramagnetic electron spins ($S = 1/2$)/gm at room temperature

* Present address Department of Theoretical Chemistry, University of Cambridge

Since the existence of the iron in a separate, probably inorganic phase was suspected, several samples were examined by electron microscopy. Dense platelets were found rather randomly embedded in groups of DNA molecules (Fig. 1). (I. Isenberg has also observed such inorganic inclusions in protamine nucleate by electron microscopy—private communication.) The diffraction pattern of the platelets definitely identifies them as single crystals of inorganic compounds (Fig. 2) though no chemical identification was possible from these discrete Laue patterns taken in arbitrary crystal directions. The relative number densities and average sizes of these inclusions (~ 1000 Å maximum linear dimension) correlates quite well with the relative levels of magnetism found. It has not been possible to remove the platelets by simple filtration of water solutions, filtration after ultrasonic agitation or centrifugation. A variety of quite large inorganic crystallites were brought down by centrifugation and filtration, some of these even proving quite strongly magnetic, however, the intensity of the electron-spin resonance signal in the supernatant DNA and the occluded platelet count were not appreciably changed. It appears that the embedded inorganic particles are tightly bound to the surrounding nucleic acid molecules which serve to protect the particles from chemical attack and drag the nucleic acid 'shroud' with them when mechanical separation is attempted.

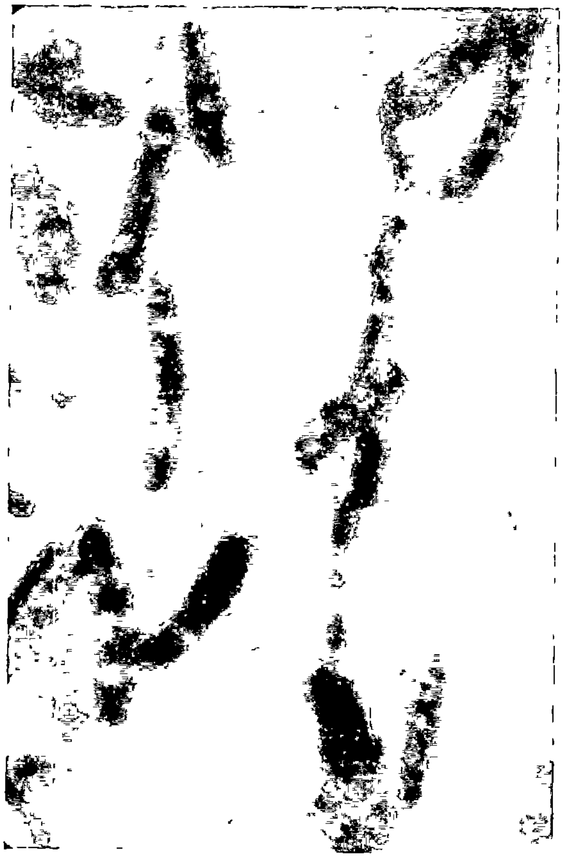

Fig. 1. Electron micrograph (80 keV.) of a nucleic acid sample (calf thymus ΣII) showing crystalline inorganic inclusions in groups of DNA molecules

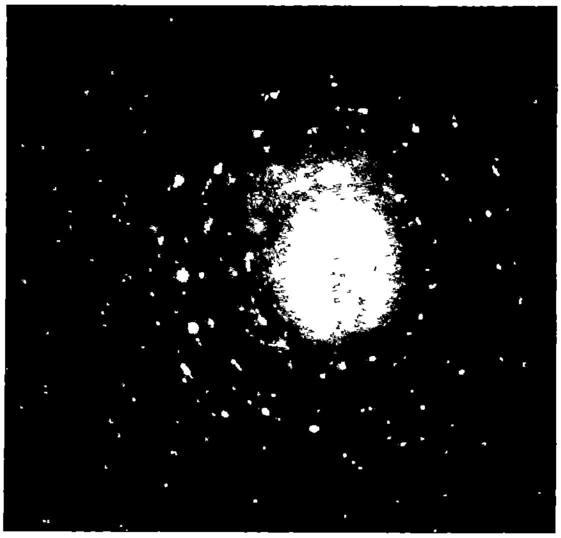

Fig. 2. Selected area electron diffraction pattern (80 keV.) from a group of crystalline inclusions similar to those shown in Fig. 1

Failure to identify the chemical composition of the occluded platelets by electron diffraction and to separate it from its host DNA for chemical analysis led to attempts at magnetic identification. The electron-spin resonance signal of a DNA sample (calf thymus ΣII′) has been observed as the microwave cavity was heated with a nitrogen gas atmosphere present. The spectrum found at 900° K. is quite similar to that seen at 300° K., but the line intensity decreases and the line shape becomes complex at somewhat higher temperatures though it returns to its usual shape and intensity on lowering the temperature. At these high temperatures the DNA is completely charred, once again emphasizing the lack of correlation between the ferromagnetic resonance and the molecular structure of DNA. (A sharp paramagnetic free-radical resonance is observed at $g = 2.00$ after the sample has charred appreciably.) Since the ferromagnetic resonance is still visible at 900° K. we can eliminate Fe_3O_4 as its origin since its Curie temperature is 855° K. While αFe_2O_3 with a Curie temperature of 950° K. appears possible, it must be eliminated since it is a parasitic ferromagnetic material the magnetization of which is too small to account for the observed signal. Also the resonance of αFe_2O_3 disappears suddenly near 260° K. whereas that of our nucleic acid samples does not[7]. This might, however, account for the disappearance of resonance reported by Blumenfeld[1]. (Another alternative in this regard would be Fe_3O_4 since its resonance is reported to broaden quite rapidly below 115° K. (ref. 8).) At present we are unable to suggest a specific iron compound the properties of which exactly parallel the behaviour of our nucleic acid samples. However, we do find a close parallelism in a preparation of colloidal magnetic particles produced by coprecipitation of Fe^{3+} and Fe^{2+} ions from solution[9]. These particles are of nominal composition Fe_3O_4, but evidently differ significantly from macroscopic crystals of that material. It would appear that this oxide-hydroxide of iron is the form responsible for the greater part of the resonances observed in nucleic acid preparations.

The rather low moment per iron atom found in the nucleic acid samples may be due to a number of causes: partial compensation of one magnetic sub-lattice by another (ferrimagnetism), lack of alignment of magnetic moments near the surface of particles due to strong local anistropy, formation of additional weakly magnetic phases, for example, αFe_2O_3, iron hydroxide, isolated ions

The next question is whether or not the iron ions which are commonly found as trace impurities in nucleic acid samples exist in a ferromagnetic form *in vivo*. We examined the resonance spectrum of salmon sperm heads which had been prepared, dialysed extensively and treated with versene by Dr N Simmons When they were first observed no broad electron-spin resonance was observed, in spite of the fact that Simmons's analysis showed a large concentration of iron However, after storage at ~4° C for several months, the electron-spin resonance spectrum was examined again and a weak ferromagnetic resonance was observed In a similar fashion we observed the electron-spin resonance spectrum of a freshly prepared sample of bacteriophage *E. coli T*-2 which was kindly given to us by Prof E. Lennox At first the dried bacteriophage showed several sharp resonance lines, characteristic of paramagnetic impurities However, after several months it too showed a weak ferromagnetic resonance which was not discernible at first.

In our opinion these observations are best explained by the following hypothesis the iron found in nucleoproteins is present in the living cells though not in the concentrated ferromagnetic form The latter, an oxide-hydroxide perhaps approximating Fe_3O_4 in composition, may be precipitated during extraction of nucleic acids or may even form quite slowly in intact but dried organisms The observed clumping of nucleic acid molecules about the inorganic platelets may be evidence for nucleation of the colloidal precipitation at charged sites, for example, the phosphate side groups. That the iron and other trace metals found in nucleic acid samples are indeed present in the biological source is assured by the work of Wacker and Vallee[10]

VARIATIONS IN THE NUCLEAR DEOXYRIBONUCLEIC ACID CONTENT IN THE ADRENAL CORTEX OF THE FEMALE WHITE RAT DURING THE ŒSTRUAL CYCLE

By E. BRAÑEZ and H. ROELS

Department of Human and Comparative Anatomy, University of Ghent

USING the cytophotometric technique for determination of the mean nuclear deoxyribonucleic acid (DNA) content as a test of cellular activity, one of us[1] investigated the function of the different layers of the adrenal cortex Arguments in favour of the opinion of Deane and Greep[2] were provided According to these authors the zona fasciculata is the glucocorticoid-producing layer, which function is dependent on the adrenocorticotrophic hormone secretion of the adenohypophysis, the zona glomerulosa is the mineralo-corticoid-producing layer and independent of the hypophysis The zona fasciculata interna and the zona reticularis are considered to be reserve layers. In the present investigations we have investigated the nuclear DNA content in the adrenal cortex of the female white rat during the different stages of the œstrual cycle It has already been shown by several authors[3-6] that the adrenal weight increases during œstrus. Hunt[7] has observed variations of the mitotic activity in the zona glomerulosa during the œstrual cycle

In a series of female white rats the œstrual cycle was determined by observing vaginal smears during two weeks After this period 5 animals in diœstrus, 4 in proœstrus and 5 in œstrus were selected and killed The adrenals were then fixed, dehydrated, embedded, sectioned and stained by the Feulgen reaction. The DNA content of about 50 individual nuclei in every layer of the cortex was determined by means of the cytophotometric technique of Lison[8]. Table 1 shows a survey of the pooled results

The distribution of the nuclear DNA in the different layers during diœstrus is very similar to that observed in the male cortex. This content is indeed significantly lower in the zona fasciculata interna and reticularis than in the zona fasciculata externa ($P < 0$ 001) In the zona glomerulosa, however, this content is 6 per cent lower than in the fasciculata externa ($P < 0$ 001) In the male rate the DNA content is generally the same in these two layers. In a few instances only, a lower content was observed in the zona glomerulosa[1]. In proœstrus the general distribution is preserved, but in every layer the DNA content is decreased This decrease is not,

Table 1

G , zona glomerulosa, *F E* , zona fasciculata externa, *F I* , zona fasciculata interna, *R* , zona reticularis

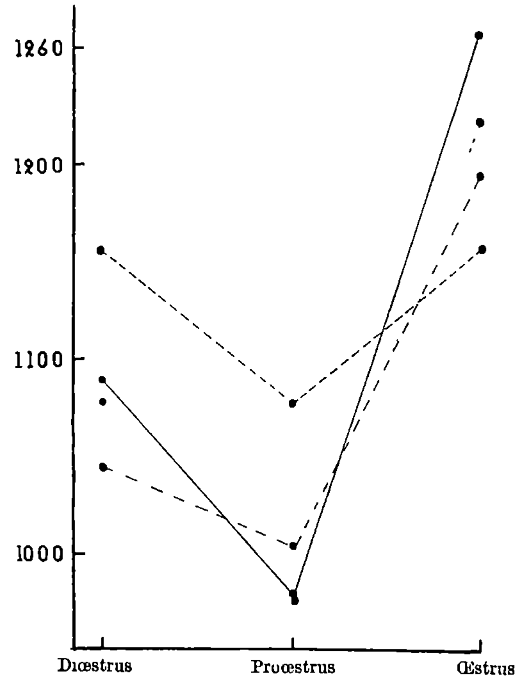

Fig 1 Variations in the nuclear DNA content in the different layers of the adrenal cortex during the œstrual cycle ---, zona fasciculata externa, ——, zona glomerulosa, , zona reticularis, —·—, zona fasciculata interna

however, significant in the zona fasciculata interna In œstrus the nuclear DNA distribution is strikingly changed. The differences between the zona fasciculata externa and the other layers are reversed In comparison with the proœstrus the DNA content in the zona glomerulosa is increased by 29 per cent and exceeds the zona fasciculata by 9 per cent The DNA content of the zona fasciculata externa returns to the value observed during diœstrus The DNA content of the zona fasciculata interna is increased by 19 per cent and by 27 per cent in the zona reticularis Fig 1 summarizes these variations during the œstrual cycle

The decreased DNA content in the four layers during proœstrus suggests a general inhibition of cell activity during this period. We have not found any biochemical and physiological observation in the literature until now which could support this conclusion The most prominent variations are found, however, during œstrus The increased DNA content in the zona fasciculata interna and reticularis suggests a stimulation of the corticosterone secretion. This result fits in with the already observed increase in adrenal weight[3-5] during œstrus and after œstrogen treatment[6] and with the increase in nuclear DNA in the zona reticularis of the male rat after œstrogen administration[1], it is also in agreement with the biochemical analysis of ketosteroid excretion during the œstral cycle[9] The changes of the nuclear DNA content develop within the very short time of one day. Very striking, also, is the increase of 29 per cent observed in the zona glomerulosa during œstrus This would indicate a stimulation of the aldosterone secretion Hunt[7] has already observed an increased mitotic activity in this layer Only a few biochemical data are available at present to explain this observation Gormall, Robertus and Laidlow[10] found a rise of aldosterone excretion after œstrogen treatment in one patient Our results fit in with earlier observations on the influence of stilbœstrol on the cortex of guinea pig and hamster[5]

These observations are once more in contradiction to the general agreement of the constancy of nuclear DNA and show that the variations of the DNA content may develop within a very short time in correlation with cell-activity

EFFECT OF PLANT GROWTH COMPOUNDS ON UPTAKE OF AMINO-ACIDS BY PLANT ROOTS

By D. E WRIGHT*

McGill-Montreal General Hospital Research Institute, 3619 University Street, Montreal

DURING an examination of the uptake of amino-acids by plant roots[1], it was noted that the herbicide 2,4-dichlorophenoxyacetic acid affected the amount of amino-acid taken up Since other workers[2-4] have reported effects by indole-3-acetic acid or 2,4-dichlorophenoxyacetic acid on uptake of solute it was decided to examine this effect further

Seeds sterilized with a dilute hypochlorite solution were germinated and grown in the dark at 25° under sterile conditions in Petri dishes containing filter paper moistened with a dilute salt solution After 5 days the roots were excised, washed, and blotted dry for weighing into 50-ml Erlenmeyer flasks or in Warburg vessels The flasks contained 0·02 *M* sodium phosphate solution, *p*H 5 2, 2 m*M* radioactive amino-acid and any additions as required The flasks were incubated in air for 2 hr at 25°, the roots washed free of medium and extracted with 80 per cent ethanol The radioactivity released from the roots was determined by drying an aliquot on an aluminium planchet and counting under a thin-window gas-flow counter Full details of the methods used are reported elsewhere[1]

The effect on glycine transport into mustard roots by several plant growth substances is shown in Table 1 In this experiment the roots were incubated for 45 min in 5×10^{-5} *M* solutions of the hormones before adding the labelled glycine.

---

* Present address Lincoln College, Christchurch, New Zealand

Table 1 EFFECT OF PLANT GROWTH SUBSTANCES ON UPTAKE OF GLYCINE BY MUSTARD ROOTS

Growth substance	Relative glycine uptake (percentage of control)
Indole-3-acetic acid	84
Indole-3-butyric acid	56
Indole-3-propionic acid	57
Ethylindoleacetate	94
Gibberellic acid	99
Maleic hydrazide	88
Furyl acrylic acid	8
2,4-Dichlorophenoxyacetic acid	39
2,4,5-Trichlorophenoxypropionic acid	16
2,4,5-Trichlorophenoxyacetic acid	29
Naphthalene acetic acid	55
β-Naphthoxyacetic acid	55
Methylnaphthaleneacetate	61
Naphthalene acetamide	104

Roots were incubated in 0 02 *M* sodium phosphate solution, *p*H 5 2 with 2 m*M* glycine-1-^{14}C Growth substances were added to give a final concentration of 5×10^{-5} *M*, 45 min prior to adding the radioactive glycine

The most effective inhibitor was furyl acrylic acid followed by the commonly used herbicides 2,4-dichlorophenoxyacetic acid, 2,4,5-trichlorophenoxyacetic acid and 2,4,5-trichlorophenoxypropionic acid Indolebutyric, indolepropionic, naphthaleneacetic and β-naphthoxyacetic acids, and methylnaphthalene acetate all reduced uptake by 40–50 per cent. Indoleacetic acid, ethyl indoleacetate, gibberellic acid, maleic hydrazide and naphthalene acetamide had little or no effect.

The inhibition by 2,4-dichlorophenoxyacetic acid was not confined to the uptake of glycine by mustard roots Under the same conditions as in Table 1, this herbicide reduced transport of methyl labelled L-methionine into mustard by 50 per cent and glycine transport into wheat roots by 40 per cent

Different concentrations of 2,4-dichlorophenoxyacetic acid were tested for inhibitory action (Table 2) At concentrations of 10^{-5} *M* and less, there was either no effect or a slight stimulation of glycine transport and respiration At 10^{-4} *M*, oxygen consumption was unaltered while glycine uptake was reduced by 26 per cent At 2×10^{-4} *M*, oxygen uptake was lowered by 18 per cent and glycine transport by 52 per cent At higher concentrations, both glycine and oxygen uptake were markedly reduced

Table 2. EFFECT OF DIFFERENT LEVELS OF 2,4-DICHLOROPHENOXYACETIC ACID AND 2,4-DINITROPHENOL ON UPTAKE OF GLYCINE BY MUSTARD ROOTS

Addition to medium	Concentration of addition (*M*)	Relative uptake (percentage of control)	
		Glycine	Oxygen
	—	100	100
2,4-Dichlorophenoxyacetic acid	10^{-3}	18	18
	5×10^{-4}	27	38
	2×10^{-4}	48	82
	10^{-4}	74	100
	5×10^{-5}	109	109

2,4-Dinitrophenol	10^{-4}	10	20
	10^{-5}	43	124
	10^{-6}	97	94

Roots were incubated in Warburg flasks in 0 02 *M* sodium phosphate *p*H 5 2, 2 m*M* glycine-1-^{14}C and 2,4-dichlorophenoxyacetic acid or 2,4-dinitrophenol at the concentrations given above The flasks were shaken for 2 hr at 25°, the gas phase being air

These results can be compared with those found using 2,4-dinitrophenol, where glycine transport was lowered despite a stimulation in respiration This suggests the possibility that the actions of 2,4-dichlorophenoxyacetic acid and 2,4-dinitrophenol are similar and perhaps due to effects on oxidative phosphorylation

Preliminary experiments with the incorporation of phosphate-32 into root nucleotides provide supporting evidence for an effect on oxidative phosphorylation by 2,4-dichlorophenoxyacetic acid as reported by Switzer[5] and Khubutiya[6]

It is reasonable to conclude that the reduction of amino-acid transport into plant roots caused by 2,4-dichlorophenoxyacetic acid is probably due to reduced levels of adenosine triphosphate, since uptake of amino-acid is known to be an energy-requiring process[1]

This work was supported by a grant from the National Science Foundation I wish to thank Prof J. H Quastel for suggesting the topic and for his guidance.

TESTS FOR LIVER DYSFUNCTION IN DOGS

By CELIA M. HOE

Division of Chemical Pathology, Department of Pathology, Royal Veterinary College, London

THE reason for undertaking this investigation was to try to select a few simple biochemical techniques which would enable the veterinary surgeon to gain useful information about the state of the patient's liver without having to resort to laparotomy or biopsy

The pattern of the work had to be governed by the material available, which was provided, for the main part, by the Beaumont Animals Hospital It was not considered practical to undertake any test which necessitated even the temporary hospitalization of the patient, or the preliminary intravenous injection of any substance (for example, sulphobromphthalein) Therefore, tests had to be developed which could be carried out on a single blood sample

Serum Alkaline Phosphatase Estimations of serum alkaline phosphatase were carried out on 463 samples, and the normal value was found to be 8 King Armstrong (K.A) units In dogs, a species in which extrahepatic obstructive jaundice would appear to be a less common clinical entity than in humans, very high values were given by hepatocellular jaundice, for example, a value of 120 K A units was found in a case of leptospiral jaundice, and it is an interesting speculation that the pathology of the hepatic cell of the dog may differ from that of man, possibly showing a greater tendency to undergo cloudy swelling and thus to produce intrahepatic obstruction.

Raised serum alkaline phosphatase values were also found in young animals undergoing active growth of bone tissue, and in conditions in which there was an interference with calcium and phosphorus metabolism, that is, bone lesions (9–90 K A. units), and some cases of nephritis (9–60 K.A. units), cystic calculi (10–40 K.A. units) and enteritis (9–100 K.A. units). My experience of this test showed that 95 per cent of dogs with definite liver involvement gave positive results, and so did 75 per cent of dogs with suspected liver involvement. It also indicated the main disadvantage of the test, which is that high values are given by conditions which do not involve the liver (*vide supra*).

Serum Transaminases. Serum glutamic pyruvic transaminase and serum glutamic oxaloacetic transaminase.

Normal values were calculated from estimations carried out on the sera of 11 young healthy dogs, and were taken as follows: serum glutamic pyruvic transaminase less than 20 Sigma Frankel units, serum glutamic oxaloacetic transaminase less than 30 Sigma Frankel units. These values were comparable with those of Cornelius, Bishop, Switzer and Rhode[1], and Malherbe[2]. The results of estimations on more than 70 different clinical cases indicated that increases of transaminase activity, especially serum glutamic pyruvic transaminase (Hoe[3]), are reliable indications of early liver cell damage, before it is indicated by other tests. For example, in four puppies which had been inoculated with the virus of hepatitis contagiosa canis, considerable increases in serum glutamic pyruvic transaminase could be seen 5 days after inoculation while other liver function tests remained normal. Serum glutamic oxaloacetic transminase was also raised, but not generally as significantly.

Total Serum Cholesterol. Total serum cholesterol values were calculated for two groups of normal dogs, household and kennel. Normal values were found to be: household dogs, 258·0 ± 36·3 mgm/100 ml.; kennel dogs, 186 ± 13·9 mgm/100 ml. It was thought that these different values were probably caused by dietary differences, the average domestic pet living in the house receiving a diet considerably higher in cholesterol than that fed to most kennel dogs. In view of these findings, cholesterol values greater than 299 mgm/100 ml. were taken as raised.

The estimation of total serum cholesterol was carried out on 250 sera. Although raised values were found in only 57 per cent of jaundice cases, this estimation would appear to be of considerable use in the diagnosis of other diseases, including nephritis, most cases of which gave values in the 300–499 mgm/100 ml range. Raised values were also encountered in all cases of diabetes mellitus (310–1,360 mgm/100 ml.), and also in two animals which afterwards developed the disease, but which were not showing glucosuria at the time the serum was first examined; presumably this indicates a general disturbance in fat and carbohydrate metabolism found in the pre-diabetic patient. Two cases of hypothyroidism were encountered, and one of these was particularly interesting. When presented at the clinic, this Alsatian puppy was 9 months old, measured 25 cm high and weighed 3·6 kgm. A diagnosis of hypothyroidism was made when the total serum cholesterol value was found to be 700 mgm/100 ml. This value decreased to the normal level when thyroid therapy was instituted.

Serum Uric Acid. About 70 per cent of the 240 cases examined during this survey gave uric acid values less than 0·5 mgm/100 ml., and only 11 per cent were higher than 1 mgm/100 ml. If one compares the relative merits of serum alkaline phosphatase and uric acid estimations as tests of liver function it can be seen that uric acid is not such a good index as serum alkaline phosphatase. While 95 per cent of the cases with the highest serum alkaline phosphatase levels showed some liver involvement, the corresponding figure for uric acid was only 75 per cent; also, while all cases of jaundice gave raised serum alkaline phosphatase values 86 per cent showed increased serum uric acid. 46 per cent of the cases of nephritis examined lay within the range 0·5–0·99 mgm/100 ml. It was noticed during this work that high uric acid figures frequently appeared to carry a poor prognosis for the patient, and hence were found in most moribund animals.

Serum Bilirubin. This estimation was carried out on some 300 sera, but much difficulty was experienced in evolving a technique which was sufficiently sensitive to measure the very low concentrations of bilirubin found in the sera of non-jaundiced dogs. The most suitable method seemed to be that of Powell[4]. No attempt was made during this investigation to differentiate between direct and indirect bilirubin. Accurate measurement of the small quantities involved presented so much difficulty that it was not deemed worth while attempting the more complicated techniques which would have been necessary, especially as hæmolytic jaundice does not seem to be of much practical importance in dogs in the United Kingdom.

It was also noted that dogs showing bilirubinuria did not in many instances show bilirubinæmia. It has been stated[5] that about 20 per cent of apparently normal dogs excrete bilirubin in their urine. This finding has been confirmed by Wilkinson (personal communication, 1960).

Serum Proteins. Relative percentages of serum proteins for normal dogs were calculated after electrophoresis had been carried out on the sera of 26 young healthy dogs living under similar conditions. The method of Jencks, Jetton, and Durrum[6] was used and results were as follows: albumin, 57·2 ± 0·95, α_1-globulin, 6·2 ± 0·37, α_2-globulin, 9·7 ± 0·46; β_1-globulin, 8·8 ± 0·54, β_2-globulin, 9·0 ± 0·37, γ-globulin, 10·4 ± 0·55, albumin globulin ratio, 0·76 ± 0·087. Electrophoresis was also carried out on the sera of 140 dogs suffering from various diseases. Albumin decreased in most of the diseases investigated and this change was reflected in the albumin globulin ratio. Changes in α_2-globulin appeared to be non-specific. β_1-Globulin showed a significant increase in most of the neoplasia cases, but was decreased in all cases of jaundice and the majority of diabetes mellitus cases. β_2-globulin was a variable factor in most of the conditions studied but was always raised in jaundice. γ-Globulin was raised in jaundice and cirrhosis, but decreased in more than 90 per cent of the cases of diabetes mellitus, and it was felt that this was of some significance in view of the fact that such poor resistance to infection is shown by most human diabetic patients. Cirrhosis gave a characteristic electrophoresis diagram with poor resolution in the β- and γ-bands.

During this part of the investigation an attempt was made to establish a relationship between the results of the Kunkel turbidity test and the relative percentage of the γ-globulin as determined by electrophoresis. There was a significant correlation between the two factors, but the scatter about the regression line was too great to permit an accurate evaluation of γ-globulin by this method. It seems, however, that the Kunkel test can be used semi-quantitatively and this is in general agreement with the findings of most workers in human medicine.

The Takata Ara test appeared to be less specific than the Kunkel, and gave positive turbidities and flocculations for increases in any of the globulin fractions From my work on these tests it appears that in the absence of a positive Kunkel, a positive reaction with the Takata Ara may indicate an increase in the globulin fractions other than the γ-globulin

The most useful tests investigated seem to be serum alkaline phosphatase, the transaminases and electrophoresis, all of which can be performed on a a total of 0 9 ml. of serum. When it is possible these tests should be supplemented by the estimation of serum cholesterol, which can give useful information in cases of nephritis, pre-diabetes and in hypothyroidism

The estimation of serum alkaline phosphatase has been shown to be a useful index of liver function, and when used with discrimination it will yield more reliable information than that given by serum bilirubin estimations, except in the case of hæmolytic jaundice The transaminase tests (especially serum glutamic pyruvic transaminase) play an important part in the diagnosis of active liver cell damage and necrosis before any abnormality is shown by any other liver function test. Electrophoresis is of considerable value, especially in the diagnosis of cirrhosis.

Practical details of this work are published elsewhere (Hoe and Harvey[7,8])

I wish to thank Dr D G Harvey for advice and help throughout this work, also Mr G C Knight and my other colleagues in the Departments of Medicine and Surgery for the provision of clinical material I would like to express the sincere gratitude I feel to the late Mr. A. B MacIntyre, whose kindness and inspiration did much to further the work I am indebted to the Trustees of the Clement Stephenson Fund for a scholarship

CHANGES OF BLOOD VOLUME IN THE PRE-HIBERNATING AND DEEP-HIBERNATING HEDGEHOG

By Dr. EINAR ELIASSEN
Zoological Laboratory, University of Bergen

IN hibernating animals the blood volume is decreased during the hibernation sleep Although everyone who has been working on the physiology of hibernation is familiar with this decrease in blood volume, by simple observations, only scanty data on the blood volume of these animals appear in the literature[1,2]

In this Laboratory we have measured the blood volume of the common European hedgehog, *Erinaceus europaeus*, L at normal body temperature (about 35° C) as well as at low temperatures (about 5° C) The measurements were made by way of the ordinary dilution method using Evans blue The injections were mostly given into the inferior vena cava, and the samples mostly taken from this vessel.

By this method we found a marked decrease in blood volume in the hibernating hedgehog In the 'summer animals' we found the blood volume to be about 8 per cent of the animals' weight, while in the sleeping 'winter animals' the blood volume was found to be about 2 –3 per cent of weight (Fig 1)

The question is raised as to how this decrease takes place To find the answer to this question several analyses are made on the normal blood constituents of the animals, in different stages of hibernation and in the awakened state Further, the weight of the spleen is measured in the same periods when looking for any connexion between blood volume and the well-known function of the spleen to accumulate erythrocytes Finally, the most common constituents of the urine are measured in order to see if dehydration plays any part in the regulation of blood volume

In this discussion it is important to know what we mean by the term 'different stages of hibernation' As the term is being used by me it signifies three different periods of hibernation the pre-hibernating period, the deep-hibernating period, and the period of arousal

In the pre-hibernating period the body temperature is altering from the normal level (about 35° C) to hypothermal levels (about 5° C.) and vice versa, in about 24 hr Such variations in body temperature may take place about five to ten times during the period. The length of this period is about two months, in our animal room taking place in October–November The same tendency of variation in body temperature in hibernating hedgehogs has been reported previously[3]

In the deep-hiberating period (from about December to about March) the body temperature is rather constant, at about that of the room. In the period of arousal the same variations in body temperature as those taking place in the pre-hibernating period, are never observed in this Laboratory The end of

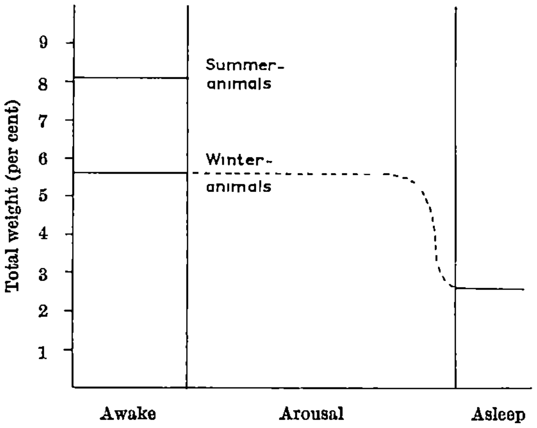

Fig 1 Blood volume—measured as 'Evans blue volume'—of hedgehogs awake, during induced arousal, and in deep hibernation

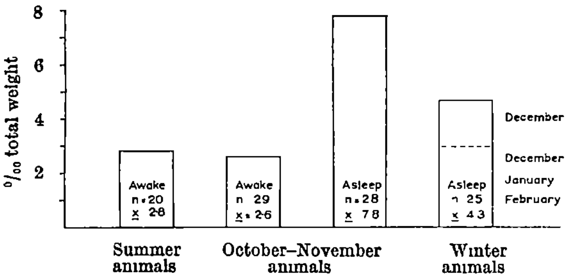

Fig 2 The weight of the spleens in pro mille of body-weight, from hedgehogs in the summer, autumn and winter months

n No of animals, *x*, mean value of weights The diagram representing the spleen weights of the winter animals is divided into two parts by a stippled line. The lower part gives the situation of the spleen weights from animals in deep hibernation, while the upper part gives the corresponding data from animals entering the deep hibernating period

this period is about April, and from that time onwards the animals are named 'summer animals'.

I have measured a great number of spleens from different animals throughout the greater part of a year (Fig. 2) Contrary to my expectations I found the weight of the spleen to be by far the greatest in the animals asleep in the pre-hibernating period, while the weight of the spleen in deep-hibernating animals was nearly the same as that found in the 'summer animals' I take this increase in weight of the spleen as indicating an accumulation of red cells in this organ, and this accumulation as being at its maximum in the sleeping, pre-hibernating animals

Effects of this accumulation of red cells in the spleen on the hæmatocrit and red cell number were measured, and here again the results were rather conspicuous, as both hæmatocrit and red cell number were decreased for 'October–November animals' as compared with the 'winter animals', being almost the same as those for 'summer animals' This change in red cell status during the pre-hibernating period is the same whether the animals are awake or asleep. It seems as if the course of events is not exactly the same in this period, comparing the status of red cells in the blood and the accumulation of red cells in the spleen, since in the latter case there is a great difference in the weight of the spleen when the animals are awake and asleep (Fig 2)

This apparent discrepancy provides the key to further considerations. The possibility exists that a destruction of red cells takes place in the pre-hibernating period, and that the spleen acts as an intermittent reservoir in this period, taking over parts of red cells from the circulation for further transport to the macrophage cells in the liver This would explain why the weight of the spleen is greatest in the pre-hibernating period and afterwards decreases Further, it would explain the decrease in the hæmatocrit and the red cell number in both the awake and sleeping 'October–November animals'. Finally, the decreased blood volume observed in awake 'winter animals' would be explained by the destruction of red cells

Now, the possibility exists that the decrease in hæmatocrit, red cell number, and blood volume could be explained in other ways than by simple destruction of red cells, for example, by accumulation of red cells in some parts of the circulatory system exclusive of the spleen

The following experimental observations provide an answer to these considerations A series of blood-volume measurements—combined with parallel hæmatocrit determinations—has been made on animals during induced arousal from the deep-hibernating state. The animals were aroused by taking them from their room (at about 5° C.) to the laboratory (at about 20° C.). Within 12–24 hr the animals were awake at about 35° C. body temperature, and blood-volume determinations were made according to the Evans blue method mentioned here. The results are given in Fig 1, where the fully-drawn lines give the blood volumes of sleeping and awake animals, and the stippled line the blood volume during different stages of arousal. In Fig 1 attention is directed to the following: (1) The blood volume of awake 'winter animals' does not reach the same level as that of the 'summer animals'. About one-third of the blood is lost (2) There is a rapid increase in the blood volume in the early stages of arousal, reaching its final level at the very beginning of this phase

From (1) the conclusion may be drawn that the decrease in blood volume in the awake 'winter animals' is due to simple destruction of red cells The suggestion that red cells might accumulate somewhere in the circulatory system of the awake animals does not seem to be very likely in the case referred to, where heart-rate and blood pressure are of the same order in the awake 'winter animals' as in the 'summer animals'[4]. The destruction theory is the more probable as we have observed a pronounced increase in the bile pigment in serum, urine and fæces in the animals in the pre-hibernating period (and to some extent also in the animals in the beginning of the deep-hibernating period). Further, in some of the 'October–November animals' we found the lowest hæmatocrit values ever observed during the course of the present experiments, and these values reveal a decrease in red cells (other things being equal) of about 30 per cent

However, the observed loss of blood by destruction of red cells does not tell the whole story about the decrease of blood volume observed in the sleeping 'winter animals' (Fig 1).

Most likely, the data obtained are a consequence of the method used At low heart-rates the blood flow is extremely slow and the injection of Evans blue in the circulatory blood, and more particularly the distribution of the dye in the plasma, takes a great deal of time Now, there is a limit to this distribution, due to the loss of Evans blue from the blood by diffusion In the experiments referred to in this article the limit was about 3 min in the deep-hibernating animals It seems rather likely that a full distribution does not take place all over the circulatory system during this time (and under this condition), and we should therefore like to name the volume calculated from the experiments on deep-hibernating animals 'the Evans blue volume', rather than the exact blood volume When increase in heart-rate during arousal and as a consequence a more rapid blood flow is obtained, the distribution of the dye should be more quantitative and 'the Evans blue volume' calculated should increase to the value of the true blood volume (Fig 1, 'arousal').

Now, red cells represent only half the blood What about the rest of the blood lost, or more particularly, the plasma ? Here again the results obtained by hæmatocrit determinations are of importance In the pre-hibernating period, we were much surprised to find a rather great scattering of the values, with variations from 36 as a minimum to 56 as a maximum However, as more results were obtained both from animals in this period and the following deep-hibernating period, the scattering in the hæmatocrit (as well as in the red cell number)

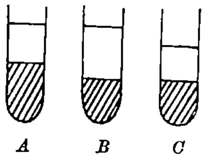

Fig 3 The relation between plasma and red cells *A*, in 'summer animals', *B*, in 'October–November animals', *C*, in 'winter animals'

became more easily explicable. The following hypothesis is based on these results as well as those on blood serum and urine obtained by experiments going on in this Laboratory at the time, but not referred to here

With regard to the blood status during the prehibernating period, two processes are going on with some lag in time. The first one is the destruction of red cells already discussed, and thereupon follows an excretion of plasma substances (water, salts, etc) In the very beginning of the period only destruction of red cells is going on, and the hæmatocrit decreases (Fig. 3). This should explain the lowest values obtained and referred to here. Afterwards the excretion of plasma begins, and the hæmatocrit increases until the normal values are reached, as in the deep-hibernating animals The net result is a decrease in total blood volume

My answer to the question raised at the beginning of this article should be then that the blood volume is decreased mainly by way of red cell destruction and ensuing plasma excretion The spleen is functioning as an intermittent reservoir regarding the accumulation—and perhaps also the destruction—of red cells 'The Evans blue volume' reported in this article is about one-third of the total blood volume in 'summer animals', but must be considered as a false datum More likely this volume reveals pronounced differences in blood-flow in different vascular areas

At this stage further questions arise, and more detailed determinations are called for, the most prominent ones being (1) the part played by the kidney in the regulation of blood volume observed, (2) the determination of the life-time of red cells both in 'summer animals' and 'winter animals'; (3) the proportion of new and old red cells in the same animals, (4) investigation on complement components during the whole cycle of hibernation, to look for any connexion between these components and the destruction of red cells observed

ROLE OF WATER-REGULATING MECHANISMS IN AMPHIBIAN MORPHOGENESIS: A QUANTITATIVE HYPOTHESIS

By PETER TUFT

Department of Zoology, West Mains Road, Edinburgh 9

WATER is the only constituent of the amphibian embryo taken up in appreciable quantities from the environment during the course of development, and it accounts for almost three-quarters of the volume of the fully formed embryo Growth of the embryo and changes in its shape would therefore be expected to involve the uptake or redistribution of water. In the development of *Xenopus laevis*, for example, variations in water content account for almost all the changes in volume that occur, and moreover the water taken up is not uniformly distributed throughout the embryo It is taken up first into the blastocœl, then into the archenteron and, finally, after the latter has collapsed, into the cells themselves[1] This can be demonstrated by measurements of the density of the embryo and of its weight in water (reduced weight) The latter remains almost constant until the early tail bud stage, hence all but a small proportion of the volume changes which occur must be the result of water uptake. (Any change in density of the other embryonic constituents would produce a corresponding change in the reduced weight) A similar conclusion was reached by Rappaport in his work on the growth of explanted amphibian tail buds[2]

Fig 1 shows the volume of intact *Xenopus* embryos of different ages calculated from the density measured in a density gradient, and the reduced weight, measured on a Cartesian diver balance. It will be noticed that the rate of water uptake increases with age until the eighteenth hour, when there is a sudden decrease in volume resulting from the spontaneous emptying of the archenteron cavity. A similar plot of cell volume (calculated from the reduced weight and the density of opened embryos minus the contents of their intercellular cavities) illustrates the change in distribution of water between the cells and the intercellular cavities (Fig 1, open circles)

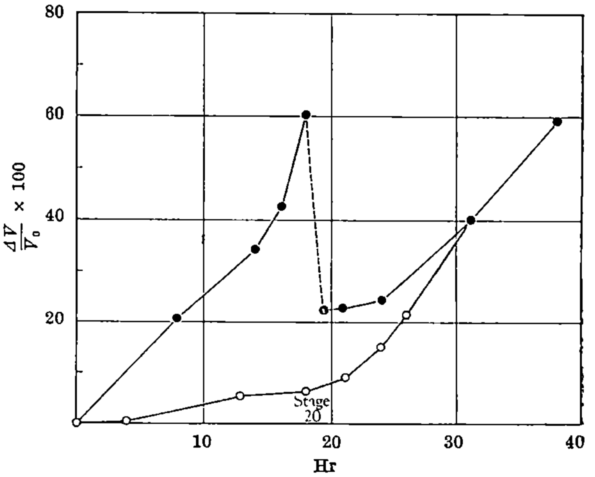

Fig 1 Changes in volume $\frac{(V_t - V_0)}{V_0}$ of *Xenopus laevis* embryos (open circles) and their cells (closed circles) during development at 25° C based on reduced weight and density measurements

$$\text{Volume intact} = \frac{\text{reduced weight}}{\rho_{\substack{\text{intact}\\ \text{embryo}}} - \rho_{\text{water}}} \quad \text{Volume cells} = \frac{\text{reduced weight}}{\rho_{\substack{\text{open}\\ \text{embryo}}} - \rho_{\text{water}}}$$

Each point represents the mean of 5 embryos

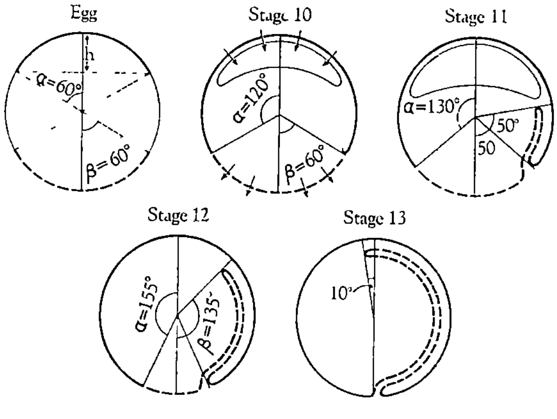

Fig. 2. Diagrammatic summary of morphological data from the *Normal Tables of Xenopus laevis*. Solid line represents the surface of the presumptive ectoderm and neural plate, and the broken line represents the surface of the presumptive endoderm

Measurement of the freezing-point depression of samples taken from the blastocœl and archenteron of single embryos has shown that the osmotic gradient between the environment and the intercellular cavities decreases with the age of the embryo, and therefore cannot by itself account for the observed water movements[2]. An alternative explanation has been suggested based on the notion that the water-regulating mechanisms of the cells give rise to a net influx of water through the roof of the blastocœl and a net efflux through the cells of the vegetative pole of the embryo[3]. If this notion were correct a difference in the magnitude of the two fluxes would account for the accumulation in the blastocœl; the invagination of the endodermal surface would itself account for the filling of the archenteron, and the increase in area of inwardly polarized ectoderm would account for the observed increase in the rate of water uptake.

This idea has been helpful in interpreting the morphogenetic effects of β-mercaptoethanol on the *Xenopus* embryo[4,5], and the chick blastoderm[6]. I have therefore attempted to present it as a quantitative hypothesis that can be tested experimentally.

If it is assumed that the accumulation of water in the embryo is due to the combined effect of two oppositely polarized areas of the embryonic surface, then the rate of water uptake by the embryo will be a function of the area of the inwardly polarized animal pole surface (A_a) and the area of the outwardly polarized vegetative pole surface (A_v). During the early stages of development, before the blastopore is completely closed, the rate of water uptake by the embryo may be written:

$$f'A_a - f''A_v \qquad (1)$$

where f' and f'' are appropriate rate coefficients. After the closing of the blastopore the rate is equal to $f'A_a$.

The areas A_a and A_v change absolutely and relatively to each other during the course of development (Fig. 2), and their sizes may be estimated from independent morphological data contained in the *Normal Tables of Xenopus laevis*[7] which give values for the radius of the embryo, and the angle subtended by a line joining the boundary of the relevant areas to the centre of the embryo and the animal vegetal axis. It is therefore convenient to express A_a and A_v in terms of these angles:

The surface of a spherical segment $= 2\pi rh$

For animal pole surface.

$$h = r(1 - \cos\alpha)$$

$$\text{and } A_a = 2\pi r^2 (1 - \cos\alpha)$$

Similarly $A_v = 2\pi r^2 (1 - \cos\beta)$

where α and β are the angles subtended by the boundary of the animal pole surface and the vegetative pole surface respectively.

Equation 1 then becomes:

Rate of water uptake =

$$2\pi r^2[f'(1 - \cos\alpha) - f''(1 - \cos\beta)] \qquad (2)$$

For the purpose of this argument only two parts of the egg surface need to be considered, first, the area from which the ectodermal surface of the neurula is derived—the pigmented area at the animal pole; and secondly, the corresponding area of the vegetative pole surface from which the lining of the archenteron is derived. The area around the equator is excluded from the argument, because it is the zone of transition between areas of opposite polarity and because there is no means of determining its rate coefficients. It is worth noting, however, that the presumptive mesoderm which forms intercellular cavities much later in development is derived from a region just below the equator.

The morphological data from the standard tables are summarized in Fig. 2. If the values of cos α are plotted against time, a straight line is obtained which shows that the area of the animal pole surface increases at a constant rate from cleavage onwards. A similar plot of values for cos β shows, on the other hand, that area of the vegetative pole surface does not change until stage 10, after which it too increases at a constant rate until stage 13, when it extends as a double hemisphere half-way round the embryo and forms the lining of the archenteron. As both these variables change in a linear fashion, intermediate values of cos α and cos β may be obtained by interpolation.

Although the value of the rate coefficients f' and f'' cannot be determined individually from the present data, it is known that, just prior to the collapse of the archenteron, the surface of the ectoderm and surface of the endoderm have approximately the same area, and since the volume of the cells is almost constant at this stage, all the water entering through the ectoderm must be passing through the endoderm. Therefore at this stage $f' = f''$.

If it is now assumed, as a first step, that f' and f'' are constant throughout development then f' and f'' = constant K and equation 2 becomes

$$\text{Rate of water uptake} = K2\pi r^2(\cos\beta - \cos\alpha) \qquad (3)$$

The value of K may be estimated by dividing the experimentally determined rate of volume change at any stage by the appropriate value of $2\pi r^2 (\cos\beta - \cos\alpha)$:

$$K \frac{\text{Slope of volume change curve}}{2\pi r^2(\cos\beta - \cos\alpha)} \qquad (4)$$

Alternatively it may be estimated from the surface area and the experimentally determined rate of volume change at a stage when the blastopore is closed and all the water entering the embryo accumulates in the archenteron, for example, at stage 20. The values obtained by the two methods are given in Table 1. The experimental values for the rate of water uptake of embryos developing at 25° C. were obtained by combining the results of a number of experiments similar to that illustrated in Fig. 1 and measuring the slope of the curve (Fig. 3) drawn by eye through the mean values of V_t/V_0.

The experimental values so obtained and the corresponding theoretical values calculated from equation (3) are shown in Fig 4. (The theoretical value for 18 hr. was derived from the surface area of the embryo calculated from the linear dimensions given in the *Normal Tables*, assuming that the embryo at this stage is a prolate spheroid) The absence of theoretical values for stages 13 and 20 stems from the fact that it is not known exactly when the blastopore becomes watertight. For comparison the corresponding theoretical and experimental values for the rate of water uptake by embryos developing at 20° C are also shown in Fig. 4

It will be seen that the experimental values, particularly for embryos developing at 25° C , are close to the theoretical values at all stages. Thus the assumptions on which this analysis is based appear to be consistent with the experimental observations. The hypothesis in its present form, therefore, seems to provide an adequate qualitative and quantitative description of some of the morphogenetic changes that occur during the early development of *Xenopus laevis* There seems to be no reason why it should not also be helpful in explaining the growth and maintenance of the fluid content of other intercellular cavities, for example, the neural tube, eye cup, cœlom and amniotic cavity, and perhaps in describing the changes in shape of cells and embryonic organs.

I am grateful to Prof Michael Swann in whose Department this work was carried out, and to my colleagues for their help, in particular Dr P. D. Mitchell, Dr H Kacser and Dr P. C Croghan. I am also very grateful to the Nuffield Foundation, which made the project possible

GROWTH HORMONE CONTENT OF SERUM IN INFANTS, CHILDREN, ADULTS AND HYPOPITUITARY DWARFS

By Dr. J GIRARD, Dr. M. VEST and Dr N ROTH
Children's Hospital, University of Basle, Switzerland

THE preparation of purified human growth hormone (HGH) from human pituitaries (Raben, Li) has made it possible to develop an immunological assay of human growth hormone by means of a human growth hormone rabbit antiserum

The hæmagglutination-inhibition method is sensitive enough to detect human growth hormone down to 0 2 μgm /100 ml [1]. The validity of the results depends chiefly on the specificity of the human growth hormone antiserum and the purity of the hormone preparation That human growth hormone has antigenetical properties has been repeatedly shown by antibody formation in the rabbit[1-10], and by anaphylactic reactions in the guinea pig[4]

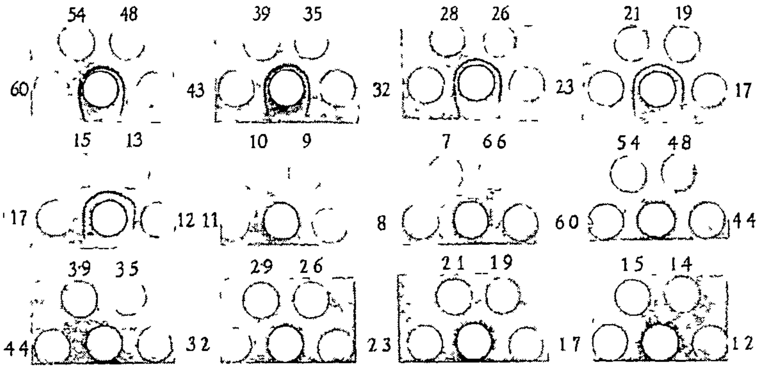

Fig. 1. Precipitin reaction between undiluted human growth hormone/rabbit antiserum (titre 1 : 800) and hormone dilutions (human growth hormone–Raben), as determined by the Ouchterlony technique. Dilutions of growth hormone, in μgm./ml., are arranged clockwise around the central well, which contains the antiserum

When human growth hormone and its specific rabbit antiserum are tested by the gel-diffusion method of Preer[3], the precipitin ring test[7,9], the Ouchterlony technique[7], immunoelectrophoresis[8,9] and by the hæmagglutination-inhibition test[1-3,10], they appear to be homogeneous.

Human growth hormone can be localized in sections of human anterior pituitaries and eosinophilic adenomas in the eosinophilic cells by means of fluorescent rabbit antibodies[6]. This can be regarded as further proof of specificity. Small amounts of contaminating antibodies cannot be entirely excluded by the methods mentioned, however, because the antiserum is diluted for use in the hæmagglutination–inhibition method these possible contaminants can be disregarded. Thyroid stimulating hormone, adrenocorticotrophic hormone and insulin do not interfere with the hæmagglutination-inhibition test of human growth hormone. Tests with the serum of hypophysectomized patients did not show inhibition in the hæmagglutination technique, indicating that only proteins of pituitary origin produce the specific inhibition[3].

Latex agglutination detects growth hormone in amounts down to 0·01 μgm. (ref. 5) and precipitin-ring-test down to 0·1 μgm./0·5 ml. sodium chloride[4]. So far only the hæmagglutination method has been applied to the estimation of concentration of growth hormone in human serum.

The method used for the hæmagglutination inhibition reaction was essentially the one described by Read[1]. Human growth hormone rabbit antiserum was produced by immunization with Raben's hormone preparation[11]. Titres ranged around 1 : 1,000. Sheep erythrocytes were washed in physiological saline, treated with diluted tannic acid and incubated with human growth hormone. With the cells so prepared, the titre of the human growth hormone rabbit antiserum was measured. For use the antiserum is diluted with physiological saline containing guinea pig serum (80 parts : 1 part, v/v). Dilutions of standard hormone solution were added to a constant amount of the diluted antiserum. Simultaneously serial dilutions of the serum to be tested were incubated with the same amounts of the antiserum. If all the antibodies are neutralized by the growth hormone of the serum or the standard solution, hæmagglutination is prevented. With decreasing hormone content of the dilutions, increasing hæmagglutination is observed. The end-point is that concentration of growth hormone at which complete hæmagglutination first occurs. Controls using washed and tanned erythrocytes without human growth hormone coating and hormone-coated cells without antiserum were always negative. The sensitivity of the method can be regulated by varying the antiserum dilution. If the dilution is not carried too far, that is, not quite to the titre-dilution, the end-point of the hæmagglutination-inhibition can be determined exactly. All samples were tested in quadruplicate and gave identical results, even in different assays.

Our own work using the Ouchterlony agar diffusion technique showed one single precipitation line between the undiluted human growth hormone rabbit antiserum and hormone concentrations ranging from 6,000 μgm./100 ml. down to 300 μgm./100 ml. (Fig. 1). No precipitation was seen when human growth hormone was tested against anti-human serum. In contrast a specific antiserum against human albumin with a high titre in one test produced a precipitation line, but only if growth hormone was used in a concentration of 100 mgm./100 ml., an amount far greater than that used in the hæmagglutination technique. On subsequent trials this observation could not be reproduced. This finding could be interpreted as indicating contamination of the growth hormone preparation with small amounts of albumin.

The growth hormone concentration in the serum of normal children and adults in our series using the hæmagglutination-inhibition technique varied between 24 μgm./100 ml. and 60 μgm./100 ml. for children and between 16 μgm./100 ml. and 36 μgm./100 ml. for adults (that is, 240 mμgm./ml.–600 mμgm./ml. and 160 mμgm./ml. and 360 mμgm./ml.). The mean values for children (42 children without cord-blood values: 39·6 μgm./100 ml., standard deviation 10·48) are significantly greater than the mean concentration in adults (18 adults: 26·0 μgm./100 ml., $S.E. = 5·53$), $P = 0·001$. The mean value of growth hormone in puberty (14 children from 11 to 17 years) is 43·43 μgm./100 ml. ($S.E. = 8·61$). This value does not differ significantly from the mean growth hormone concentration of 28 children under 11 years of age (without cord-blood values), which amounts to 37·75 μgm./100 ml. ($S.E. = 10·94$) with $P = 0·1–0·05$.

In nine specimens of cord-blood the values ranged from 24 to 36 μgm./100 ml. (that is, 240–360 mμgm./ml.).

Fig. 2 shows the results in relation to the age of the individuals tested. There was no clear relation between the growth hormone concentration at a certain age and the rate of gain in height of the corresponding period. There is a slight increase in the mean growth hormone concentration between the age of 11 and 17 years (puberty), which is not significant. In contrast, values of growth hormone in 18 adults showed an average which is significantly lower than the average during childhood.

In three hypopituitary dwarfs we found concentrations of growth hormone which are well below the lowest values encountered in normal children and adults. In this group a 6-year-old boy and a 13·5-year-old girl had a concentration of 6 μgm./100 ml., a 14·5-year-old male dwarf, who previously had

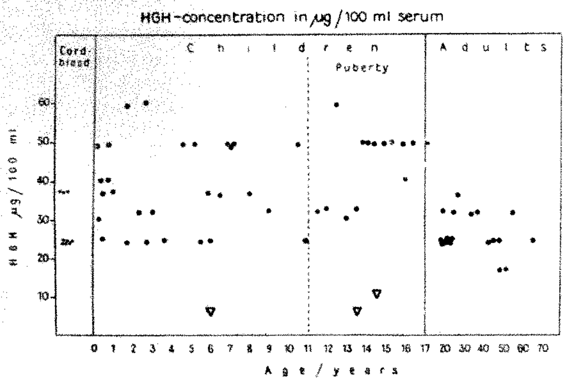

Fig. 2. ●, normal individuals; △, hypopituitary dwarfs

been treated with injections of growth hormone, showed a concentration of 10 µgm./100 ml. after treatment had been discontinued for 10 days.

Our findings for the growth hormone content in normal human serum correspond with the values given by Read (16–64 µgm./100 ml.). The content in the samples of cord-blood also falls in the range reported by him (24–48 µgm./100 ml.). In our three hypopituitary dwarfs the concentrations of growth hormone were a little higher than Read found in a similar group, but they still are clearly below the normal range.

Whereas Read believes that there is no difference in the content of serum between children and adults, our mean values for children are significantly greater than the mean concentration in adults. Investigations are under way to settle the question of the suggestive increase in the concentration of human growth hormone during puberty.

SPERMATOCYTOGENESIS WITH POSSIBLE SPERMIOGENESIS OF GUINEA PIG TESTICULAR CELLS GROWN *IN VITRO*

By DR. RUSSELL T. JORDAN, SEYMOUR KATSH* and NADIA de STACKELBURG

Department of Experimental Immunology, National Jewish Hospital at Denver, and Department of Pharmacology*, University of Colorado School of Medicine, Denver

SPERMATOGENESIS has been described as having two phases. In the first phase, spermatocytogenesis, the germ cells undergo repeated mitoses and meiosis followed by structural changes which give rise to a new type of cell, the spermatid. In the second phase, spermiogenesis, the spermatids undergo a series of complex transformations which result in the formation of mature spermatozoa.

In general the three cell types of the testes considered of major importance in spermatogenesis are the spermatogenic or germ cells, the Sertoli or sustentacular cells, and the interstitial or endocrine cells. Recently, we have been able to propagate testicular cells continuously in culture and have identified these three cell types by morphological and histochemical methods. Moreover, it appears that spermatogenic cells in culture retain the maturation potential needed to form spermatids and possibly spermatozoa *in vitro*.

In experiments reported elsewhere[1] it was shown that testicular cells continuously propagated in cell culture contain antigen(s) required to induce experimental allergic aspermatogenesis in the guinea pig and that testicular cells carried through several fluid transfers continued to synthesize antigen(s) which react (Schultz-Dale) with sensitized ilea of guinea pigs in which allergic aspermatogenesis has been induced.

The purpose of this article is to describe the cytological characteristics of testicular cells grown in cell culture.

Testes were aseptically removed from mature albino guinea pigs, washed in warm (37° C.) *tris*-buffered saline and stripped of the tunica vaginalis. The testes were minced with scalpel blades and treated with 0·25 per cent trypsin in *tris*-buffered saline at 37° C. for 2–3 min. After trypsinization the cells were diluted with 10 vol. of cold *tris*-buffered saline to stop the action of trypsin, centrifuged at 2,500 r.p.m. for 3 min. and re-suspended in nutrient medium to a final concentration of approximately 2×10^6 cells/ml. 10 ml. of the cell suspension were used to seed each culture.

The culture medium contained Earle's saline, 'Millipore'-filtered horse serum, lactalbumin hydrolysate, chick embryo extract, a complex vitamin mixture and antimicrobial agents. Glutamine was added to the cultures immediately before cultivation.

Cells were transferred by treating the parent culture at 37° C. for 3–5 min. with 0·25 per cent trypsin in *tris*-buffered saline. After trypsinization cells were washed once with cold *tris*-buffered saline and re-suspended in warm medium so that each screw-capped milk dilution bottle received 10 ml. containing approximately $2 \cdot 0 \times 10^5$ cells. Cells were grown in a humidified incubator at 37° C. in an atmosphere of 10 per cent carbon dioxide and 90 per cent oxygen.

Single cells for photomicrographic and histochemical analysis were obtained by diluting cell suspensions to approximately 5 cells/ml. 1 ml. was placed in a Petri dish containing several coverslips. After

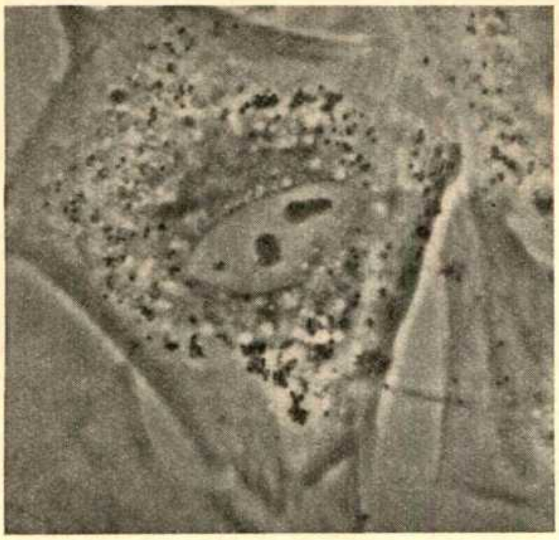

Fig. 1. Sertoli cell in culture 37 days. Phase contrast (× 1,188)

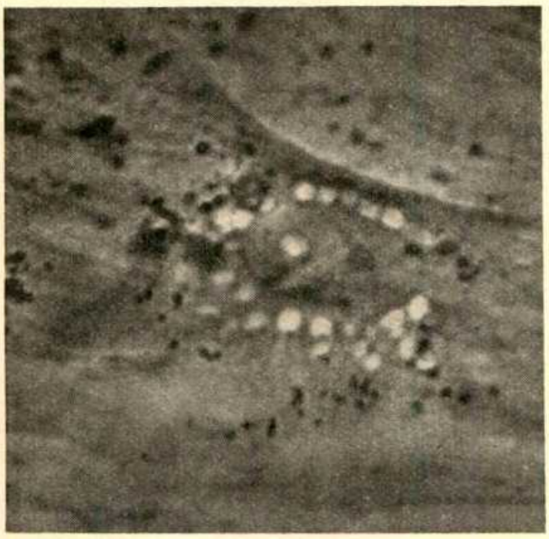

Fig. 2. Interstitial cell after 3 *in vitro* transfers: in culture 18 days. Phase contrast (× 250)

attachment to coverslips, cells were examined by phase microscopy or stained and photographed. Morphological and histochemical criteria used in identification of the different cell types were those already described and confirmed by others for the intact testis[2-6]. Coverslip preparations were fixed in 10 per cent neutral formalin for 8–10 hr. A triple stain for deoxyribonucleic acid, polysaccharides and proteins was used for differentiating between spermatogenic cells and other cellular components of the testes[7]. The nuclei stained blue to green, the mucus (polysaccharides) and structures in the Golgi zone, red; and the cytoplasm yellow. Thus the 'idiosomic' granules of the Golgi region in the primary and secondary spermatocytes, which later fused to form the 'acrosome' and 'head cap' of the spermatids, could be followed through various stages to the mature sperm by the bright red staining properties of the polysaccharide[3,5,6].

Fig. 1 is a coverslip preparation containing an epithelial-like cell with an ovoid nucleus and three nucleoli. The nuclear membrane is clearly outlined and the reticular cytoplasm contains fibrillar mitochondria, chromatin granules and lipoid droplets. This cell type is characteristic of the Sertoli cell and retains its morphological and histochemical properties during repeated passage in culture. Multiplication of the Sertoli cell *in vitro* results in a 'Sertolian syncytium' or a confluent growth connected by protoplasmic bridges.

Fig. 2 is a coverslip preparation of an epithelioid cell which contains a slightly elongated nucleus. The cytoplasm is highly granular and contains various inclusions. The perinuclear cytoplasm contains highly refractive, discrete, round globules, fairly uniform in size, which react positively when tested for neutral fats and lipoids. This cell type characteristic of the interstitial cell has been described in detail by Rasmussen[2].

The large spherical or oval cell type seen in Fig. 3 grew as a free-form, unattached, monodispersed cell suspended in the growth medium and contained a spherical mass close to the nucleus which stained red and is characteristic of primary and secondary spermatocytes. Primary spermatocytes (Fig. 3, *A*) are the largest of the developing germ cells. Secondary spermatocytes (Fig. 3, *B*, *C*), derived from the primary spermatocytes by the first reduction division, are somewhat smaller than the primary and generally the chromatin is less dense. Cells *B* and *C* have resulted from the division of what appears to have been a primary spermatocyte similar to *A*. Each of these secondary spermatocytes presumably will undergo complex structural changes to form spermatids.

Fig. 4 contains a group of cells, one of which (*A*) appears to be in early metaphase with tetrads typical of meiosis. The structures in this cell suggest the occurrence of parasynapsis with the organization of paired homologous chromosomes and the formation of quadripartite tetrads of chromosomal configurations. The presence of this cell distinctly separates meiosis *in vitro* from mitosis. *B* appears to be a spermatid flattening at the beginning of the maturation phase with the acrosomic granule transformed into a cone. The tadpole-like structure

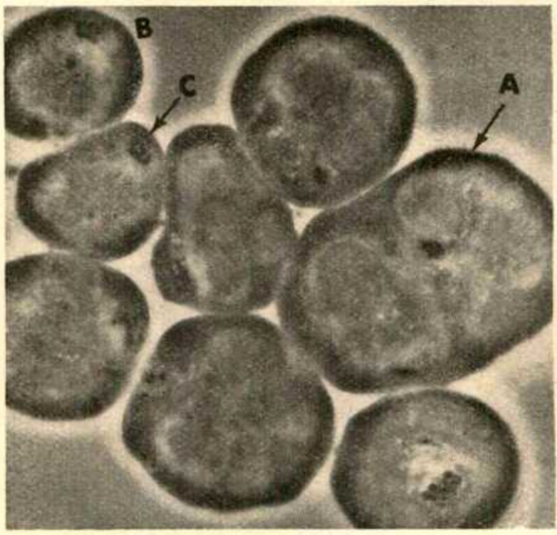

Fig. 3. Primary and secondary spermatocytes growing in supernatant fluid after 3 *in vitro* transfers; in culture 35 days. Phase contrast (× 1,188)

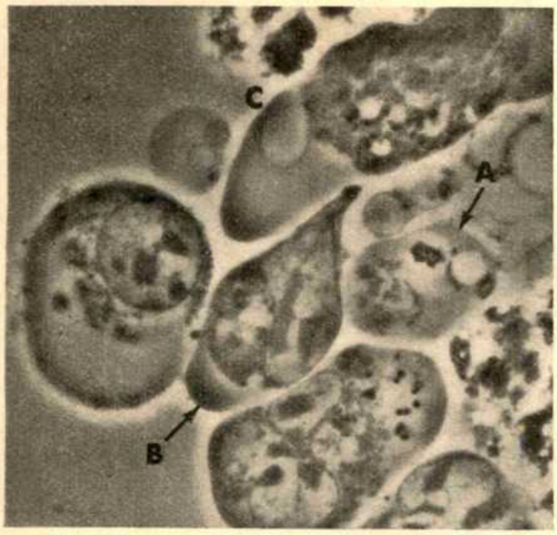

Fig. 4. A cell in meiosis (*A*) and spermatids in different stages of formation after 3 *in vitro* transfers: in culture 35 days. Phase contrast (× 1,188)

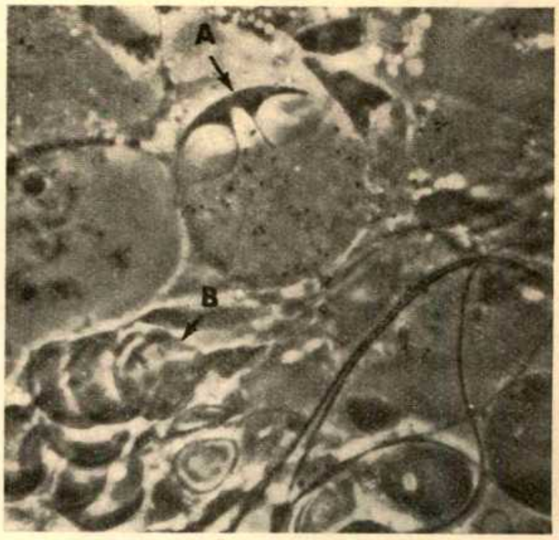

Fig. 5. Structures which appear to be mature and immature spermatozoa. Phase contrast (× 1,188)

(Fig. 4, *C*) is a spermatid with a profile view of the head cap.

In Fig. 5, *A* is a round cell which appears to contain the hollow heads of two sperms, while at the lower left portion of Fig. 5 are structures which appear to be mature sperm.

These findings show that spermatogenic, sustentacular and interstitial cells of the testes continuously propagated in culture retain their morphological and histochemical characteristics in addition to their immunological properties[1]. Moreover, it appears that spermatogenic cells carried in culture undergo metamorphosis to form mature sperm. It is important to know in such work as this whether spermatogenic cells taken from the testes were in an advanced stage of development and merely 'matured' into spermatozoa in culture or whether immature spermatogonia underwent all the necessary transformations to form mature sperm. This problem is now being investigated by time-lapse cinematography.

This work was supported by funds from grant *CY*–5188, National Institutes of Health and the Population Council, New York.

FORMATION OF DIFFERENT HÆMOGLOBINS IN TISSUE CULTURE OF HUMAN BONE MARROW TREATED WITH HUMAN DEOXYRIBONUCLEIC ACID

By PROF. LORRAINE M. KRAUS
School of Biological Sciences, University of Tennessee Medical Units,
Memphis, Tennessee

ALTHOUGH transformation of bacteria is an established fact, the transformation of mammalian cells is in a pioneering phase of research. In order to accomplish transformation, isolated deoxyribonucleic acid (DNA) must cross the cell membrane and become part of the genetical apparatus of the cell, thereby regulating the production of a substance within that cell which was absent before entry of DNA. It has been demonstrated[1] that intact DNA enters the mammalian cells and does become part of the nuclear material. The presence of a substance in the cell synthesized as a direct result of the new DNA is more difficult to demonstrate. In the human hæmoglobins each polypeptide chain synthesized is directly related to the presence of a gene or sequence of DNA in the chromosomes of the erythrocyte precursors. This was demonstrated by Itano and Robinson[2]. Incorporation of DNA from cells producing one type of hæmoglobin into cells which produce another kind of hæmoglobin should allow the detection of a new hæmoglobin in the cells into which the DNA has been incorporated. Production of hæmoglobins not previously present in tissue culture following incorporation of DNA into the erythrocytic series of cells has been accomplished here. These new hæmoglobins contain the polypeptide chains α^A, β^A, β^S, γ and probably an altered α-chain.

Bone containing red marrow obtained at surgery from an individual, homozygous for hæmoglobin *A*,

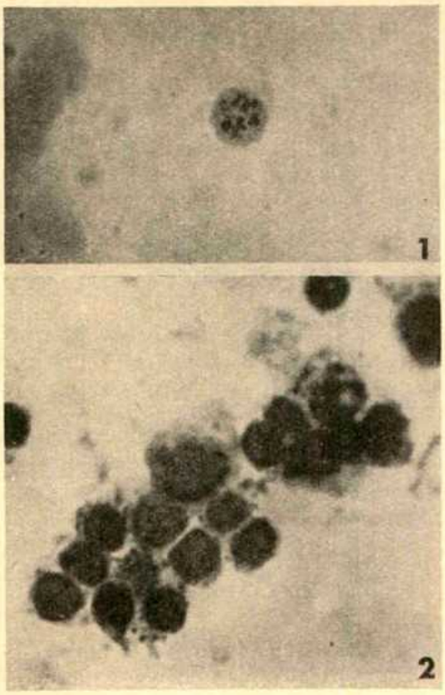

Fig. 1. Autoradiogram using Kodak '*AR* 10' stripping film. Exposure, 41 days. Stained with Wright-Giemsa. 1, mitotic figure showing incorporation of tritiated thymidine into the chromosomes of cells from bone from an individual with hæmoglobin *A* after 4 days of tissue culture. 2, group of prorubricytes and rubricytes showing incorporation of tritiated DNA into cytoplasm and nucleus of bone marrow from a sickle-cell anæmia patient after incubation for 24 hr. with tritiated DNA

was incubated in Tyrode solution containing 10 per cent of the patient's plasma. Methyl-labelled tritiated thymidine, 500 μc. in 0·02 mgm./0·5 ml. (New England Nuclear Corp.) was added to the tissue culture. After maintaining the tissue culture at 27° C. for four days, autoradiograms of the marrow cells were prepared using Kodak '*AR* 10' stripping film (Fig. 1, 1). DNA was extracted by the salt extraction method used by Spizizen[3]. The extracted DNA gave typical absorption spectra[4] and the concentration calculated by $E_{1\,\text{cm.}}^{1\%} = 192$ at 260 millimicra was 1 μgm./μl. Nine hundred μgm. of DNA were added to bone marrow obtained by sternal puncture from a patient with sickle-cell anæmia. The hæmoglobin present was homozygous hæmoglobin *S* with 8 per cent fœtal hæmoglobin. This bone marrow and the added DNA were maintained in tissue culture for 10 days at 27° C. in a sealed culture dish in Tyrode solution containing 10 per cent of the patient's plasma. A plasma clot formed during the course of the incubation. Cells were removed at 16, 24 and 48 hr. after the addition of DNA and slides were prepared with Kodak '*AR* 10' stripping film for autoradiographical examination. All autoradiograms showed incorporation of the tritium-labelled DNA into the cytoplasm or the nucleus of nucleated erythrocytes (Fig. 1, 2), and into some other marrow cells. After 10 days, an aliquot of patient's plasma labelled with iron-59 as ferrous chloride was added and the tissue culture was incubated under continuous shaking in a water-bath at 37° C. for 1·5 hr. The cells were washed with Tyrode solution and a hæmolysate prepared which was fractionated by electrophoresis in *p*H 8·6 veronal buffer. The total hæmoglobin component was found to be labelled with iron-59 and contained 45 per cent of the total radioactivity on the paper strip. The specific activity was 100 counts/min./mgm. of hæmoglobin. These results agree well with previous experiments reported in ref. 5. This demonstrates that at the end of 10 days of tissue culture the erythrocyte cells were capable of synthesizing labelled hæmoglobin.

Electrophoresis was used to compare the cell hæmolysate from the tissue culture of DNA-treated cells with the cell hæmolysates from peripheral blood of the individual homozygous for hæmoglobin *A* (source of the DNA) and the patient with homozygous hæmoglobin *S* with 8 per cent hæmoglobin *F* (the original tissue culture). The results are in Table 1.

Fig. 2 depicts the results of agar electrophoresis showing the different hæmoglobins formed in tissue culture treated with DNA.

Electrophoresis in 7 *M* urea–0·1 *M* veronal buffer at *p*H 8·2 separates the polypeptide chains of hæmoglobin[6]. This method was used to separate the polypeptide chains of the new hæmoglobins, hæmoglobin *A* and hæmoglobin *S–F* found in the cell hæmolysates (Fig. 3). The identification of the

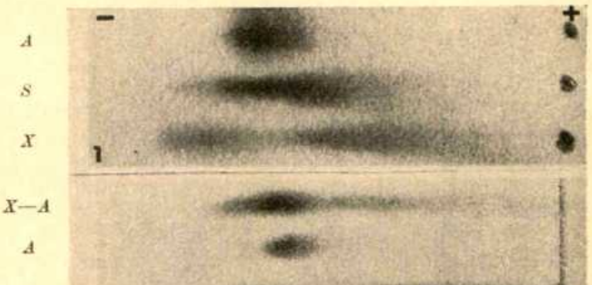

Fig. 2. Agar electrophoresis of cell hæmolysates from tissue culture treated with DNA, labelled *X*, from peripheral blood of the sickle-cell anæmia patient. labelled *S* (original bone marrow tissue culture) and of an individual with hæmoglobin *A*, labelled *A* (source of DNA). All material was in the form of cyanmethæmoglobin and was of equal concentration. 1, 2, 3, *tris*-EDTA-boric acid *p*H 7·1; 4, *tris*-citric acid *p*H 6·1; 5, *tris*-EDTA-boric acid *p*H 8·6. The origin is designated by a pencil mark. Stained with bromphenol blue

polypeptide chains present in the cell hæmolysates was accomplished by electrophoretic comparison with purified α^A, β^A, β^S and β^C polypeptide chains isolated by countercurrent distribution[9].

The absorption spectra in the range 200–700 mμ for all the above cell hæmolysates were superimposable and typical for oxyhæmoglobin containing a small amount of methæmoglobin.

From the results of these experiments it appears that cells which were genetically determined to synthesize only α^A, β^S and γ polypeptide chains of hæmoglobin, on incorporation of the genetical material (DNA) from cells which synthesized only α^A, β^A and γ polypeptide chains, now are able to synthesize the originally present α^A, β^S and γ polypeptide chains and in addition β^A and possibly an altered α polypeptide chain. These polypeptide chains in the cells altered by DNA combine to form two hæmoglobins differing electrophoretically from hæmoglobins *A*, *S* and *F*.

NORMAL adult hæmoglobin (Hb-*A*) consists of two α^A-polypeptide chains joined to two β^A-polypeptide chains and has a molecular formula $\alpha_2^A\beta_2^A$ (ref. 1). Most human hæmoglobin variants, as well as fœtal hæmoglobin, $\alpha_2^A\gamma_2^F$ (refs. 2, 3), and hæmoglobin A_2, $\alpha_2^A\delta_2^{A_2}$ (refs. 4, 5), have the same type of structure. Two hæmoglobin variants have been described which do not contain α-chains, namely, hæmoglobin *H*, β_4^A (refs. 6–8) and hæmoglobin

* Beit Memorial Fellow.

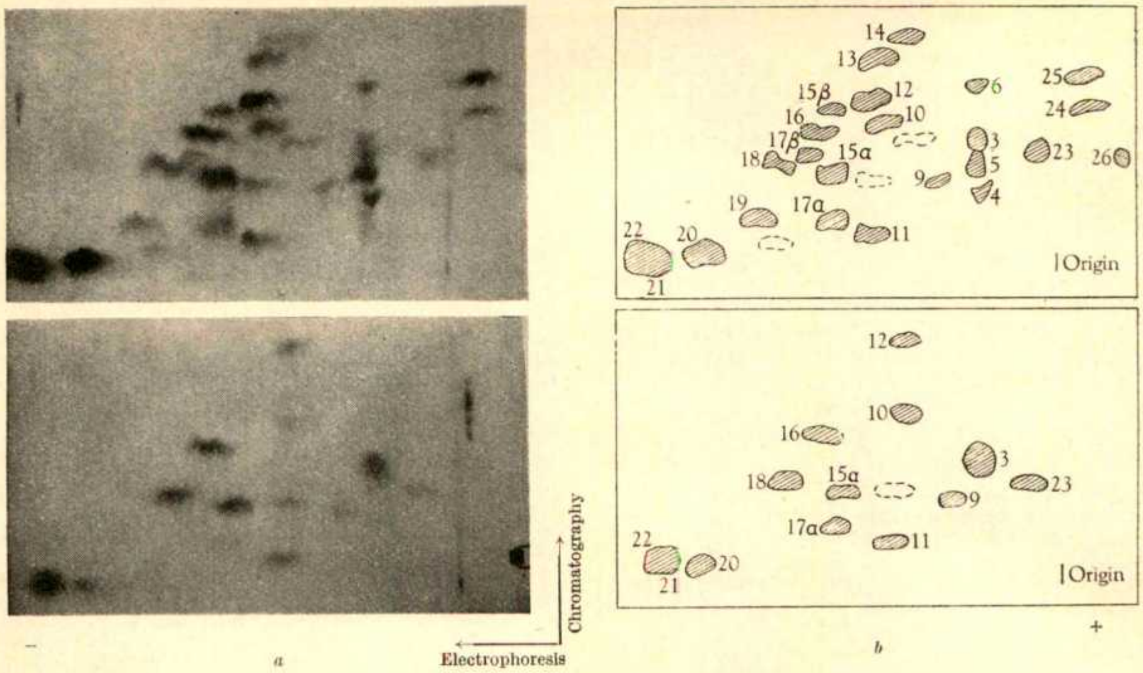

Fig. 1. Analysis of peptides obtained by tryptic hydrolysis of (top) Hb-*A* and (bottom) Hb-α^A; electrophoresis in pyridine, acetic acid, water (90 : 0·4 : 10), *p*H 6·4, followed by ascending chromatography in isoamyl alcohol, pyridine, water (35 : 35 : 27). (*a*) Photographs of peptide pattern stained with ninhydrin; (*b*) tracings of peptide pattern (Method and numbering system as ref. 28)

'Bart's', γ_4^F (refs. 9–11). In this report, the properties of a hæmoglobin, now called hæmoglobin α^A (Hb-α^A), consisting of a single α^A-chain, are described.

Hb-α^A was prepared by eluting purified Hb-*A* from a column of carboxymethyl cellulose using an 0·3 *M* sodium acetate buffer of *p*H 4·7, dialysing the eluted hæmoglobin solution back to a neutral *p*H and then separating the resulting hæmoglobin mixture by starch block electrophoresis[12,13]. In phosphate buffer of *p*H 7·0 and [Na⁺] 0·08 *M* Hb-α^A migrated more rapidly towards the cathode than Hb-*A*.

Fig. 1 compares the peptides obtained from the tryptic digestion of Hb-α^A with those obtained from Hb-*A*. It can be seen that those peptides, namely, 4, 5, 6, 12, 14, 15β, 17β, 19, 24, 25 and 26, arising solely from the β^A-chain of Hb-*A* are absent. In contrast, peptides 3, 9, 10, 11, 13, 15α, 17α, 18 and 23 which originate from the α^A-chain appear in the 'fingerprint'. Hb-α^A was also dissociated and recombined[14,15] with canine hæmoglobin, hæmoglobin *G*/*C* and hæmoglobin *I*. In the recombination experiment with canine hæmoglobin, only the slower of the two new species which form in the recombination of canine hæmoglobin with Hb-*A* was observed (Fig. 2). This species is known to have the composition $\alpha_2^A\beta_2^{Can.}$ (ref. 16). When Hb-α^A was recombined with hæmoglobin *G*/*C*, $\alpha_2^G\beta_2^C$ (ref. 17), the only new species formed was hæmoglobin *C*. On the other hand, it is known that when hæmoglobin *G*/*C* is recombined with Hb-*A*, both hæmoglobins *G* and *C* form[17] according to the equation:

$$\underset{\text{Hb-}G/C}{\alpha_2^G\beta_2^C} + \underset{\text{Hb-}A}{\alpha_2^A\beta_2^A} \rightarrow \underset{\text{Hb-}G/C}{\alpha_2^G\beta_2^C} + \underset{\text{Hb-}C}{\alpha_2^A\beta_2^C} + \underset{\text{Hb-}G}{\alpha_2^G\beta_2^A} + \underset{\text{Hb-}A}{\alpha_2^A\beta_2^A}$$

Thus, the appearance of hæmoglobin *C* but not hæmoglobin *G* in this experiment as well as the formation of the species $\alpha_2^A\beta_2^{Can.}$ but not the species $\alpha_2^{Can.}\beta_2^A$ in the recombination with canine hæmoglobin suggest that the new hæmoglobin consists solely of α^A-chains. Recombination of Hb-α^A with hæmoglobin *I* produced only Hb-*A*, confirming the presence of α^A-chains in Hb-α^A. This experiment is analogous to the recombination of hæmoglobin *H* with a hæmoglobin possessing abnormal β-chains[18,19]. In the latter, hæmoglobin *H* donates β^A-chains which combine with the α^A-chains of a β-chain variant to form Hb-*A*, while in the experiment reported here Hb-α^A donates α^A-chains for the formation of Hb-*A*, this time with the β^A-chains of an α-chain variant.

The sedimentation properties of Hb-α^A (ref. 20) resemble closely those of sperm whale myoglobin and the hæmoglobin of the brook lamprey, *Lampreta fluviatilis*. Thus, the value of 1·7 *S* for the sedimentation coefficient of Hb-α^A may be compared with the figure of 1·7 *S* for myoglobin determined under the same experimental conditions, or of 1·8 *S* quoted for lamprey hæmoglobin[21]. Moreover, the molecular weight of Hb-α^A, 17,000 ± 1,000, is similar to the value of about 18,000 for myoglobin and 17,200 for lamprey hæmoglobin[21] and is near the molecular

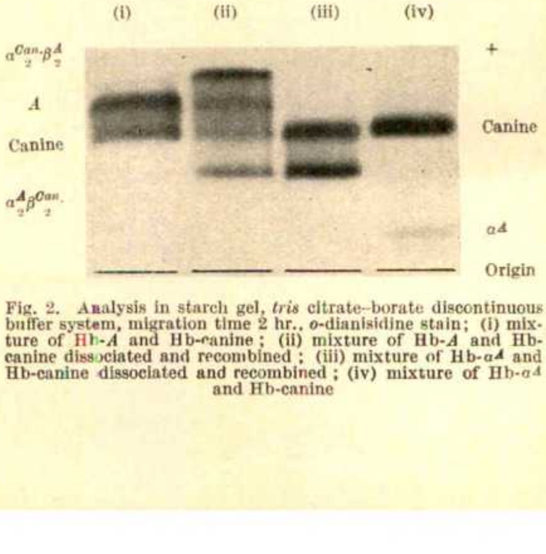

Fig. 2. Analysis in starch gel, *tris* citrate–borate discontinuous buffer system, migration time 2 hr., *o*-dianisidine stain; (i) mixture of Hb-*A* and Hb-canine; (ii) mixture of Hb-*A* and Hb-canine dissociated and recombined; (iii) mixture of Hb-α^A and Hb-canine dissociated and recombined; (iv) mixture of Hb-α^A and Hb-canine

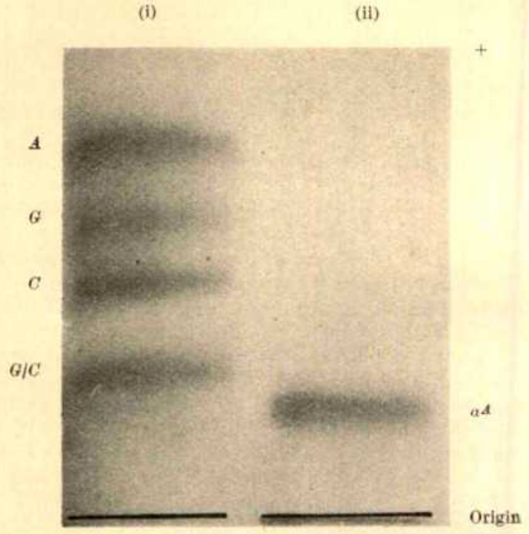

Fig. 3. Analysis in starch gel, *tris* citrate–borate buffer system, migration time 2 hr., *o*-dianisidine stain; (i) hæmolysate containing Hb-*A* + *G* + *C* + *G*/*C*; (ii) Hb-α^A

weight expected for the α^A-chain on the basis of its amino-acid composition[22,23]. Hb-α^A therefore consists of a single α^A-polypeptide chain.

The absorption characteristics of the cyanmet-derivative of Hb-α^A are, with one exception, identical to those of Hb-*A*. The one difference is found in the wave-lengths of the maximum of the 'protein' band which are at 274 mμ for Hb-*A* and at 270 mμ for Hb-α^A. This shift to lower wave-lengths would, however, be expected for a hæmoglobin consisting only of α^A-chains since the latter have a significantly higher tyrosine : tryptophan ratio than the globin of Hb-*A* itself.

Hb-α^A has a distinctive electrophoretic mobility, migrating nearer to the cathode than hæmoglobin *G*/*C* at *p*H's between 7·0 and 8·7 (Fig. 3). It is stable in solution, either as the carbonmonoxy or cyanmet-derivative, for a week at 4° C., but gradually precipitates on longer storage. When deep-frozen at − 15° C. it precipitates almost completely from solution in 48 hr.

These experiments have, therefore, shown that a hæmoglobin consisting of a single α^A-chain is capable of separate *in vitro* existence. Moreover, its electrophoretic mobility and stability in solution are such that if it occurred *in vivo*, even in small amounts, it would be detected by starch-gel electrophoresis either in the *tris* citrate–borate system at *p*H 8·7 (ref. 24) or in phosphate buffer[15,25,26]. Starch-gel analyses of fresh hæmolysates from a number of individuals, normal or with hæmoglobinopathies or thalassæmia, carried out by us have failed to reveal any such component. However, it is probable that small amounts of this hæmoglobin are formed in some recombination experiments, particularly if prolonged acid treatment is used. The only other hæmoglobin with an electrophoretic mobility slower than hæmoglobin *G*/*C* is hæmoglobin Gower 2, found in the red cells obtained from a small human fœtus[27]. However, the position of the tryptophan fine structure band of the latter hæmoglobin is at 2902 Å. which is significantly shorter than that found for Hb-α^A and these two hæmoglobins are therefore not the same. It would thus appear that Hb-α^A does not occur *in vivo* and this is of some importance in any consideration of the synthesis of the hæmoglobin molecule.

This investigation has been supported by a grant from the Colonial Medical Research Committee and also by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council.

We are indebted to Miss Jean Atwater for a sample of a hæmolysate containing hæmoglobin *I* and to Dr. A. Edmundson for a specimen of crystalline sperm whale myoglobin.

TELEVISION MICROSCOPY

A Flying-spot Interference Television Microscope

AN all-electronic flying spot interference television microscope for the rapid determination of cellular dry mass has been developed in this laboratory. The work has stemmed from the suggestions of Barer[1] and from consultation with F. F. Roberts and F. Smith of C. Baker Instruments, Ltd.

The interferometric technique of dry-mass determination has been well documented[2] and mechanical systems of scanning have been developed[3].

The equipment developed in this laboratory uses the flying-spot technique of scanning. A low-speed system with 10-sec. sweep is used in order to improve the ratio of signal to noise and to ease the requirements on the computing circuitry. The system consists of the flying-spot scanner tube, interference microscope, multiplier phototube, and a photoformer for the continuous solution of the intensity-phase angle equation. A monitor presents a picture of the photoformer output, which represents the relative phase angle present in the cell and, therefore, the dry mass of the various portions of the cell on a grey scale. The photoformer output is fed to an integrator circuit which sums the phase angle in the entire field. The integration output at the end of each sweep, therefore, represents the total dry mass present in the optical field. The information from the integrator is continuously read out on a strip chart recorder.

Auxiliary pulse generating equipment is so arranged that the integrator may be made to sum only the information in a selected area of the field. The area being integrated is indicated on the monitor by brightening. This area may be a square or rectangle with a minimum size of about 2μ at the magnification at present used.

The grey scale dry-mass images of the living cell may be continuously recorded on 16-mm. motion picture film. When such a film is presented at a speed of 16 frames per sec. a time-lapse motion picture is obtained.

This system has several advantages over previously described techniques. (1) The data on the dry mass of whole cells or segments of cells are obtained and recorded by two methods every 10 sec. (2) The dry-mass images of the specimen are continuously displayed on the monitor tube during the course of the experiments. (3) The visual presentation of the dry-mass image makes the positioning of the brightened area of the raster quite easy and this permits continuous determination of the dry mass of selected areas of the cell.

This work was supported by grants from the Atomic Energy Commission, the Southwestern Medical Foundation, the Damon Runyon Memorial Fund, and Tobacco Research Industry Committee.

Ultra-Violet Television Microscopy

SEVERAL attempts to use ultra-violet-sensitive television cameras in association with ultra-violet microscopes to give an immediate display of the image have been reported[1]. From published photographs the sensitivity and image quality do not appear to be very high and results obtained with other types of image converters have also been disappointing. A newly developed E.M.I. 'Vidicon' camera tube incorporating a quartz window and a specially modified arsenic triselenide target layer appears to be very promising. The spectral response curve has a peak at 4000 Å. with a half-intensity band-width of about 1500 Å. The sensitivity at 2537 Å. is approximately 0·10 μamp./μW./cm.[2]. This appears to be several times higher than previously reported values. The layer has unity gamma and reasonably low inertia.

This tube has been used in conjunction with quartz objectives and condenser, illuminated with monochromatic light of wave-length 2537 Å. from a low-pressure mercury lamp and simple monochromator. With a signal current of between 0·05 and 0·1 μamp., excellent images of living cells at magnifications of 3,000 times could be displayed on a television screen. The intensity of illumination was adequate even with the glycerine immersion objective of N.A. 1·25 and it was possible to take good-quality photographs of the screen using a 35-mm. camera with exposures as short as 1/25 sec. The great advantage of the system is that it enables microscopy to be carried out as easily with ultra-violet as with visible light. Focusing presents no problem and there are no special mechanical requirements. The lenses were mounted on a simple student-type microscope stand. Many fields containing large numbers of cells can be scanned in a short time and the very shallow depth of field makes it possible to focus the different levels through a relatively thick specimen, thus helping to build up a three-dimensional impression.

In this connexion the technique of immersion refractometry[2] has been adapted for ultra-violet work. The lens-like behaviour of an uncompressed spherical cell makes observation of internal structures difficult. This can be partly overcome by immersing such cells in a suitable protein medium having a refractive index approaching that of the cytoplasm. This method has enabled the structure of chromosomes to be seen very clearly in undamaged cells. Since, however, the cytoplasm of most cells shows some degree of absorption at 2537 Å. it is difficult to bring about actual reversal of contrast by immersion in protein alone. If a little nucleic acid is added to a less-concentrated protein solution it becomes possible to match the cytoplasm exactly against the surrounding medium or to make it appear bright instead of dark. This method opens up the possibility of measuring both the refractive index and absorption of living cells in the ultra-violet to obtain quantitative cytochemical information. It also makes it possible to vary at will the contrast of internal detail, a technique referred to elsewhere as "optical dissection"[2]. Finally, the method offers considerable promise for rapid microspectrophotometry. It is quite simple to scan any line across the image of a cell and display a light intensity curve on an oscilloscope screen. There is no difficulty in principle in converting such curves to an optical density scale and in feeding the results to an electronic integrator to measure the total mass of absorbing material.

We wish to thank E.M.I. Electronics, Ltd., for the loan of television equipment and Cooke, Troughton and Simms, Ltd., for the loan of optical equipment.

LETTERS TO THE EDITORS

SPACE SCIENCE

Interaction of West Ford Needles with the Earth's Magnetosphere and their Life-time

THE life-time of the copper needles which were to be placed in orbit for the West Ford experiment is a matter of great concern. It is generally believed that the pressure of solar radiation (*not* drag) will bring the needles down in about seven years provided they are launched into a 'resonant' orbit (for example, a polar orbit at altitude 3,800 km.); for a good description of the resonance effect, see I. I. Shapiro and H. M. Jones[1]. These authors also show that if the semi-major axis of the orbit is changed by more than 150 km., the resonance would be destroyed and the life-time greatly increased.

My earlier article[2] discussed the problem of the drag of a charged body moving through a plasma and considered also just how a body acquires an electric charge in space. Although originally applied to micrometeors, this work can be carried over directly to the West Ford dipoles, which are copper needles of length 1·77 cm., diameter $2 \cdot 8 \times 10^{-3}$ cm., and mass 10^{-4} gm. I calculate a capacity C of $1 \cdot 5 \times 10^{-13}$ farad (my earlier article[2] adopts the wrong value of capacity, and, through force of circumstances, went to press before I could correct it; all further results there must be changed in proportion).

A more detailed examination of the charging effects for the particular conditions of the magnetosphere where the needles are put in orbit still leads to a potential of the needles close to the value adopted earlier. Its 'effective' value is $- 3 \cdot 6$ V. Hence the nominal charge Z is $\sim 3 \times 10^6$ electrons.

A further detailed examination shows that within a small error it is permissible to replace the needle by a point charge when calculating its total interaction force with the magnetospheric plasma. Then with the use of the relations given earlier[2], the drag force acting on the needles turns out to be $F \sim 10^{-23} Z^2 n$ dyne, where n is the ion density $\sim 3 \times 10^3$ H^+ ions per cm.^{3} at the West Ford orbit. The resultant rate of decrease of the orbit radius is $\sim 3 \times 10^{-10} Z^2$ km. per annum. Hence the orbit shrinks at the rate of $dr/dt \sim 3 \times 10^3$ km. per annum.

The greatest uncertainty enters into the determination of the electric potential of the needle. I estimate it to be within $- 7 \cdot 2$ to $- 1 \cdot 8$ V., with a probability of more than 90 per cent. With these extreme limits the orbit would shrink at a rate as high as $1 \cdot 2 \times 10^4$ km. per annum (33 km. a day) or as low as 750 km. per annum.

It is clear, therefore, that not only will the drag spoil the resonance but also it will in all likelihood provide an upper limit for the life-time which amounts to a few months, possibly as much as three years.

However, one cannot entirely exclude the possibility that the root-mean-square potential is less than 0·25 V., leading to $dr/dt < 15$ km. per annum (in which case the radiation pressure resonance would be preserved and the life-time would be ~ 7 years); or that the root-mean-square potential is about 0·36 V., leading to $dr/dt \sim 30$ km. per annum, in which case the resonance would be destroyed and the life-time *increased* to nearly a century.

A detailed report has been prepared and will be published later.

PHYSICS

Lattice-type Vibrations in Associated Liquids and the Origin of Anomalous Rayleigh Scattering

WHEN a sample is irradiated with monochromatic light of frequency ν_0 and the scattered light at right angles to this incident beam examined by means of a spectroscope, a line spectrum is observed containing besides the Rayleigh component ν_0, the Raman lines $\nu_0 \pm \Delta E_i/h$, where ΔE_i are the energy differences between stationary states of the sample. Although an arc having a relatively isolated line is normally used as the source of monochromatic light, all arcs do give rise to some continuum and this also appears in the spectrum as Rayleigh scattering. This continuum can be reduced by a carefully designed arc (such as the Toronto type[1] mercury arc), while the Rayleigh scattering is minimized by preparation of the sample for investigation in an optically clean condition. However, even under such favourable conditions some continuous scattering does occur, but the fact that it appears to depend on the nature of the scattering medium, extending less than 100 cm.$^{-1}$ from the exciting line in the case of unassociated liquids[2–4] and their corresponding solids and many hundreds of cm.$^{-1}$ in the case of highly associated liquids[5] and solids, would suggest that it is not Rayleigh scattering as is often thought. Its origin is, therefore, of interest, and it is the purpose of the present communication to discuss the possible sources of these anomalous Rayleigh 'wings'.

Phonon scattering, giving rise to a Brillouin spectrum, can be quickly ruled out as the major cause of this broadening since the velocity of sound in liquids and solids is of the order of 10^5–10^6 cm.sec.$^{-1}$, corresponding to frequency shifts of only ~ 1 cm.$^{-1}$ at 4,000 Å.

In unassociated liquids and their corresponding solids, rotation of the molecules should give rise to broad wings on either side of the exciting line, the broadness of these wings depending on the rotational constant and the temperature, and in general being less than 100 cm.$^{-1}$ for all but very light molecules. This is normally believed to be the predominant cause of the Rayleigh wings in these systems[3,4,6]. Although in associated liquids and solids rotation of molecules

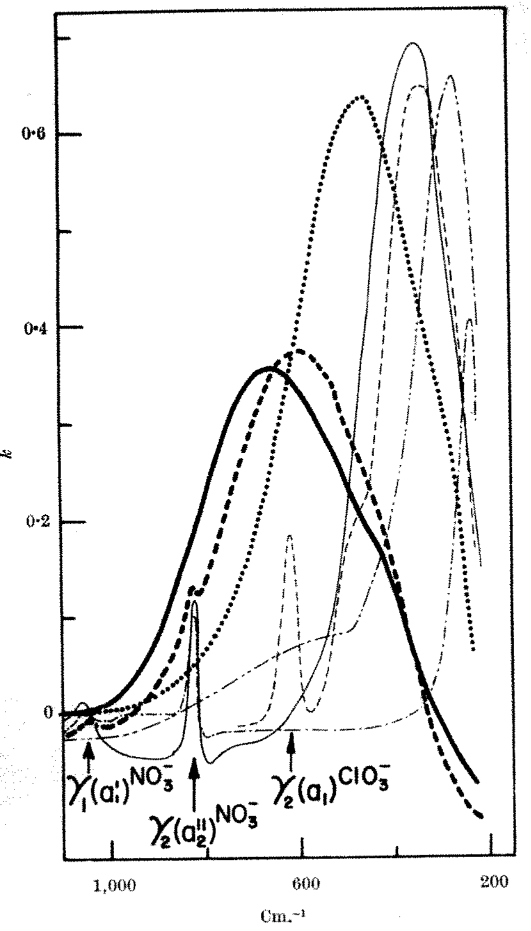

Fig. 1. The low-frequency infra-red spectra of some highly associated liquids. ▬▬, Water (20° C.); ■■■■, $LiNO_3$–H_2O (5·92 *M* at 20° C.); ————, $LiNO_3$ (313° C.); ·—·—·—, $NaNO_3$ (347° C.); – – – –, $LiClO_3$ (250° C.); ……, LiOH (490° C.); —··—··—, NaOH (350° C.). For both lithium and sodium hydroxides the ordinate scale should be multiplied by two

may still occur, the major cause of the Rayleigh wings probably arises from excitation of the optical modes of an associated or lattice-like structure. Such excitation of the optical modes may give rise to both a first- and a second-order Raman effect, the frequency maximum of the former corresponding roughly to that of the optical frequency observed in the infra-red, while the second-order Raman effect will extend out to approximately twice this frequency. Thus, solid sodium chloride, which has an infra-red absorption frequency[7] at 164 cm.⁻¹, exhibits a second-order Raman effect[8] extending out to 350–400 cm.⁻¹.

In the case of highly associated liquids, excitation of the optical branch of the quasi-lattice-like structure has not been reported previously. By using a one-angle reflexion technique[9] and an analysis due to Robinson and Price[10] the optical constants in the 200–1,000 cm.⁻¹ region have now been obtained for water, aqueous lithium nitrate, fused lithium nitrate, chlorate and hydroxide, and fused sodium nitrate and hydroxide, and the absorption spectra are shown in Fig. 1. The intense band in this low-frequency region can be assigned in every case to the excitation of the optical branch of a quasi-lattice, and the frequency of this band suggests that the Raman effect should show broad wings out to 400–900 cm.⁻¹ in fused salts and ~ 1,600 cm.⁻¹ in aqueous solutions, consistent with the known anomalous Rayleigh scattering in these systems.

It would appear of interest in the light of the above suggested origin of the anomalous Rayleigh wings to study this continuous scattering more fully, especially in the case of highly associated liquids. In this direction the 'laser', giving an intense monochromatic light source with no spurious arc continuum, should be ideal as a Raman source and should certainly clarify this question.

I wish to thank H. J. Bowlden for helpful discussion and criticism of the manuscript.

The Balance of Energy in Nuclear Fission

EARLY experimental observations on the range of fission fragments in air[1] suggested that the kinetic energy of fragments of nearly equal mass formed in fission (that is, symmetrical fission) was less than that of fragments of different mass (that is, in unsymmetrical fission), and very recent measurements[2] have clearly confirmed this, and shown that the deficiency amounts to about 30 MeV. (32,210 micromass units, μM.U.). The conservation of energy in fission may be expressed by an equation of the form:

$$\left({}^{A}_{Z}M\right) = \left({}^{A}_{Z_1}{}^{1}M\right) + \left({}^{A}_{Z_2}{}^{2}M\right) + E_{12} \qquad (1)$$

where ${}^{A}_{Z}M$'s are the masses of the fissioning nucleus and of the fragments, 1 and 2, of mass number A and charge Z, and E_{12} is the energy released expressed in mass units. This last appears as the kinetic energy of the fragments together with the neutrons and γ-rays emitted in fission. It has been shown[3] that the neutrons and γ-rays associated with symmetrical fission are not markedly greater in energy than those associated with unsymmetrical fission, and it appears that the deficiency in the kinetic energy in question must be associated with an excess in the masses of the unstable fragments. The masses of the unstable fragments formed initially in fission are not known, however, and attempts to predict them from present empirical mass formulæ have not shown the expected mass excess[4].

Koenig, Mattauch and Wapstra have recently compiled a consistent set of all known stable and unstable masses[5]. In this communication it is shown that an extrapolation of these known masses suggests

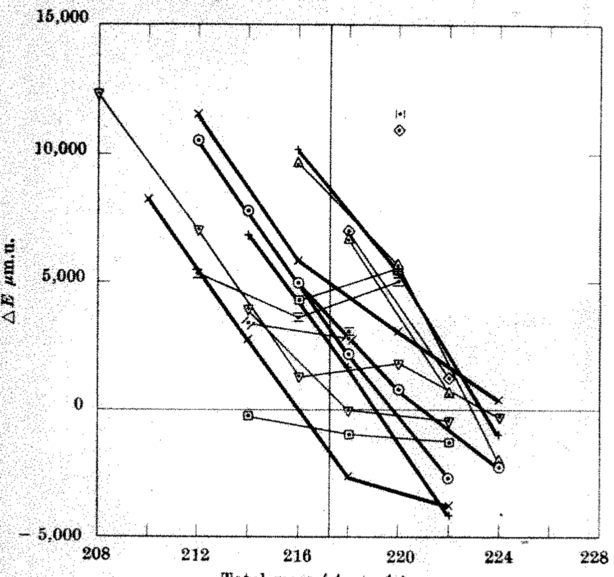

Fig. 1. Mass differences $({}_{54}Xe + {}_{38}Sr) - 2({}_{46}Pd)$

	$A_2 - A_1$	$(A_2^* - A_2) - (A_1^* - A_1)$
/·/	34	− 9·25
⌶	36	− 7·25
⊡	38	− 5·25
▽	40	− 3·25
×	42	− 1·25
⊙	44	+ 0·75
+	46	+ 2·75
△	48	+ 4·75
◇	50	+ 6·75
|·|	52	+ 8·75

that symmetrical fission fragments have greater mass than unsymmetrical fragments.

For symmetrical fission, (s), equation 1 may be written:

$$\left({}^{A}_{Z}M\right) = 2\left({}^{A_s}_{Z_s}M\right) + E_s \qquad (2)$$

From equations (1) and (2):

$$\left({}^{A_1}_{Z_1}M\right) + \left({}^{A_2}_{Z_2}M\right) - 2\left({}^{A_s}_{Z_s}M\right) = E_s - E_{12} = \Delta E \qquad (3)$$

No protons are lost in fission and, therefore:

$$Z_1 + Z_2 = 2Z_s \qquad (4)$$

and because the average number of neutrons in symmetrical fission is about equal to that from unsymmetrical fission:

$$A_1 + A_2 = 2A_s \qquad (5)$$

In Fig. 1, ΔE from equation 3 is plotted against the total mass with $Z_s = 46$ (for symmetrical fission of ${}^{236}_{92}U$), and $Z_1 = 38$, $Z_2 = 54$, for all the known masses (on the carbon-12 scale) subject to condition (5). Lines connect points for mass differences $(A_2 - A_1)$ for combinations of nuclides which differ by equal numbers of neutrons. Heavy lines show mass differences for combinations of nuclides which are nearly equally deficient in neutrons with respect to their most stable isotopes, that is, when:

$$(A_2^* - A_2) \simeq (A_1^* - A_1) \qquad (6)$$

where * indicates the most stable mass. The graph suggests that extrapolation of the heavy lines to a total mass of 236 (the mass of the compound nucleus before fission or neutron emission) would lead to combinations of nuclides with a high negative value of ΔE.

In Fig. 2 ΔE for the other combinations of Z_1 and Z_2 have been plotted for highly unsymmetrical to symmetrical combinations of nuclides. Values of A have here been chosen subject to conditions (5) and (6). Fig. 2 suggests that linear extrapolation to higher masses would lead to high negative values of ΔE only for the elements lanthanum to tellurium and their complements (atomic numbers 57–52 and 35–40). If such an extrapolation is valid, it may be associated with the observations that the symmetrical fragments and also the highly unsymmetrical fragments are formed in low yield and with low kinetic energy,

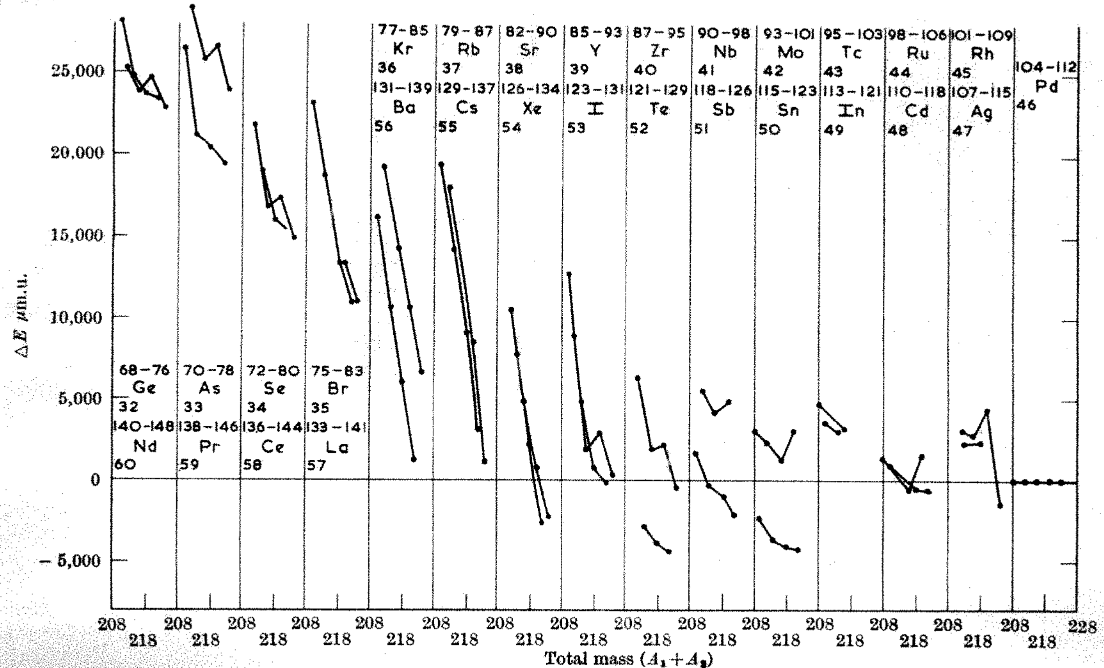

Fig. 2. Mass differences between unsymmetrical and symmetrical fragments

because there is less energy released in the formation of these fragments than in the formation of fragments with atomic numbers in the range shown. In addition, Fig. 1 gives a qualitative indication that the highest release of energy would occur in fission when nuclides are formed which are equally deficient in neutrons, and this is in accordance with the equal-charge displacement hypothesis for the distribution of charge in fission[6].

ENGINEERING

Non-Linear Transmission Lines for Millimetre Wave Generation and Reception

THE properties of non-linear transmission lines, containing, for example, ferroelectric material of the barium titanate class, have been examined in connexion with a computing system[1]. Their possible use as a variable capacity parametric amplifier element is obvious, and it has been shown recently that an electromagnetic shock-wave can be propagated[2]. This effect occurs when a signal of large amplitude is injected into the line. The high-field part of the wave travels at a greater speed than the low-field part so that a sine wave becomes a saw-tooth. After a certain time this has a vertical leading edge analogous to a shock-wave in a gas. Such a wave is rich in harmonics and a number of lines, driven with power derived from the same microwave magnetron and with outputs recombined through phase shifters, could be an efficient harmonic generator.

A less obvious method of generating higher frequencies with a non-linear line is as follows: Suppose a low-level microwave signal is fed into a wave-guide filled with ferroelectric, and that this guide is constructed so that it is possible to apply a d.c. bias voltage to change the permittivity of the dielectric. Suppose the signal pulse duration is for a certain time and that during this time the bias is changed so that the velocity of wave propagation increases. The emergent signal will then occupy a shorter time, but as it contains an unchanged number of oscillations the frequency will be increased. Also as energy is conserved the power will increase, if the losses can be neglected.

The contrary case, where the wave is slowed down during the pulse so that the pulse is stretched in time and reduced in frequency, is also of interest. In principle this would permit millimetre waves to be converted to a more easily detected frequency. These effects are large if the switching time of the bias voltage is of the order of the time taken by a wave to pass along the transmission line, which imposes some technical limitations.

However, the chief difficulty at present is in the ferroelectric material. Measurements at 10-cm. wavelength of permittivity variation with bias have shown that the effect is still appreciable in a barium–strontium titanate ceramic[3]. Measurements at 3-cm. wavelength showed that relative permittivities of several thousand are still obtained[4]. There appears to be no published work on these materials at higher frequencies and with d.c. bias applied.

I hope to make some measurements along the lines indicated in this communication at shorter wavelengths than 3 cm. As I have no facilities at present for material manufacture, these measurements will be initially with barium–strontium titanate supplied by an industrial research laboratory. I would be interested to hear from any organization producing titanates or the newer ferroelectric materials which would care to collaborate in a programme of millimetre wave measurements.

GEOLOGY

Carbonatitic Lava from Fort Portal Area in Western Uganda

IN an excellent paper Holmes[1] quotes chemical analyses of two spectacular carbonated lavas, one from the Katwe region, the other from Kalyango volcano near Fort Portal. In earlier work, Holmes and Harwood[2] described a similar carbonated lava from Lake Kyekora, also near Fort Portal. Present examination of a vesicular lava of high carbonate content poured out from Kalyango volcano shows close geochemical affinities with intrusive carbonatites. It must be emphasized that the lavas examined are fresh and unaltered and that the carbonated nature cannot be attributed to alteration after solidification. A proposed investigation of the numerous lavas in the Fort Portal field may elucidate the formation not only of the characteristic ultrabasic potassic volcanics of south-west Uganda and adjoining parts of the Congo, the petrogenesis of which Holmes has presented so admirably, but also the genesis of the carbonatites themselves.

The field relationships of the Kalyango and other similar 'carbonated' lavas have been described by Combe[3]. Extrusive equivalents of carbonatites are rare, one other occurrence being from Kerimasi volcano in Tanganyika[4].

A mineralogical, chemical and spectrographic investigation of the lava from Kalyango volcano shows the following characteristics: The rock is light-grey in colour, variably vesicular with phenocrysts of biotite up to 1 cm. across. It contains frequent inclusions of basement rocks and occasional rounded, possibly eclogitic fragments consisting of a dark-green clinopyroxene and pink garnet. The dense groundmass is powdered with magnetite and the vesicles are lined with a crust of small crystals of calcite and are often filled with spherules and rosettes of fibrous

2. Vesicular carbonatitic lava rich in zeolites, same locality. Total includes SrO = 0·60, BaO = 0·20, S = 0·40, F = 0·3.

(Analysis by O. von Knorring.)

zeolites. Under the microscope the ground-mass has a felt-like appearance containing minute grains of pyroxene, olivine, biotite, magnetite, some ilmenite, apatite and calcite. The larger clinopyroxene and biotite grains are seen to be corroded and the latter are often replaced by calcite along the cleavage. In polished sections magnetite and pyrite are the most conspicuous ore minerals. A partial analysis of magnetite showed some 11 per cent titanium dioxide; in reflected light, however, no exsolution lamellæ of ilmenite were seen. From partial analysis, the biotite is a magnesia-rich variety with a high titania content, and rather similar in composition to a biotite recorded by Combe and Holmes[5].

Among the major constituents of the lava (Table 1) silica and alumina are extremely low compared with other ultrabasic igneous rocks. Low silica contents of this kind are known in certain carbonate-rich alnöitic dyke rocks, for example in the so-called aillikite from Aillik Point in Labrador[6,7]. The calcium content is high, and most of the calcium is combined in silicates. The carbon dioxide content appears to be variable, and therefore lavas with even higher carbonate contents are possible, as shown by the almost pure carbonatite analysis by Holmes. Phosphorus, usually a minor constituent, is extremely high in the lava.

The pattern of the minor and trace elements is typical of carbonatite rocks. A feature common in some of these rocks is the dominance of strontium over barium, in addition to high lanthanum and niobium contents. In carbonatites the latter element often forms pyrochlore; in this case, however, a black, opaque perovskite in cubes 0·01–0·05 mm. across is believed to be the principal carrier of niobium.

The spectrographic results of the lava (Table 2) show, on one hand, similarities with rocks of the Toro-Ankole field, for example the katungites, and on the other close resemblance to carbonatites as determined by Higazy[8].

Table 2. SPECTROGRAPHIC ANALYSES OF CARBONATITIC LAVA FROM UGANDA (P.P.M.)

2.	14	—	250	30	25	50	12	85	800	550	7	600	45

(Analysis by Miss J. M. Rooke.)

A carbonatite magma, containing water and other volatiles like phosphorus, fluorine and sulphur, can effectively react with silicate rocks during intrusion through the sialic crust to produce the characteristic suite of rocks encountered among carbonatites and associated alkaline complexes. As a result of this interaction a part of the alkalis are released and may migrate to induce metasomatism in the country rock, as often expressed in the well-known phenomenon of fenitization. Selective concentration of alkalis in addition to differentiation may, moreover, result in sodium- and potassium-rich rocks.

The present carbonatitic lava provides further evidence for the magmatic nature of carbonatites and supports the hypothesis advanced by Holmes, that a carbonatite (magma or fluid) is instrumental in producing the remarkable group of volcanic rocks in south-west Uganda and the Congo.

We are indebted to Prof. W. Q. Kennedy for his interest in the work, Mr. A. Cawley, director of the Uganda Geological Survey, for permission to publish this communication, and to Miss J. M. Rooke for the spectrographic analyses.

CRYSTALLOGRAPHY

Structure of Molybdenum Sesquisulphide

THE existence of molybdenum sesquisulphide, Mo_2S_3, as a distinct phase has been in doubt for a considerable time. It was only in 1955 that McCabe[1] convincingly demonstrated the existence of the phase and obtained its X-ray powder pattern. An attempt to index the powder pattern has been made by Stubbles and Richardson[2]; they tentatively propose a tetragonal unit cell with $c = 10·9$ Å.; $c/a = 1·27$.

I have undertaken a new investigation of Mo_2S_3 by X-ray powder methods, using a Philips diffractometer. It was found that the true symmetry of the phase is monoclinic; the unit-cell dimensions are: $a = 8·633_5$ Å.; $b = 3·208$ Å.; $c = 6·092$ Å.; $\beta = 102·43°$. (Evidently, Stubbles and Richardson[2] were misled by the coincidence that a is almost exactly equal to $\sqrt{2} \times c$.) With a cell content of Mo_4S_6 the density is calculated as 5·806 gm./cm.^{3}.

The lines 010 and 030 are not observable in the powder diagrams, while 020 and 040 are very strong. Furthermore, the intensity sequence of the reflexions $h0l$ is found to be the same as that of $h2l$ and $h4l$; the same is true of $h1l$ and $h3l$. This indicates that Mo_2S_3 crystallizes in the space-group $P2_1/m$, with all atoms in the special position $2(e)$: $\pm (x, \frac{1}{4}, z)$. The intensity relations mentioned here made it possible to divide the intensities of the (not too numerous) pairs of coinciding powder lines. Thus, a complete set of experimental structure factors covering the copper-$K\alpha$ sphere was obtained and the structure could be determined by the usual methods.

A three-dimensional electron-density map is shown in Fig. 1. The sulphur atoms form a somewhat distorted close-packed lattice with layer sequence *chh*. The metal atoms are inserted in part of the octahedral holes of this lattice. The holes between neighbouring h-layers are completely occupied, while only half the

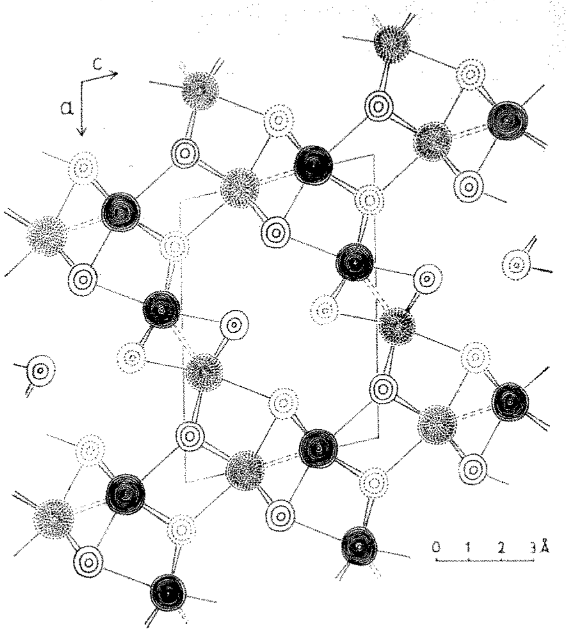

Fig. 1. Electron density of Mo_2S_3. Contours are at approximately 10 el./Å.^{3}. Full-line contours refer to atoms at $y = \frac{1}{4}$; broken contours to atoms at $y = \frac{3}{4}$. Mo—S bonds are indicated by full lines, the Mo—Mo chains by broken lines. The outlines of the unit cell are also indicated

holes between the other pairs of neighbouring sulphur layers are filled. Thus, the sequence of layers in the *a* direction is: . . S Mo S $Mo_{1/2}$ S $Mo_{1/2}$ S Mo S . . .

The molybdenum atoms are not in the centres of the sulphur octahedra; they are shifted by 0·32 Å. in the direction of one of the octahedron faces, in such a way that zig-zag Mo—Mo chains running in the *b* direction are formed. Within these chains the Mo—Mo distances are 2·85 Å., which is slightly longer than in the metal itself. Each molybdenum atom has three sulphur neighbours at distances of 2·36 Å. and three more at 2·57 Å. In MoS_2, where the metal is in trigonal-prismatic surroundings[3], the Mo—S distances are 2·35 Å.

I wish to thank the Climax Molybdenum Company of Michigan for a gift of pure Mo_2S_3. The assistance of Dr. C. F. van Bruggen and Mr. H. Schurer in this investigation is gratefully acknowledged.

CHEMISTRY

Incorporation of Trivalent Cations in Crystalline Potassium Chloride

DIVALENT metal halides such as calcium chloride, dissolved in alkali halide crystals, increase the ionic conductivity[1] and give rise to additional bands (the *Z* bands) in the absorption spectra of coloured alkali halides[2]. For some time there has been speculation concerning the possibility of incorporating trivalent cations and the effect of such additions on electrical and optical properties.

Little experimental information is at hand. Hayes and others[3–5] suggested, on the basis of paramagnetic resonance studies, that sodium fluoride grown from a melt with added chromium chloride contained the chromium as Cr^{++}; on irradiation, reduction to Cr^{+} was thought to occur. Schnerb and Bloch[6] found that potassium chloride crystals grown from aqueous solution containing added ferric chloride were opaque. Schulze[7] considered the dependence of the ratio of Sm^{++} to Sm^{+++} in potassium chloride, grown from a melt containing samarium chloride, on the pressure of chlorine over the melt.

Lidiard[8] showed that if the ionization potential associated with the removal of an electron from an atom or ion to yield a given oxidation state were greater than about 22 V., the element would not exist as a substitutional impurity in solid potassium chloride in the given oxidation state but in the lower one. Of elements having the stable + 3 state the third ionization potentials of which are known, only yttrium, lanthanum and cerium have potentials somewhat less than 22 V. The third ionization potentials of other rare earths are unknown: however, these elements, being similar to cerium, may dissolve in potassium chloride in the trivalent state. The boiling points of the lanthanon trihalides are all above 1,475°, so that evaporation from molten potassium chloride is negligible.

We have attempted to prepare single crystals of potassium chloride containing lanthanum, yttrium, gadolinium, dysprosium, samarium and neodymium; we have performed chemical analyses, examined the ionic conductivity, and studied the absorption spectra after additive and radiative coloration of a number of samples. Fifteen crystals were doped with gadolinium, four each with dysprosium and samarium, three each with lanthanum and yttrium, and one with neodymium.

Each of the anhydrous trihalides was prepared by drying the hydrate in a stream of dry hydrochloric acid mixed with nitrogen; the product was stored in a sealed vial and introduced into molten potassium chloride by breaking the vial under the surface of the melt. The composition of the melt was usually about 1 per cent in the added trihalide. Single crystals were grown by Czochralski's method. In the presence of air, the melt gradually became turbid due to formation of oxyhalide of the added element; some crystals were grown in an atmosphere of dry hydrochloric acid, which prevented this occurrence. The crystals frequently contained milky regions due to precipitation of the trihalide as a separate colloidal phase on cooling from the temperature of growth. Viewed along the axis of withdrawal of the seed-crystal, the white portion usually formed an X. The reason for this interesting observation is as yet unknown.

The crystals were analysed for rare earth elements (we include here yttrium and lanthanum) spectrophotometrically by means of the alizarin red *S* method due to Rhinehart[9]. Ionic conductivity was determined by means of a vacuum-tube volt-ohm-meter (supplied by the Precision Apparatus Co. Inc.), using platinum electrodes pressed against the faces of the sample crystal. Crystals were coloured additively by a method previously described[10]; a copper-target tube operated at 35 kV. was used for X-ray coloration.

The results of the chemical analysis clearly separated the crystal samples into two quite distinct categories. Those containing precipitated material as evidenced by a milky appearance contained from 0·90 to 133 × 10^{17}. rare earth ions/cm.^{3}. The former was doped with yttrium, the latter with gadolinium. Clear sections of crystal in no case contained more than 0·70 × 10^{17} cm.$^{-3}$, and in most cases the rare earth content was less than 0·50 × 10^{17} cm.$^{-3}$, the lower limit of detection. Dr. W. Hayes kindly examined clear sections of the gadolinium- and dysprosium-doped crystals using paramagnetic resonance, and reported no observable resonances attributable to trivalent ions. In the case of gadolinium, the sensitivity was such that 0·01 × 10^{17} trivalent ions/cm.^{3} would have been observed.

The ionic conductivity, and its temperature dependence, of the clear sections of all crystals was indistinguishable from that of crystals grown from recrystallized reagent-grade potassium chloride without added trihalide. Extrinsic conductivity of crystals containing colloidal precipitate was higher; calculations based on the data of Kelting and Witt, for a sample containing 28·5 × 10^{17} gadolinium ions/cm.^{3}, indicated that the conductivity at 370° corresponded to that due to 2 × 10^{17} trivalent ions/cm.^{3} or 4 × 10^{17} divalent ions/cm.^{3}. However, some of the additional conductivity may arise from irregularities in the crystal caused by the strain in the neighbourhood of the colloidal particles, and in view of the conductivity measurements on clear sections and the measurements of Hayes, we must conclude that the solubility of the trivalent cations at room temperature is below the limits of detection used here. The solubility of the rare earth elements in the divalent state may be somewhat greater, but in any event not greater than about 4 × 10^{17} ions/cm.^{3} at 370°. Experiments with radioactive tracers would be useful.

The absorption spectrum of additivity-coloured crystals doped with the trivalent metal halides exhibited no new bands resolvable by observation at 90° K. Crystals containing colloidal precipitate could not be coloured by treatment with potassium vapour. We presume that under the stringent reducing conditions, the rare earth element was reduced to metal; in fact, metallic specks were formed which were soluble in concentrated hydrochloric acid to give solutions yielding a strongly positive test for rare earth element with alizarin red *S*.

On the other hand, such crystals were coloured by X-irradiation. A broad band with a maximum at 325 mμ was observed in several crystals containing dysprosium and samarium in precipitated form. This band has not been obtained at room temperature in the case of undoped crystals, although Dorendorf[11] observed two small bands in this region in nominally pure potassium chloride irradiated with X-rays at −180°, which he designated V_6 and V_7. Either the rare earth impurity causes the band or enhances the stability of Dorendorf's bands at room temperature.

We conclude that the solubility of these trivalent cations is too small for them to exert any pronounced effects on the properties of potassium chloride crystals of ordinary purity. Their incorporation in potassium chloride of exceptional purity would probably be observable through their effect on extrinsic conductivity.

The assistance of F. Block and G. Robidart in obtaining and preparing the rare earth halides and that of Dr. W. Hayes, who measured the paramagnetic resonance absorption of several samples, is gratefully acknowledged.

Purification of Hydrogen Isotopes by Self-Displacement Chromatography at Low Temperatures

Gluekauf[1] has shown that protium and deuterium can be separated by displacement gas chromatography using columns of palladium black dispersed on asbestos. The most effective method was stated to be that of self-displacement, whereby the columns were initially charged at room temperature with a mixture of isotopes and then heated from the inlet end, progressively desorbing the gases. Because protium was more strongly adsorbed than deuterium, it functioned as the displacing gas in a displacement chromatography system, and the gases were desorbed as a band of deuterium followed by a band of protium. We have discovered that a similar method, using a column containing Molecular Sieve 5*A* initially at liquid-nitrogen temperature, results in an excellent separation of hydrogen isotopes with the difference that in this case the leading band consists of protium.

A column was prepared from two lengths of copper tubing each 10-ft. long by 3/16 in. bore, filling them with Molecular Sieve 5*A* of particle size 30–44 B.S.S. mesh and then activating the sieve by heating to 350° C. *in vacuo*. Each section was coiled into a helix of 4 in. diameter and they were joined together in series at a valve, which, with valves at the inlet and outlet ends, permitted isolation of both sections. The sections could be immersed separately in liquid nitrogen contained in Dewar flasks. Initially, the column was either evacuated, or filled with helium or deuterium at room temperature and isolated. It was then cooled and a measured volume of a hydrogen isotope mixture admitted to the first section of the column. The valve between the two sections was opened, and the column was slowly and progressively warmed from the inlet to the outlet end by successive lowering of the two Dewar flasks. The mixture absorbed at the inlet was thus caused to move along the column, and two bands of the pure isotopes developed. When the pressure inside the columns equalled atmospheric, the outlet of the second column was opened to a monitoring katharometer and the bands of displaced gases collected. The order of displacement was helium (if initially present), protium, a mixed fraction of both isotopes and finally pure deuterium. The trace obtained from the monitoring katharometer during the separation of a 10 per cent protium in deuterium mixture is shown

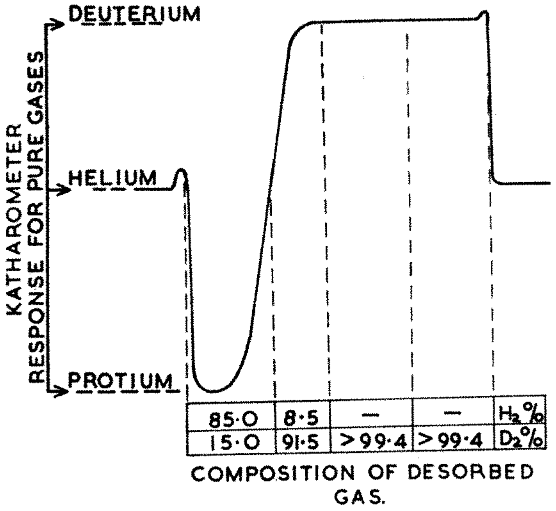

Fig. 1. Output of monitoring katharometer during self-displacement chromatography of a 10 per cent protium in deuterium mixture

in Fig. 1, the fractions collected being shown by the dotted lines. The fractions were analysed by gas elution chromatography[2].

If the original mixture is deficient in deuterium (the displacing gas) there may not be sufficient present to complete the displacement of the protium and in this case the purity of the deuterium band will not be as high. This was found to occur (Table 1), but even for a mixture containing only 25 per cent deuterium a considerable purification of deuterium was possible.

Table 1

Composition of original mixture	Fractions collected Composition H_2 (per cent)	D_2 (per cent)	Vol. (ml.)
90 per cent D_2, 10 per cent H_2	85	15	33·0
	8·5	91·5	40·2
	—	> 99·4	121
	—	> 99·4	101
25 per cent D_2, 75 per cent H_2	> 99·4	—	110
	99·4	0·6	79
	27·3	72·7	42
	10·6	89·4	50

The process is capable of operation on a larger scale and charges of 2·5 litres in volume have been processed using a first section of copper tubing 15 in. in length by 3/4 in. bore, packed with 1/16 in. pellets of Molecular Sieve 5*A* and the second of the same dimensions as used previously. The second section was effective as a front sharpener as well as contributing to band formation, by reducing the diffusion effects inherent in wider bore columns and hence the volume of the mixed band between the two fractions. Results with the larger columns were comparable to those with the small columns. For example, from 2·0 litres of mixture containing 8 per cent protium, 1·7 litres of deuterium containing 1 per cent or less of protium were obtained in a single run over a period of 1 hr.

The adsorptive capacity of the Sieve is 43·5 ml. of protium/gm. and 47·5 ml. of deuterium/gm. With such relatively high capacities, a laboratory-scale apparatus may readily be constructed which is capable of purifying several litres of hydrogen isotope mixture per hour. The process can be made repetitive, for after the first run the column requires no further preparation, the deuterium remaining being readsorbed on to the first section by cooling before the next charge is admitted.

With the limitation that the columns had to be filled initially with helium at atmospheric pressure, columns containing alumina impregnated with ferric oxide were found to operate in a similar manner, but their adsorptive capacity was less. Self-displacement chromatography using columns of pure alumina would appear to offer a method of separation of quantities of the spin isomers of either protium or deuterium as it has been shown they may be separated by elution chromatography on such a column[3].

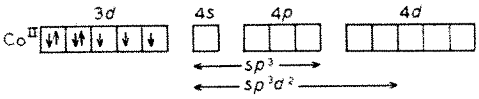
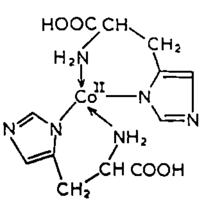
Structure of the Oxygen-carrying Cobalt (II) Histidine Complex

Bis-histidinato cobalt (II) is one of the few synthetic compounds which can combine reversibly with molecular oxygen. Hearon *et al.*[1] obtained a value of 4·44 Bohr magnetons (B.M.) for its effective magnetic moment at room temperature in aqueous solution, and showed that on oxygenation it became almost diamagnetic with the absorption of one oxygen molecule for two cobalt atoms. For three unpaired electrons the spin-only moment would be 3·88 B.M., and the considerably larger experimental value obtained in this case was ascribed to incomplete quenching of the orbital contribution to the moment. From the magnetic measurements Hearon assigned a tetrahedral structure (*sp*³ hybridization), I, to the complex:

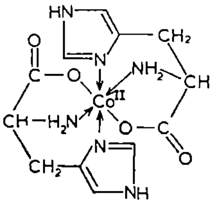


in which the cobalt atom was co-ordinated to the α-amino group and an imidazole nitrogen atom of each histidine molecule. However, histidine can behave as a tridentate ligand, and an octahedral configuration, II, involving co-ordination of ionized carboxyl groups is not unlikely. Hearon considered this to be only a secondary possibility.

Because of the differing orbital contributions, tetrahedral and octahedral cobalt (II) complexes generally have effective magnetic moments at room temperature in the ranges 4·3–4·7 and 4·8–5·6 B.M. respectively[2]. This would appear to confirm the tetrahedral structure of the complex, but Hearon has reported its aqueous solution to be pink, typical of octahedral rather than the commonly blue tetrahedral complexes.



(I)



(II)

We have prepared solid *bis*-histidinato cobalt (II) in oxygen-free conditions, using an apparatus already described[3], by concentrating the solution obtained by dissolving cobalt (II) hydroxide in an aqueous solution of histidine—the method used by Jaselskis[4] Our analyses agree with his formulation of the compound as the monohydrate The solid is pink with an effective moment of 4 81 B M at 291° K , it obeys the Curie–Weiss law between 80 and 300° K , and $\theta = 17°$, these values are comparable with those obtained for other spin-free, octahedral cobalt (II) complexes by Figgis and Nyholm[2b] The variation with temperature of molar susceptibility χ_M and effective moment μ_{eff} is shown in Table 1

Table 1

$T°$ K	86 2	116 3	147 8	176 2	204 7	232 1
$\chi_M \times 10^6$	29,750	22,850	18,630	15,900	13,890	12,320
μ_{eff}	4 55	4 63	4 71	4 75	4 79	4 80
$T°$ K	261 5	291 0	305 3	322 2		
$\chi_M \times 10^6$	10,910	9,833	9,453	8,956		
μ_{eff}	4 80	4 81	4 82	4 83		

The magnetic moment of the compound re-dissolved in water was 5 16 B M at 297 2° K , much higher than that recorded by Hearon The measurements were repeated on a solution of the complex prepared by mixing aqueous solutions of histidine and a cobalt salt, and a value of 5 13 B M was obtained This method was used by Hearon, but he allowed momentary exposure to the atmosphere during the filling of the susceptibility tube There is some inconsistency in the concentrations recorded by Hearon for his solutions and we believe that either crystallization or partial oxidation of the compound may account for the low moment obtained Our values of moment from the solution measurements are well within the range expected for octahedral spin-free cobalt (II) complexes, and agree with the value of 4 97 B M reported by Michaelis[5] for the complex in solution

The visible absorption spectrum of the complex in aqueous solution[1] is very similar to the spectra of octahedrally co-ordinated cobalt (II) complexes[6] and shows a weak band at 486 mμ ($\varepsilon = 18\ 4$) The reflectance spectrum of the solid has a peak at the same wave-length

In the infra-red spectrum of the cobalt histidine complex obtained in a 'Nujol' mull a broad, intense band appears at 1,587 cm $^{-1}$, which is unchanged on deuteration Since it is well below the 1,700 cm $^{-1}$ region where non-ionized carboxyl groups absorb[7], it must arise from the asymmetrical stretching vibration of ionized and probably co-ordinated carboxyl groups Consequently, structure I, which necessitates unco-ordinated non-ionized carboxyl groups, cannot be correct

These measurements show that the cobalt atom is in an octahedral environment and are in agreement with the recent work of Leberman and Rabin[8], who have deduced from potentiometric titration data that all three available donor groups of the histidine molecules are co-ordinated to the metal atom in complexes with cobalt (II), nickel (II), zinc (II), and probably cadmium (II)

Some Tetrahydropyranyl Derivatives of Glycine, Serine and Urea

THE provision of model compounds containing amino-acids or their analogues attached to sugars is of importance in evaluating the stability of the numerous types of carbohydrate-peptide linkages theoretically possible in mucoproteins. The ability of 2,3-dihydropyran to condense with $-OH$, $-SH$, and $-NH_2$ groupings suggested a route to the glycosidically linked model compounds The tetrahydropyran-2-yl derivatives so formed had the added advantage that the lability of the glycosidic linkage could be investigated without attendant complications such as acyl migration under alkaline conditions or Amadori re-arrangement catalysed by acid which might ensue in the presence of a hydroxyl substituent at C–2 of the pyran ring

In the condensation between 2,3-dihydropyran and *N*-benzylsulphonyl-serine (DL-mixture) the tetrahydropyran-2-yl residue was introduced solely at the hydroxymethyl grouping, no evidence for reaction with the acidic hydroxyl was detected *N*-Benzylsulphonyl-serine (9 7 gm) in ether-ethyl acetate (1 1 v/v) was stirred at ambient temperature for 15 days with 2,3-dihydropyran (9 7 gm) in the presence of two drops of concentrated hydrochloric acid After neutralization (silver carbonate), the solution was evaporated and the residue extracted successively with water and ethyl acetate The latter extract yielded crystalline *O*-tetrahydropyran-2-yl-*N*-benzylsulphonyl-serine (10 4 gm), m p 130–132°, after five recrystallizations from ethyl acetate The optically inactive product contained C, 52 5, H, 5 8, S, 9 55 per cent and had an equivalent weight of 349 by titration, $C_{15}H_{21}NSO_6$ requires C, 52 4, H, 6 1, S, 9 3 per cent and an equivalent weight of 343 Addition of aqueous 0 5 *N* silver nitrate to a cooled (0°) methanolic solution of the serine compound precipitated the crystalline silver salt Found C, 40 8, H, 4 5, N, 3 1, Ag, 23 4 per cent, $C_{15}H_{20}O_6$-NSAg requires C, 40 0, H, 4 5, N, 3 1, Ag, 23 95 per cent Under similar conditions *S*-tetrahydropyran-2-yl-L-cysteine yields the silver mercaptide of cysteine[1]

Preparation of the *N*-glycoside adducts was rendered difficult by their instability An aqueous solution of glycine (10 gm), tetrahydropyran-2-ol (5-hydroxypentanal) (13 4 gm) and sodium bicarbonate (12 gm) was stirred at room temperature for 90 hr The residue obtained on evaporation (below

40° C.) was kept in a vacuum desiccator over phosphorus pentoxide for 3 days and further dried for 1 hr. at 63° C. Thereafter, the residue (4·7 gm.) was extracted with dry methanol and the crude sodium salt of *N*-tetrahydropyran-2-yl glycine precipitated with ether. After six such treatments a relatively pure but unstable amorphous product was obtained giving a positive Erhlich reaction[2] (without acetylacetone). On paper chromatograms irrigated with butan-1-ol/ethanol/water (4 : 1 : 5) it decomposed into a mixture of tetrahydropyran-2-ol (detected with a 2,4-dinitrophenylhydrazine spray[3]) and sodium glycinate (revealed by ninhydrin[4]). The corresponding ethyl and benzyl esters of *N*-tetrahydropyran-2-yl glycine were more stable and moved as chromatographically homogeneous components with R_F 0·89 and 0·90 respectively (cf. glycine ethyl ester R_F 0·4) as revealed by chlorine–potassium iodide treatment[5]. Kaverzneva and Kalis[6] have shown that the sodium salt of *N*-D-glucosylglycine is readily hydrolysed in aqueous solution at room temperature. Other workers[7] have demonstrated that *N*-D-glucosylglycine ethyl ester undergoes slow hydrolysis in aqueous solution at room temperature and is rapidly and quantitatively hydrolysed at 90° C. The pyranyl derivatives were prepared by reaction of the appropriate ester and dihydropyran for 17–20 days at room temperature in dimethylformamide (ethyl ester) or ether (benzyl ester, anhydrous magnesium sulphate added) containing a trace of mineral acid. A mixture of dihydropyran (2·1 ml.) and urea (0·6 gm.) in dimethylformamide (30 ml.) containing a trace of concentrated hydrochloric acid gave, after 96 hr. at 17° C., two products with R_F 0·70 and 0·93 (butan-1-ol–ethanol–water). The mixture was taken up in water (30 ml.), extracted with chloroform (6 × 50 ml.) which was back-washed with water (2 × 50 ml.). The dried chloroform solution contained the more mobile component which, after re-crystallization from acetone (twice), chloroform (twice) and ethanol (six times), yielded pure *NN'*-di-tetrahydropyran-2-yl-urea, m.p. 211–212° C., dropping to 201–202° C. after standing for 24 hr. The freshly isolated compound contained C, 57·9, H, 8·5, N, 12·3 per cent, $C_{11}H_{20}O_3N_2$ requires C, 57·9, H, 8·8, N, 12·3 per cent. The aqueous layer obtained after chloroform extraction of another urea-dihydropyran condensation was freeze-dried and separated on a cellulose column eluted with butan-1-ol/ethanol/water (4 : 1 : 5). The *N*-tetrahydropyran-2-yl-urea fraction (R_F 0·70) so obtained was repeatedly recrystallized from chloroform and ethanol to yield the pure compound, m.p. 187–188° C. (melting at 178–179° after 24 hr.). Found: C, 50·0; H, 8·3, N, 19·4 per cent, $C_6H_{12}O_2N_2$ requires C, 50·0, H, 8·3, N, 19·4 per cent. Hydrolysis of both pyranyl ethers at 100° with 'Zeo-Karb 225' (H^+) afforded urea and tetrahydro-pyran-2-ol (characterized as its 2,4-dinitrophenylhydrazone, m.p. 107–109° C.[8]). Benn and Jones[9] have characterized the products of the acid-catalysed condensation of D-glucose and urea as *N*-β-D-glucopyranosyl- and *NN'*-di-β-D-glucopyranosyl-urea.

The relative stability of the tetrahydropyranyl derivatives was determined by hydrolysis of an aliquot (8–10 mgm.) in 1 ml. of aqueous acid or alkali, neutralization and estimation of the tetrahydropyran-2-ol liberated using alkaline hypoiodite[10]. Control experiments showed that the original compound was stable under the conditions used in estimation. *N*-Tetrahydropyran-2-yl-urea was more stable under alkaline conditions [0·1 *N* sodium hydroxide for 15 min., percentage hydrolysis 30 (80° C.), 57 (100° C.)] than acid conditions [0·01 *N* hydrochloric acid for 15 min., percentage hydrolysis 11 (40° C.), 67 (60° C.), 87 (80° C.), 100 (100° C.)]. A similar stability was exhibited by *NN'*-di-tetrahydropyran-2-yl-urea [0·01 *N* hydrochloric acid for 15 min., percentage hydrolysis, 97 (100° C.). 0·1 *N* sodium hydroxide for 15 min., percentage hydrolysis, 61·5 (100° C.)]. *N*-Tetrahydropyran-2-yl-glycine decomposed in water within a few minutes, but was stable in ethereal suspension at room temperature. The stability of *O*-tetrahydropyran-2-yl-*N*-benzylsulphonylserine was not much different under corresponding acid [0·01 *N* hydrochloric acid for 15 min., percentage hydrolysis, 25 (40° C.), 71 (60° C.), 92 (80° C.), 100 (100° C.)] and alkaline conditions [0·01 *N* sodium hydroxide for 15 min., percentage hydrolysis, 37 (50° C.), 67 (60° C.), 100 (100° C.)].

Carcinogenicity of the Methyl-1,2-Benzanthracenes and their Derivatives

A number of theories have recently been put forward to account for the carcinogenic activity of the polycyclic aromatic hydrocarbons, in their present form, the majority of these theories do not provide a rationale for the fact that a number of chemically dissimilar carcinogens appear to operate through some common protein deletion principle[1]. Previous descriptions of a possible mechanism of carcinogenesis[2-4] have pointed out, however, that, in principle at least, the unifying mechanism by which such carcinogens act may be their formation of charge-transfer complexes with proteins, we are now able to discuss the activities of the methyl-1,2-benzanthracenes and the mono-fluoro-10-methyl-1,2-benzanthracenes (Fig. 1) in such terms.

The calculation of the electron distribution in these molecules has been performed within the framework of the usual linear combination of atomic orbitals–molecular orbital (L.C.A.O.–M.O.) method, where we describe the molecule by specifying which molecular orbitals are allowed for the π electrons and what are their energies. The orbital energies are given in the form

$$E_i = \alpha + k_{ij}\gamma$$

α and γ being the usual Coulomb and resonance integrals of the Wheland approximation The difference in energy between two levels i and j is quite simply

$$\Delta E_{ij} = (k_i - k_j)\gamma$$

and is therefore independent of α The values of the coefficients $(k_i - k_j)$ are listed in Table 1

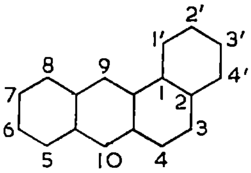

Fig 1 Numbering of the ring positions in 1,2-benzanthracene

In the case of the aromatic hydrocarbons, the criterion for activity was established[2,3] as

$$\Delta E_{1,\bar{2}} \approx 3\ 24 \pm 0\ 12\ \mathrm{eV}$$

This energetic criterion was taken as implying that for a π complex to describe the transition state of the hydrocarbon–protein interaction, matching of energy levels in the complex was necessary, the highest filled orbital of the hydrocarbon coincided with the lowest filled band of the protein while the second unfilled level acted as a resonating level for conversion of electrons from the valence band to the lowest unfilled level of the carcinogen An inspection of Table 1 now shows that the active range for the methyl-1,2-benzanthracenes and the fluoro-10-methyl-1,2-benzanthracenes is

$$1\ 3341\gamma < \Delta E_{1,\bar{3}} < 1\ 4462\,\gamma$$

There are two exceptions only in the case of the methyl benzanthracenes to activity as defined by this criterion both 5,8-dimethyl and 2′6-dimethyl 1,2-benzanthracene are allowed to be active whereas they are in fact inactive The experimental data for the mono-fluoro derivatives are less complete, their most interesting feature is the dependence of the activity on fluoro-substitution in the '*K*' region, for the 4 isomer is strongly carcinogenic while the 3 derivative is inactive[5,6] This is now consistent with theory which shows 3-fluoro-10-methyl-1,2-benzanthracene to fall well outside the active range with $\Delta E_{1,\bar{3}} = 1\ 2824\,\gamma$ For those molecules which remain to be tested theory predicts

(i) the 1′- and 2′-fluoro-10-methyl-1,2-benzanthracenes should be active, (ii) both the 5 and 8 isomers fall just a little outside our present 'active' range with $\Delta E_{1,\bar{3}}$'s of 1 3286 and 1 3327 respectively, since we have no molecules the activities of which are known with such low values of $\Delta E_{1,\bar{3}}$ we cannot be certain as to the probable activities of these compounds, and (iii) the 9-fluoro isomer has $\Delta E_{1,\bar{4}}$ lying within the active range There seems no reason why the fourth unfilled level should not be used as the resonating charge transfer-level so that we would predict this molecule to be active Evidence of inactivity would indicate that a common resonating level must be used by all the molecules of an isomeric series and would clearly be of considerable interest

Note For the methyl group, $>C_2-C_1\equiv H_3$, the following parameters have been used

$$\alpha_{C_2} = \alpha_C - 0\ 1\beta$$
$$\alpha_{C_1} = \alpha_C$$
$$\alpha_{H_3} = \alpha_C - 0\ 5\beta$$
$$\beta_{C_1\equiv H_3} = 2\ 5\beta_{C=C}$$
$$\beta_{C_1-C_2} = 0\ 7\beta_{C=C}$$

For the fluorine atom

$$\alpha_F = \alpha_C + 1\ 0\beta$$
$$\beta_{C-F} = \beta_{C=C}$$

The interpretation of the activities of the methyl benzanthracenes has always been one of the most demanding requirements of any electronic theory of the mechanism of carcinogenesis The success of the π complex model in this sense together with its explanation of the differences in activity between the 3- and 4-fluoro-10-methyl-1,2-benzanthracenes must be regarded as some further justification for its acceptance On the other hand, the original difficulties of the model remain The calculated energy-levels are based on an approximation which ignores the singlet-triplet separation of states arising through π electron excitation, moreover, this separation is not constant for all the carcinogenic alternant hydrocarbons although it is likely that it will be similar for the molecules discussed here There is also the problem of the effects of mutual polarization on the energy-levels of the protein and hydrocarbon and its bearing on the likelihood, or otherwise, of the presence of resonating levels in the π complex The attractiveness of the model undoubtedly lies in its simplicity and its ability to predict critical experiments Davis *et al* [7] have measured the enhanced semiconductivity of protein complexes and interpreted the results in a way consistent with the mechanism put forward here Spectroscopical investigations of the hydrocarbon-protein complexes formed *in vivo* would clearly be also useful in defining the nature of the interaction From the theoretical point of view, we hope to be able to examine the problem more realistically by the use of more sophisticated models for the carcinogens and protein since the present approach does not offer convincing evidence that the charge-transfer hypothesis is a unique, rather than the most economical, description of the carcinogenic interaction

BIOCHEMISTRY

Hydrolysis of Hippuric Acid in Electrolytic Desalters

IN 1947 Consden, Gordon and Martin[1] published the design of an apparatus for the removal of salts from solutions of amino-acids and peptides by electrolysis Since that time this method has been frequently used for the preparation of samples for the analysis of urinary amino-acids by paper chromatography Whenever this has been done little account seems to have been taken of the fact that hippuric acid, which is present in relatively large quantities in some urines, is a fairly strong organic acid, and for that reason approaches the semipermeable membrane of the desalter at an early stage in the electrolysis, and is there hydrolysed to benzoic acid and glycine The purpose of this communication is to show that glycine released by the hydrolysis of hippuric acid is retained in the cathode compartment of the desalter, where it adds to the amount of free glycine already present in the urine, and that the increase in free glycine is dependent on the initial concentration of hippuric acid and salt.

In the course of work on the determination of amino-acids in urine using electrolytic desalting followed by paper chromatography[2-4], it was found that the mean 24-hr excretion of glycine from ten subjects of European stock was 3 43 m moles/24 hr , whereas the mean value obtained by Stein[5] using an ion exchange procedure was 1 76 m moles/24 hr , and that obtained by Gutman and Alexander[6] using a chemical method was 1 60 m moles/24 hr The fact that some microbiological methods were giving values in the region of 10 m moles/24 hr [7], and that these high values were attributed to a greater activity of the micro-organism concerned for hippuric acid, led to the possibility that the high results obtained in my experiments could have been due to the retention of glycine in the cathode compartment subsequent to the hydrolysis of hippuric acid at the semipermeable membrane

All the results quoted here were obtained with a small 'Perspex' electrolytic desalter using the same basic principle as that of Consden, Gordon and Martin[1], but designed for the rapid desalting of solution volumes not greater than 1 ml In each case a starting current of 0 9 amp and a voltage rising to about 200 V was applied to the electrolysing solution. The fact that the hydrolysis of hippuric acid and the factors affecting it are not peculiar to a particular design of electrolytic desalter was shown when similar results were obtained from the electrolytic desalter of Astrup, Stage and Olsen[8]

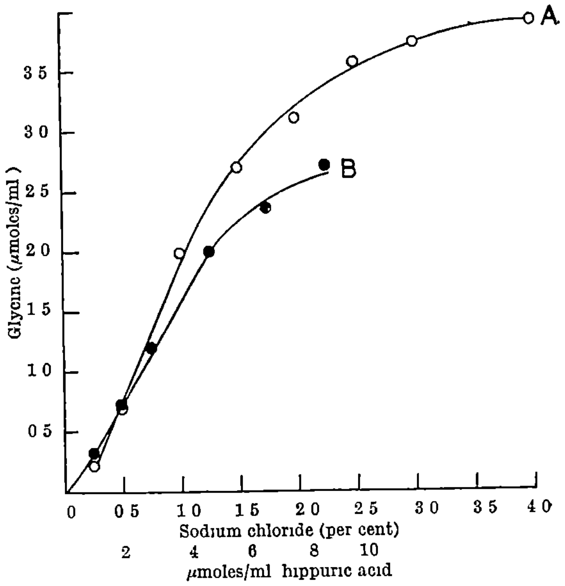

Fig 1 *A* shows the amount of glycine retained in the cathode compartment when the initial concentration of sodium chloride is varied and the initial concentration of hippuric acid is constant at 5 0 μmoles/ml *B* shows the amount of glycine retained in the cathode compartment when the initial concentration of hippuric acid is varied and the initial concentration of sodium chloride is constant at 1 0 per cent

The initial possibility that hippuric acid hydrolysis took place and resulted in the retention of free glycine in the cathode compartment of the desalter was examined by desalting a solution of hippuric acid in 1 2 per cent sodium chloride A sample of the desalted solution was chromatographed and glycine was found to be present A control was carried out by electrolysing a pure solution of hippuric acid for the same length of time, and this produced no free glycine Desalting a solution of glycylalanine in 1 2 per cent sodium chloride produced no free glycine, which would seem to indicate that neutral peptides are unaffected

A series of experiments was then carried out to determine the effect of changing concentrations of salt on the rate of hydrolysis of constant amounts of hippuric acid, and, also, the effect of changing amounts of hippuric acid in solutions in which the initial concentration of sodium chloride was kept constant The results of these experiments are shown in Fig 1 Each electrolysis was carried out by placing 1 ml of the test solution in the desalter No loss of glycine occurs during electrolysis in this desalter[9] The desalting time varied from 2 to 15 min depending on the initial concentration of sodium chloride

Curve *A* shows that the amount of free glycine retained in the cathode compartment approaches an equilibrium between 3 and 4 per cent sodium chloride for a constant amount of hippuric acid Curve *B* also shows a tendency to approach an equilibrium, and it is clear that the position of this equilibrium will be determined by the initial concentration of salt Unfortunately, it was not possible to extend curve *B* any further due to an uncontrollable amount of heat being evolved at higher concentrations of hippuric acid

All efforts to prevent the hydrolysis of the hippuric acid either by varying the starting current and voltage or the concentration of the sulphuric acid flowing through the anode compartment resulted in failure

No attempt has been made to examine experimentally the possible mechanisms involved in the retention of glycine in the cathode compartment, or of the hydrolysis of the hippuric acid at the semipermeable membrane It seems reasonable to suggest, however, that the basic factor involved is the very low *p*H which, according to Consden, Gordon and Martin[1], prevails in the region of the semipermeable membrane At the commencement of electrolysis the amount of chloride ion passing through the semipermeable membrane should be dependent on the initial concentration of sodium chloride This movement of chloride ions from the cathode towards the membrane is presumably balanced by a similar movement of hydrogen ions supplied by the sulphuric acid on the anode side of the membrane The concentration of hydrogen ions available in the region of the membrane would thus be determined by the amount of chloride ion approaching the membrane and would in turn determine the rate of hydrolysis of the hippuric acid together with the degree of retention of glycine in the cathode compartment

These results show that great care must be taken when examining paper chromatograms of urinary amino-acids after electrolytic desalting, since the amount of free glycine found on the chromatogram will be seriously affected to a varying degree depending on the initial concentration of hippuric acid and salt in the urine In general, electrolytic desalting should be avoided in any work involving the quantitative determination of glycine in urine

Purification of Fluorescent Protein Conjugates : Comparison of Charcoal and 'Sephadex'

REMOVAL of unreacted fluorescent material from fluorescent protein conjugates is essential for unambiguous interpretation of microscopical findings in immunofluorescence[1] Many procedures have been suggested for conjugate purification, but extraction with powdered activated charcoal[2] and gel filtration with 'Sephadex'[3,4] are at present the only efficient methods suitable for general application These two methods have been compared as purification procedures for conjugates of lissamine rhodamine *B* (*RB* 200) and fluorescein isothiocyanate We have confirmed the inefficiency of dialysis[5] after exhaustive dialysis (7–10 days), conjugates still contain appreciable unreacted fluorescent material which can be removed by shaking with charcoal or passage through 'Sephadex'

The powdered activated charcoal supplied by British Drug Houses, Ltd, for general decolorizing purposes has been found to be the most efficient material for removal of unreacted fluorescent material It may contain soluble substances which affect the *p*H of the solution, but after thorough washing in phosphate-saline (0 15 *M* sodium chloride, 0 01 *M* phosphate, *p*H 7 1) and water, and drying at 100° C, it remains highly adsorbent The effect of shaking different amounts of charcoal for 1 hr with samples of the same conjugate has been examined by measuring the ratio of dye to protein concentrations This ratio decreases to a constant value for both *RB* 200 and fluorescein isothiocyanate conjugates, as the amount of charcoal is increased (Table 1) For *RB* 200 conjugates, 15 mgm charcoal per ml of original serum is sufficient to reduce the ratio to its lowest value, but for fluorescein isothiocyanate conjugates, at least 75 mgm per ml is required, double these quantities are normally used to allow for small variations in conjugates Only 5–10 per cent protein is lost from *RB* 200 conjugates, but the larger amount of charcoal for fluorescein isothiocyanate conjugates removes 30–40 per cent protein

Table 1 RATIO OF DYE TO PROTEIN IN CONJUGATES EXTRACTED WITH CHARCOAL (µGM /MGM)

Mgm charcoal per ml original serum	0	15	30	75	150	300
RB 200 conjugate	36	16	17	17	17	—
Fluorescein isothiocyanate conjugate	33	—	27	23	22	22

Purification by gel filtration is achieved by passing the centrifuged conjugate through a column of 'Sephadex *G*–25', which has been washed with phosphate-saline The protein conjugate is eluted by phosphate-saline and travels more rapidly than the unreacted fluorescent material A clear region develops between two coloured bands and the purified conjugate is collected first, there is very little loss of protein The elution is continued to remove unreacted fluorescent material and clean the column for further use Dilution of the conjugate (about three-fold) is of little consequence since the globulin fraction may be precipitated and reconstituted

The antibody content of conjugated rabbit serum (anti-bovine-serum-albumin) has been measured by precipitation before and after purification by charcoal and by Sephadex' The percentage recovery of antibody has been the same as the total yield of protein in each case, indicating that antibody is neither selectively removed from the conjugate nor denatured *RB* 200 and fluorescein isothiocyanate conjugates of rabbit serum (anti-klebsiella) and goat serum (anti-rabbit-globulin), purified by each technique and brought to equal protein concentration, were examined for specific and non-specific staining and compared with dialysed samples Both direct and sandwich staining were tested with a large series of histological and bacteriological preparations No significant differences were found between charcoal- and 'Sephadex'-purified conjugates, both gave substantially less non-specific staining than the dialysed conjugates

The convenience of a simple batch process recommends powdered activated charcoal as the most suitable routine purifying agent, it has always given uniformly satisfactory results with *RB* 200 conjugates Our original experience with fluorescein conjugates was less satisfactory[5], but since using pure fluorescein isothiocyanate for conjugation and adopting the present standard procedure of charcoal extraction, consistently good results have been obtained The 'Sephadex' method, although time-consuming and less simple, is as efficient as charcoal extraction and may be preferred for fluorescein isothiocyanate conjugates of any weak sera which cannot be handled by sandwich staining

We thank Dr G S Warner for gifts of pure fluorescein isothiocyanate, and Prof W O Kermack and Dr M G McEntegart for helpful advice The research programme has been supported by a grant from the Scottish Hospital Endowments Research Trust

Gas Chromatography of Androst-16-en-3α-ol and Related Steroids

DURING the course of work on the *in vitro* biosynthesis of androst-16-en-3α-ol (androstenol, I) from 2-^{14}C-acetate or ^{3}H-acetate by rabbit and guinea pig testes[1], it was found that the highly radioactive saponifiable lipids present could be only partially separated from the slightly active I on alumina, using as eluant light petroleum/benzene (1 1, v/v) Although in later experiments the neutral lipids were removed by saponification before column chromatography, it was considered that the technique of gas chromatography might provide an alternative method of separating (I) in view of recent results obtained in the steroid field[2-5]

We have used as stationary phase a non-polar silicone gum, *MS* 2211 (Midland Silicones, Ltd.) This was dissolved in toluene and stirred with sufficient acid-washed 'Celite 545' (85–100 or 100–120 mesh) to give 0 5, 1 5, 10 and 15 per cent (w/w) as already described[1] Fig 1 shows the separation of (I)[6] from a mixture of fatty acids up to C_{18}, using 15 per cent silicone gum on 'Celite 545'. With this relatively high concentration of stationary phase a fairly good separation was obtained but the retentions of columns having only 0 5 or 1·5 per cent were too small to allow adequate separation Although such columns could well be of use in the analysis of bile acids (cf. VandenHeuvel, Sweeley and Horning[7]), they were not investigated further in relation to (I)

Using this 15 per cent column, an attempt has also been made to separate androstenol from a group of four steroids, similar to it both chemically and in their mobility on fully acetylated paper[1] These compounds, all generously supplied by Dr C L Hewett (Organon Laboratories, Ltd), were the 3β-epimer of I (androst-16-en-3β-ol, II), ætiochol-16-en-3α-ol (III), androst-5 16-dien-3β-ol (IV), and œstra-1 3 5 16-tetraen-3-ol (V) They were each applied to the column as 10 per cent (w/v) solutions in distilled methyl laurate, which contained enough myristic ester to serve as a reference substance Analyses were carried out at six temperatures within the range 145–225°, using appropriate argon flow-rates and suitable chart-speeds in the recording potentiometer[8] The results, together with the retention of each steroid relative to myristic ester and the calculated number of theoretical plates, are shown in Table 1.

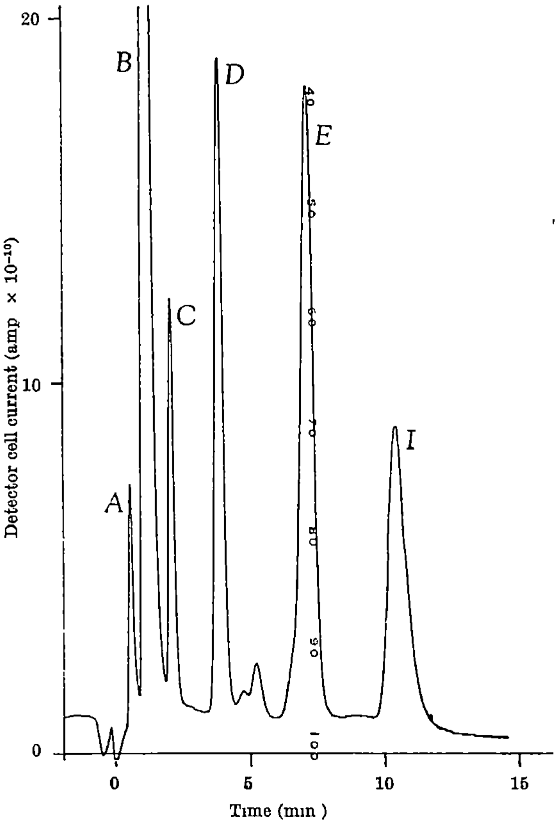

Fig 1. Vapour phase chromatogram of 10 μgm. androsten-3α-ol (I), showing separation from methyl esters of (*A*) capric, (*B*) lauric, (*C*) myristic, (*D*) palmitic and (*E*) stearic acids Stationary phase, 15 per cent silicone gum *MS*2211 on 'Celite', at 206° C , argon flow-rate 35 ml /min

Compounds III and V could be resolved from each other and from I, II and IV without difficulty, but the latter group of three steroids showed very similar properties and only partial resolution was achieved Separation did not alter significantly over this range of temperature. Evidence of the thermal instability of I, II and IV was noticed at 185°, increasing markedly as the column was run at higher temperatures Below 185°, however, the substances appeared stable even though they were retained for considerable periods

After plotting the reciprocal of the absolute temperature against $\log_{10}$ (relative retention), it was clear that effective resolution of I, II and IV from one another would be possible with silicone gum as stationary phase in the range 150–180°, provided that columns equivalent to 45,000 theoretical plates were used This should be possible with capillary

Table 1 RETENTIONS RELATIVE TO METYHL MYRISTATE OF SOME STEROIDS AT DIFFERENT TEMPERATURES ON A SILICONE GUM COLUMN

Effect of Insulin on Pathways of Glucose Oxidation in the Rat Lens

EXPERIMENTAL evidence as to whether lens is a tissue which responds to insulin has been inconclusive. Some investigators have found that glucose uptake by the isolated intact lens is increased after administration of insulin *in vivo*[1,2] However, neither a direct effect *in vitro* on glucose uptake could be demonstrated[1,3], nor did insulin influence the accumulation of labelled glucose by the intact lens[4] Recent work in this laboratory has shown that insulin causes a small but consistent increase of glucose uptake by the intact lens in Krebs–Ringer bicarbonate medium[5] Kinoshita and Wachtl[6] have found that lens is capable of metabolizing glucose by both the Embden–Meyerhof pathway and the hexose monophosphate shunt This communication deals with the effect of insulin on the two oxidative pathways in the rat lens and demonstrates an alteration of glucose oxidation in lenses of diabetic rats

Lenses of rats of body-weight 100–105 gm were excised as described in ref 5 Diabetes was produced by intraperitoneal injection of 14 5 mgm of alloxan/100 gm. body-weight; those animals having blood glucose-levels, when fed, of at least 350 mgm. per cent after three weeks were considered to be diabetic Glucose-1-^{14}C and glucose-6-^{14}C were obtained from the Radiochemical Centre, Amersham, England. Carbon-14 labelled carbon dioxide produced during incubation was collected and counted as barium carbonate on a windowless gas-flow counter, corrections to infinite thinness were made according to an experimentally determined self-absorption curve Results were calculated according to the following formula

$$\mu\text{moles of added glucose converted to } ^{14}\text{CO}_2 = \frac{\text{c.p m as barium carbonate}}{\text{specific activity of medium glucose}} \times 10^3$$

Values were multiplied by 10^3 in order to present the results as whole numbers since the absolute amount of conversion was low

The stimulatory effect of insulin on the oxidation of glucose-1-^{14}C to carbon-14 labelled carbon dioxide may be seen in Table 1 This activation of the hexose monophosphate shunt by insulin was small (about 20 per cent) but significant ($P < 0\ 01$) and was consistently observed in all experiments At the same time it may be seen that the oxidation of glucose-6-^{14}C to carbon-14 labelled carbon dioxide was depressed in the presence of insulin by about 50 per cent This finding, although unexpected, has also been noted in experiments with mammary glands[7]

Table 1 EFFECT OF INSULIN ON THE OXIDATION OF GLUCOSE-1-^{14}C AND GLUCOSE-6-^{14}C TO $^{14}CO_2$ IN RAT LENSES

	Insulin	No of exp	μmoles of glucose converted to $^{14}CO_2$ × 10^{-3}	Insulin effect (per cent)
Glucose-1-^{14}C	–	6	12 39 ± 0 43	
	+	6	15 01 ± 0 48	+ 21
Glucose-6-^{14}C	–	4	0 55 ± 0 04	
	+	4	0 29 ± 0 04	– 46

Incubation medium 1 2 ml of Krebs–Ringer bicarbonate buffer *p*H 7 4, containing 5 8–6 5 μmoles non-labelled glucose plus labelled glucose to give specific activities of 147,000–176,000 c p m /μmole glucose Insulin, when added, was 0 1 unit/ml Incubated at 37° for 2 hr in 95 per cent oxygen–5 per cent carbon dioxide Each Warburg vessel contained three lenses (average weight, 25 2 mgm) from rats fasted for 16 hr Potassium hydroxide was injected through a special rubber stopper at the end of incubation, and after addition of sulphuric acid from side-arm the carbon dioxide released was collected for 45 min

When these experiments were performed in a medium of Krebs–Ringer phosphate instead of bicarbonate, no insulin effect could be observed in either of the oxidative pathways

Investigations on lenses from diabetic rats (Table 2) indicated that the production of carbon-14 labelled carbon dioxide from glucose was depressed in the diabetic state by about 20 per cent The extent to which the oxidation of this sugar via the hexose monophosphate shunt was diminished in diabetes was of the same order of magnitude as the amount of activation observed when insulin was added *in vitro* to normal lenses No consistent alteration in carbon-14 labelled carbon dioxide production from glucose-6-^{14}C could be demonstrated in lenses from diabetic rats

Table 2 OXIDATION OF GLUCOSE-1-^{14}C AND GLUCOSE-6-^{14}C BY LENSES OF DIABETIC RATS

	Lenses used	No of exp	μmoles of glucose converted to $^{14}CO_2$ × 10^{-3}	Percentage of change in diabetes
Glucose-1-^{14}C	Normal	4	13 82 ± 0 78	
	Diabetic	4	10 84 ± 0 09	– 22
Glucose-6-^{14}C	Normal	6	0 40 ± 0 04	
	Diabetic	4	0 37 ± 0 06	none

Incubation medium and conditions the same as in Table 1, except rats were fasted for two days

The stimulatory effect of insulin on the hexose monophosphate shunt found in these experiments does not necessarily indicate that insulin is acting directly on the enzyme systems of this oxidative pathway. One of the present theories of insulin action is that it mediates in the transport of glucose into the cell It is possible that insulin might, in this case, facilitate the transfer of glucose to that site in the lens where the hexose monophosphate shunt is operating

Simultaneously with the increased activity of the direct oxidative pathway, a diminished production of carbon-14 labelled carbon dioxide from glucose-6-^{14}C takes place in the presence of insulin Similar shifts, but in the opposite direction, have been reported by Lerman[8,9], who found that the hexose monophosphate shunt was depressed in galactose-fed and in old rats while production of carbon-14 labelled carbon dioxide via the Embden–Meyerhof and Krebs cycle was increased Our experiments have shown that, in diabetes also, the hexose monophosphate shunt is depressed; the corresponding increase in carbon-14 labelled carbon dioxide production from glucose-6-^{14}C was, however, not observed, possibly because the absolute amount of radioactivity resulting from this pathway was so low that small differences could not be detected. It would appear that at least one common denominator exists in all three of these cataractogenic conditions, namely, a diminished activity of the hexose monophosphate shunt

Isolation of an Unknown Auxin from a Solution of Indole-3-Acetic Acid labelled with Carbon-14

IT is desirable in certain investigations in metabolism to work with as stable a compound as possible, or use as an indicator of the basic structure of the compound some form of marker or tag Such is the case with plant growth regulators and auxins

In the case of indole-3-acetic acid (IAA) it is known that the carboxyl group is quite reactive and even the methylene group may be degraded Thus, there is advantage in labelling an atom in one of the rings This has been done by Pichat *et al* [1] at position 2 in the indole ring

This material was obtained for work on translocation of IAA in the *Avena* coleoptile Approximately four months after its synthesis very little activity could be found in the labelled material The substance was known to be unstable from radiolysis (internal irradiation from the isotope) by the carbon-14 on some part of the molecule

The solution contained 2 5 mgm of IAA in methanol Its specific activity was originally 6 9 mc /mm No suggestion has been made as to the degradation product(s) This may prove to be one of those recently suggested by Fawcett[2]

In order to determine the purity of the solution and to find out where the radioactivity was located, that is, if in the IAA or some breakdown product, a chromatographic separation of the methanol solution was made

This had been reported (private communication) by K V Thimann in June 1960 He had made a chromatographic analysis of the solution and found that most of the radioactivity was in a spot near the solvent front and very little in the IAA at 0 30 The method of Stowe and Thimann[3] was used with isopropanol/ammonia/water (10 1 1) to identify the auxin The chromatogram for the IAA solution gave two spots when sprayed with Salkowski reagent[4], one at about R_F 0·33 (for IAA) and another (salmon-orange colour) at about R_F 0 90

The strip was placed under a Geiger counter and read for radioactivity All of the counts were at R_F 0 90 and none at R_F 0 33 This corroborated the results of Thimann

A test was made to determine which compound was an active auxin The spots (before development with Salkowski) were cut from the paper strip, placed in cold peroxide-free ether in flasks in the refrigerator overnight The flasks (30 ml) were placed on a shaker for a short time, then the ether was evaporated down before being applied to 1 5 per cent agar medium

A Went *Avena* bioassay was run on these materials A 50 μgm /l sample was run as a control This gave a normal curvature of about 13°

The ether extracts from the IAA spot produced curvature However, when the eluted spot was sprayed with Salkowski after extraction, an easily detectable spot was developed This indicated that much of the IAA was not eluted from the spot by ether

When the same test was made on the *X* substance, curvature resulted On spraying with Salkowski reagent, no colour developed at the spot for the *X* compound

One further test was conducted to see if possibly the IAA was being carried along to the *X* spot and resulting in a tail between the two spots There was no radioactivity in any area other than at the *X* spot of R_F about 0 90

Strips were cut from the paper between the IAA spot and *X* spot and eluted with ether No curvature resulted from these areas, whereas it consistently occurred for the *X* compound

Because of the lack of more compound (original sample only 2 5 mgm) only three runs were made on the *X* compound and the blank areas between the two spots

An attempt was made to obtain an ultra-violet spectrum for the substance, but due to interfering (brown) degradation colours of indole derivatives, no satisfactory spectrum could be obtained

Although closer to the chemical structure of IAA, the new auxin described by Post[6], skatylglyoxal hydrate, does not appear to coincide in both requirements Its *Avena* curvature seems similar, especially in being more active than IAA, but the chromatographic analysis does not behave in the same pattern, although in no case was the solvent system exactly the same

An unknown, *X* compound was shown to contain all the radioactivity from an initial preparation of β-(^{14}C-2-indole) acetic acid This compound also possessed auxin properties as shown by its *Avena* coleoptile curvature ability Further investigations will be attempted when more of the labelled IAA is available and more quantitative runs can be made

Other compounds were run in both the bioassay and chromatographic analysis, but none possessed the characteristics of the *X* compound Such compounds as indole, skatole, mixtures of IAA and the former two, other indole compounds, and the two non-indolic auxins of Crosby and Vlitos[5], 1-docosanol and 1-octadecanol, were run None was found to fit the dual patterns of the *X* compound , none showed *Avena* curvature It does not seem likely that the two compounds of Crosby and Vlitos could be formed from the original compounds or the degradation products in the Pichat synthesis[1]

Distribution of Trypsin Inhibitors in the Sera of Various Animals

TRYPSIN inhibitors have been found in pancreas, serum, colostrum, egg-white, soya bean, and lima bean[1] They have all been crystallized except from egg-white[2] Thus, examination of the distribution of trypsin inhibitors in proteins of them appears to be out of the question Recently, Nakamura *et al* [3] have demonstrated, by two-dimensional paper electrophoresis, that two trypsin inhibitors were contained in the extract of soya-bean Hence the distribution of trypsin inhibitors in other biological fluids deserves to be re-investigated to see whether there are also two inhibitors in them or not

In Fig 1 is shown one of the 'crossing diagrams' of human serum against trypsin The electropherogram shown was obtained by two-dimensional electrophoresis as follows Human serum was applied on line *AB* and the first electrophoresis was carried out in direction 1 A solution of trypsin was then applied on line *XY* and the second electrophoresis was carried out in direction 2 Under the given experimental conditions, trypsin migrates towards the cathode and serum proteins towards the anode. Thus the former migrates over the lines of the latter. As can be seen from Fig 1, the lines of serum proteins were partially digested by trypsin In this way the front of the trypsin line, which is named the crossing diagram' of the serum against trypsin, appeared across the zones of serum proteins It shows two grooves (or peaks, if viewed conversely), one in the zone of α_1-globulin and the other in that of α_2-globulin At the grooves in the line, trypsin is retarded The retardation of the migration of trypsin must have been caused by the reaction with substances in serum, which combined with it and inhibited its activity Therefore from the 'crossing diagram' of serum proteins against trypsin the distribution of trypsin inhibitors in serum can be investigated easily Fig 1 shows that human serum contains two trypsin inhibitors, one in α_1- and the other in α_2-globulin

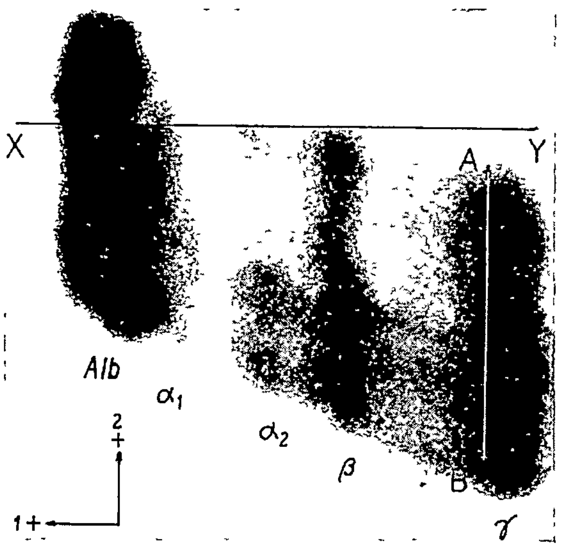

Fig 1 'Crossing diagram' of human serum against trypsin First electrophoresis, 0 04 ml /6 cm of human serum were applied on line *AB* and run at 100 V for 16 hr Second electrophoresis, after the first one, 0 1 ml /14 cm of 1 5 per cent crystallized trypsin solution was applied on line *XY*, and run at 100 V for 8 hr Barbiturate buffer, *p*H 8 6 and ionic strength 0 05 Stained with bromophenol blue

Table 1 shows some of the results obtained by the same method with sera of various animals From the results obtained so far, it can be inferred that sera of many animals contain two trypsin inhibitors (although some contain only one) and the distribution of them in the serum proteins is characteristic of the species The circumstances are the same as for the 'crossing diagrams' of serum against protein *J* of jack beans[4]

Table 1 DISTRIBUTION OF TRYPSIN INHIBITORS IN SERA OF VARIOUS ANIMALS

Animal	Albumin		α		β γ
Human		+++	+		
Dog				++	
Cat		++		++	
Horse	++		++		
Cattle			+++		
Sheep			+++	+	
Pig			+++		
Rabbit		+++		+	
Guinea pig		+++		+	

The number of (+) denotes rough estimation

The method of two-dimensional electrophoresis to obtain the 'crossing diagram' is not strictly quantitative, but from the height of the peak, if other conditions were the same, a rough comparison can be made between the sera of different animals In human sera particularly, the changes of distribution of trypsin inhibitors in diseases deserve further investigation

Trehalose in the Cellular Slime Mould *Dictyostelium mucoroides*

IN 1925 Iwanoff[1] demonstrated the presence of the non-reducing disaccharide, trehalose, in isolated spores of the acellular slime mould, *Reticularia lycoperdon* (Myxomycetes). Recent work[2] on soluble carbohydrates in the cellular slime moulds have not mentioned the presence or absence of this sugar The present report concerns the occurrence of trehalose in the cellular slime mould *Dictyostelium mucoroides* (Acrasiales), and preliminary work on the role of this sugar during development

The fruiting body of *D mucoroides* consists of a long cellular stalk that bears a spherical mass of spores On germination each spore releases a small 'amœba' These amœbæ feed on bacteria, grow, and divide When the bacteria have been consumed, aggregation of the amœbæ occurs at various locations on the culture dish forming cigar-shaped masses of cells, pseudoplasmodia The pseudoplasmodia migrate and each constructs a stalk as it does so. Eventually migration ceases and those cells that have not become stalk cells are transformed into spores In certain strains of this species post-aggregative development results in the formation of a multi-cellular encystment stage, the macrocyst, instead of a fruiting body The present work is concerned mainly with spores and macrocysts, but vegetative amœbæ and pseudoplasmodia were also investigated

Spores were plated together with *Escherichia coli* on the nutrient agar medium of Bonner[3]. When fruiting occurred, the spores were harvested, washed, and homogenized in a glass homogenizer with 80 per cent methanol Macrocysts were collected by plating spores of the proper strain on the same medium and flooding the culture with about 3 ml of sterile distilled water Under these conditions very few fruiting bodies and large numbers of macrocysts were formed. The latter were collected, washed, and homogenized in 80 per cent methanol Following centrifugation the alcoholic extract was evaporated to dryness and redissolved in distilled water This solution was chromatographed on Whatman No 1 chromatographic paper for the separation, elution, and quantitative determination of carbohydrates[4] The solvent systems used were *n*-butanol/95 per cent ethanol/acetone/water (5 4 3 2), *n*-propanol/ethyl acetate/water (7 1 2), ethyl acetate/pyridine/water (8 · 2 1), and *n*-butanol/acetic acid/water (4 1 : 5)

When extracts of various stages of the life-cycle were analysed by paper chromatography, large amounts of an alcohol-soluble carbohydrate were detected in the spores and macrocysts but not in the other stages This substance migrated with known disaccharides and was shown to be trehalose by the following criteria it was non-reducing unless oxidized first with periodate[4] After elution from the chromatogram it reacted with the anthrone reagent[5] and on hydrolysis with 1 *N* hydrochloric acid liberated only glucose as judged by use of the glucose oxidase system ('Glucostat', obtained from the Worthington Biochemical Corp , Freehold, New Jersey, was used for the assay of glucose) When an eluted sample was co-chromatographed with authentic trehalose, no separation was observed in the four solvent systems listed above Treatment of an eluted sample with a partially purified preparation[6] of the specific hydrolytic enzyme, trehalase, readily hydrolysed the sample exclusively to glucose

Quantitative work carried out on isolated spores showed that trehalose constituted more than 7 per cent of the dry weight, and a similar concentration was found for the macrocysts. Trehalose could not be detected in the other life-cycle stages (limits of detection < 0 1 per cent of the dry weight) but small amounts of glucose were always present as judged by paper chromatography Fructose has been reported present in *D discoideum*[2], but we have not detected this sugar in our material It appears that trehalose and small amounts of glucose are the main, and perhaps the only, soluble carbohydrates present in *D mucoroides*

The restriction of trehalose to the spores and macrocysts implied that this sugar was utilized during germination Accordingly, we incubated spores for 12 hr under conditions conducive to germination, and then analysed the resulting amœbæ for trehalose content No trehalose was detected Although a more complete balance sheet is necessary before any conclusions can be drawn, it appears that trehalose might play some part in the germination process of this organism, possibly as an energy source for this activity

Trehalose has been found in large amounts in the resistant or dormant stages of several other organisms such as the ascospores of *Neurospora*[7], the eggs of *Ascaris*[8] and *Bombyx mori*[9], and the resistant embryo of *Artemia*[10] In addition, we have found large amounts of trehalose in the desiccatable eggs of *Aedes aegypti* and dried statoblasts of the bryozoan *Plumatella* (unpublished observations). Moreover, in the majority of these cases the amount of trehalose decreases sharply during the resumption of 'activity', again indicating a role for this sugar during the transition from the dormant to the active state We are at present extending our observations to resistant stages of representatives from other phyla

Structural Investigation of a Laminaran isolated from *Eisenia bicyclis*

In 1939 Nisizawa[1] isolated a soluble laminaran from the fronds of the brown alga, *Eisenia bicyclis* No further investigations, however, were made at that time, beyond observations on some of its chemical properties and behaviour towards enzymes Recent detailed structural investigations are now reported

In contrast to the modified Kylin method previously used by Nisizawa[1], the small pieces of frond were extracted with about ten times their volume of 1 per cent hydrochloric acid at room temperature for five days. The crude laminaran was precipitated from the extract by the addition of five volumes of

methanol. Purification was effected by repeated treatment with charcoal and precipitation with methanol from aqueous solutions

The final product, obtained as a white powder after electrodialysis, was very soluble in water and nitrogen-free (Kjeldahl) Ash (direct), 0·1 per cent Found, C, 44 44 per cent, H, 6·22 per cent, $(C_6H_{10}O_5)_n$, requires, C, 44 44 per cent, H, 6 17 per cent

Eisenia laminaran reduced hypoiodite equivalent to an average chain-length of 18 This is close to the value, 21, obtained by cryoscopy[1] and thus almost all molecules of this laminaran, in contrast to the insoluble[2,4,5] and soluble[2] laminarans from the genus *Laminaria*, appear to possess a reducing group No mannitol was detected by paper chromatography of the laminaran hydrolysate after removing glucose by alkaline degradation and by fermentation

The specific rotation of the laminaran was the same as that reported by Nisizawa[1], $[\alpha]_D^{20}$, − 45 5° (in water), although the extraction method was essentially different The acetyl derivative had $[\alpha]_D^{20}$, − 42 2° (in chloroform) Intrinsic viscosities were 1·35 (in water) for free laminaran, and 3 87 (in *n*-cresol) and 5 9 (in chloroform) for laminaran acetate.

The laminaran consumed 0 73 mole periodate and released 0 37 mole formic acid per mole anhydroglucose when oxidized by 0 03 *M* sodium metaperiodate at room temperature for 24 hr. These values were much higher than those for insoluble laminaran[3,4]

To obtain partial hydrolysis products, laminaran (150 gm) was acetolysed at 35° C for 96 hr and the mixture of deacetylated saccharides (121 gm) was fractionated by charcoal-'Celite' column chromatography Ten different oligosaccharides were isolated The yield $[\alpha]_D$, D P and the identity of disaccharides produced from the oligosaccharides on partial acid hydrolysis are shown in Table 1 Of the ten oligosaccharides obtained, two were disaccharides, four were trisaccharides and another four were tetrasaccharides. All these appeared to contain only β-1 3- and/or β-1 6-links Table 2 shows the periodate oxidation data for these oligosaccharides and their possible structures Maximum periodate consumption and formic acid release increased by 2 moles and 1 mole, respectively, for some oligosaccharides when 0 06 *M* periodate was used in place of 0 03 *M*, whereas the values for the others were the same at both periodate concentrations. The former group may be terminated by a reducing glucose residue which was subject to over-oxidation, possibly joined by a β-1 · 3-link, whereas the latter group may be terminated by a reducing residue which was resistant to over-oxidation, possibly being joined by a β-1 6-link. From the maximum values obtained on periodate oxidation and the results in Table 1, the fractions from *F*1 to *F*6 were identified as gentiobiose, laminaribiose, gentiotriose and 6-β-laminaribiosylglucose, laminaritriose and 3-β-gentiobiosylglucose, respectively

Table 2

Oligosaccharide fraction	Maximum value observed (moles) Periodate	Maximum value observed (moles) Formic acid	Possible structure	Maximum theoretical value (moles) Periodate	Maximum theoretical value (moles) Formic acid

*F*10	5 2 (2 8)	2 9 (2 7)	G1–3G1–3G1–3 (G)	5 (3)	4 (3)

Note G, β-linked glucose residue, (G), glucose residue with reducing group For the figures without parentheses, 0 06 *M* sodium metaperiodate, at room temperature, for 144 hr For the figures with parentheses, 0 03 *M* sodium metaperiodate, at room temperature, for 24 hr

Although 3 6-di-*O*-β-glucosylglucose would be expected to produce the same maximum values on periodate oxidation as laminaritriose when 0 06 *M* periodate was used, they may be differentiated on the basis of their maximum values in 0 03 *M* periodate since only laminaritriose would be expected to show a lowered value Furthermore, *F*5 did not give gentiobiose on partial acid hydrolysis and gave glucose after being oxidized with periodate and hydrolysed. This behaviour indicates the absence of 3 6-di-glucosylglucose The absence of this trisaccharide suggests in all probability a linear structure for *Eisenia*- laminaran Results with methylation also support this assumption Although three different methylglucoses were obtained, one of which was identified as 2 3 4 6-tetramethylglucose and the other two as 2 3 4- and 2 4 6-trimethylglucoses on the basis of their methoxyl contents and R_F-values, no dimethyl glucoses were found on the paper chromatogram Of the four different tetrasaccharides, *F*8 and *F*9 could not be identified, while the characteristic patterns of maximum values for *F*7 and *F*10 suggest that the latter two may be gentiotetraose and laminaritetraose, respectively It should be noted that gentiotriose and gentiotetraose have never been found in the partial acid hydrolysates of *Laminaria* laminarans[2,3]

The alkaline degradation of *Eisenia* laminaran in 4 *N* as well as 2 *N* sodium hydroxide solutions at 30° C ceased after the loss of about one-third of the weight of the laminaran, whereas periodate uptake and formic acid release by the residual polysaccharide was nearly 1 4 times that of untreated laminaran The part of the laminaran removed appears, therefore, to consist of β-1 3-linked glucose residues which would not contribute to the periodate consumption. The cessation of alkaline degradation may reflect the presence of a β-1 6-linkage in the molecule, as discussed in ref 6 Thus it may be suggested that *Eisenia* laminaran is a linear β-glucan with a D P. of about 20 containing both 1,3 and 1,6 linkages (in the approximate proportion 2 1), and since gentiotetraose was isolated from this laminaran by partial acid hydrolysis, at least three β-1 6-linked glucose residues must be present as a block among the β-1 3-linked residues, probably occupying about the central region of the molecule

We are indebted to Prof T Miwa for his interest and encouragement and to Dr B A. Stone, who kindly read this communication.

Occurrence of Sedoheptulose in Carpophores and Basidiospores of *Inocybe* Species

ALTHOUGH basidiospores of various xylophilous, coprophilous and lignicolous Hymenomycetes germinate quite readily, and in high percentage, those from mushrooms with proved mycorrhizal associations rarely, if ever, respond to standard mycological techniques Among the latter are species of *Amanita, Lactarius, Cortinarius, Russula, Hygrophorus,* and *Boletus* After completing an extensive series of experiments on the above problem, Kneebone[1] concluded that the low respiratory-rate of the spores is probably not limited by a lack of metabolic reserves but rather by some deficiency of the organism which prevents efficient utilization of available respiratory substrates

We are investigating physiologically active constituents in the carpophores of various species of *Panaeolus* and *Inocybe* native to the Pacific northwest of the United States *Inocybe* species are thought to be mycorrhizally associated and have proved extremely difficult to sub-culture either from carpophore tissues or spores Information on the nature of the carbohydrate reserves of carpophores and spores was needed

In a paper chromatographic study of extracts of carpophores of 91 species representing 29 genera of fleshy fungi, Bonnet[2] found mannitol in 86, trehalose in 82, and glucose in 34 The results of Sussman and Lingappa[3] suggested that trehalose is the probable substrate the utilization of which is correlated with the germination of ascospores of *Neurospora tetrasperma* However, Kneebone had reported that the stimulatory effects of heat shock and of furfural on the germination of *Neurospora* ascospores could not be duplicated on spores of the mycorrhizal-associated fungi which he tested

Dried carpophores of several species of *Inocybe*, ground to a No 40 powder, were each shaken for 18–24 hr at room temperature with 20 ml of 70 per cent ethanol per gram of powder The marcs were discarded and the clear filtrates extracted with petroleum ether to reduce the fat and oil contents

Following evaporation *in vacuo* at 38° C , the residues were dissolved in 1 5 ml of 50 per cent isopropanol, transferred to vials and chilled overnight to remove interfering salts[4] Portions (25–50 μl) were spotted on sheets of Whatman No 1 filter paper and irrigated by the circular method of Rutter[5] in 150-mm Petri dishes with *n*-butanol/pyridine/water (6 4 3) or *n*-butanol/ethanol/water (10 1.2), for 2 and 7 hr respectively When processed with the ammoniacal silver nitrate spray of Partridge[6] or the periodate–permanganate spray of Lemieux and Bauer[7], three to five distinct zones appeared. One of these was identified as mannitol by comparison of its R_F value with that of reference mannitol

Volemitol (D-*manno*-D-*talo*-heptitol[8]) was isolated many years ago by Bourquelot[9] from carpophores of *Lactarius volemus* The possibility that seven-carbon saccharides might also occur in *Inocybe* species, plus the apparent specificity of colour reactions for ketoses reported by Benvenue and Williams[10], prompted us to utilize a spray containing orcinol After irrigation in the solvent systems previously mentioned, the papers were sprayed with water-saturated *n*-butanol–orcinol–trichloracetic acid[11] and heated for 10 min at 105° C Blue bands with low R_F values were noted from carpophore extracts of the following species of *Inocybe* · *picrosma* Stuntz, *kauffmanii* A H Smith, *cinnamomea* A H Smith, *lilacina* (Boud) Kauff , *mixtilis* (Britz) Sacc sensu Kuhner, *subdestricta* Kauff , *geophylla* (Fr.) Quél var *lateritia* Weinm , *agglutinata* Peck, and *lacera* (Fr) Quél *I albodisca* Peck, *I sororia* Kauff , and *I xanthomelas* Boursier and Kuhner in Kuhner did not show detectable amounts

The concentrations of the ketoheptuloses in the extracts were very low. *I kauffmanii* gave the strongest tests but our supply of dried carpophores was limited The mobilities of ketoheptulose from *I cinnamomea* and *I kauffmanii* extracts, which had been partially purified by a series of treatments including defatting, deproteinization, and ion-exchange were compared with those of crystalline standards of L-*gala*-heptulose, D-*gluco*-heptulose, D-*manno*-heptulose, and D-*allo*-heptulose Partially purified sedoheptuloses from *Cotyledon glauca* Baker and *Sedum spectabile* Bor were also included

A 48-hr descending irrigation technique, which allowed the solvent mixture (*n*-butanol–pyridine–water) to drip off the paper, was necessary for clear-cut separation Although comparative R_F values could not be obtained, the mobilities of heptulose from the two species of *Inocybe* were identical with reference sedoheptulose, separately and in admixture

The smooth-walled spores of *I cinnamomea* were subjected to low-temperature cavitation in a Raytheon oscillator (10 kc /s) About 60 min were required to disrupt approximately 90 per cent of 100 mgm of spores in 20 ml of water together with some 0 2 mm diameter glass paving beads The mobility of spore heptulose in the descending system was the same as that obtained from the sporocarps of *I cinnamomea* A second ketose was also present in the partially purified spore extract It gave a bright yellow colour with the spray containing orcinol and had a mobility similar to that of fructose Angular spores from *I mixtilis* and *I xanthomelas* were far more refractory to treatment and similar amounts did not give positive heptulose tests Much greater quantities of spores would be required to obtain enough heptulose for positive chemical identification This would indeed be difficult considering that approximately 6,000 caps of *I. cinnamomea*, averaging about 1 in in diameter, yielded only 800 mgm of spores

This constitutes the first report of the occurrence of sedoheptulose in extracts of mushroom tissues

The possibility that one of the oxidative pathways in these spores may proceed through the pentose-phosphate cycle remains to be proved

We are indebted to Dr N K. Richtmyer, National Institutes of Health, Bethesda, Md , for suggestions and supplies of several different crystalline heptuloses and heptulosans, and to Dr Howard Douglas, Department of Microbiology, University of Washington, for the use of the Raytheon oscillator The support of the U S Public Health Service grant No *RG*-7515 is gratefully acknowledged

Inhibition of Dopamine β Oxidase by Adrenalone

WE have reported that several structural analogues of dopamine are inhibitors of dopamine β oxidase Dopamine β oxidase catalyses the conversion of dopamine to norepinephrine and the enzyme activity was determined by fluorimetric estimation of norepinephrine formed, by the method of von Euler *et al* [1] However, when adrenalone was tested as a possible inhibitor of dopamine β oxidase, the fluorimetric assay of norepinephrine was unsatisfactory This was due to the fluorescence quenching of norepinephrine by adrenalone The fluorescence quenching by other keto compounds has been reported[2], and such quenching may represent a serious obstacle to the fluorimetric determination of catecholamines in the presence of ketones such as adrenalone

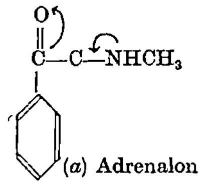
Therefore, in these investigations, where adrenalone was tested as a possible inhibitor of dopamine β oxidase, dopamine-^{14}C was used as a substrate The amount of dopamine-^{14}C which disappeared from the incubation mixture as well as the norepinephrine-^{14}C formed in the incubation mixture were calculated from the radioactivity of each of these compounds The incubation procedure as well as the separation of dopamine-^{14}C from norepinephrine-^{14}C was carried out as already described by us (ref 3) The degree of the rate of inhibition of dopamine β oxidase was determined by comparing the amount of norepinephrine-^{14}C formed and the amount of dopamine-^{14}C which disappeared in an incubation mixture which contained only the substrate and in an incubation mixture which contained adrenalone and the substrate

Table 1 shows the rate of inhibition of adrenalone on dopamine to norepinephrine conversion For comparison, the rate of inhibition of dopamine to norepinephrine by epinine is also presented in Table 1 It is evident that adrenalone is a more potent inhibitor of the dopamine to norepinephrine conversion than epinine

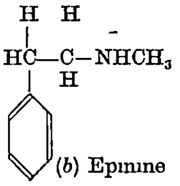
Table 1 INHIBITION OF DOPAMINE TO NOREPINEPHRINE CONVERSION BY ADRENALONE

Amount added (μmoles)			Norepinephrine formed	Dopamine disappearing
1 5	none	none	0 60 ± 0 06	0 80 ± 0 08
1 5	none	12	0 45 ± 0 05	not estimated
1 5	12	none	0 20 ± 0 02	1 2 ± 0 1

The structure of adrenalone (*a*) differs from epinine (*b*) only in that the former possesses a ketone group in the β position.



(*a*) Adrenalone



(*b*) Epinine

The electron-withdrawing effect of the carbonyl group in adrenalone will tend to make the nitrogen of the secondary amino group less basic This is consistent with our previous findings that primary amines (which are weaker bases) are also stronger inhibitors of dopamine β oxidase[3] A second possibility is that the electrophilic centre of adrenalone interacts with the nucleophilic centre on the enzyme surface

It should be stressed that while epinine itself is also a substrate of dopamine β oxidase and its inhibition of dopamine to norepinephrine conversion is due to a substrate competition, it is more likely that adrenalone is a non-competitive inhibitor

Acidic Dissociation of 7 : 9-Dialkylguanines and its Possible Relation to Mutagenic Properties of Alkylating Agents

Watson and Crick[1] proposed as a possible mechanism for mutation that changes in the tautomeric structure of a base of deoxyribonucleic acid (DNA) could induce its pairing with an anomalous base In considering the possible correlation between the action of alkylating agents on DNA and the mutagenic activity of these agents, we mentioned in a recent report[2] that it was not obvious how the initial action of alkylation of DNA, which has been shown to occur at $N_{(7)}$ of guanine moieties[3,4], could affect base-pairing in DNA according to the Watson–Crick model We therefore suggested that the subsequent loss of the alkylated guanine moiety from DNA (refs 4 and 5) might be the chemical action necessary for mutation to result

We now wish to present preliminary evidence that alkylation of guanine nucleosides or other 9-substituted guanines at $N_{(7)}$ results in an immediate change in the molecular structure of these bases at neutral *p*H in that part of the molecule involved in hydrogen-

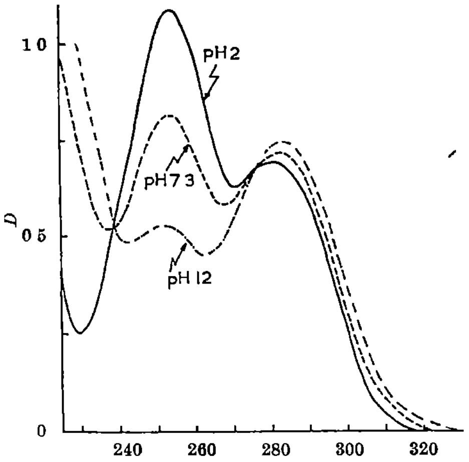

Fig 1 Absorption spectra of 7 9-di-(2′-hydroxyethyl)guanine (0 0267 mgm /ml) at *p*H 2, *p*H 7 3 and *p*H 12, 20°

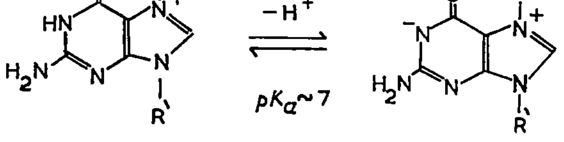
bonding as required by the Watson–Crick model This follows from investigation of the acidic dissociation of 7 9-disubstituted guanines by spectrophotometric titration The absence of a basic *pKa* in the region of 3 for 7 9-dialkylguanines has previously been noted[6] However, with increasing *p*H in the region of *p*H 7 the absorption spectrum of 7 9-dialkylguanines changes, the change being complete at about *p*H 9, and these changes are consistent with the occurrence of an acidic dissociation in the region of *p*H 7, that is about two units of *p*H lower than for the corresponding 7 or 9-monosubstituted guanines Fig 1 shows spectra for 7 9-di-(2′-hydroxyethyl)guanine and Fig 2 for 7-methylguanosine

The spectrum of the molecular species of 7 9-disubstituted guanines with zero net charge, that is, at *p*H greater than 9, resembles that of 7- or 9-monosubstituted guanines in alkali This suggests that the proton has been lost from the $N_{(1)}$ ring-nitrogen atom Conventional formulation of these bases must therefore be as a zwitterion, as represented in (I), or with the negative charge on the extranuclear oxygen atom. It may be noted that the dissociated proton is normally required in formation of one of the hydrogen bonds between guanine and cytosine moieties of DNA according to the Watson–Crick model



(I)

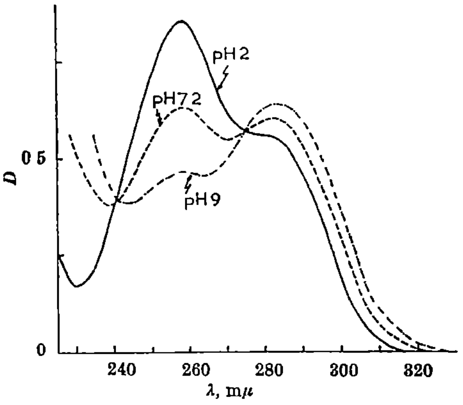


Fig 2 Absorption spectra of 7-methylguanosine (0 0234 mgm / ml.) at *p*H 2, *p*H 7 2, and *p*H 9, 20°

It appears, therefore, that at neutral *p*H the effect of alkylation of DNA at $N_{(7)}$ of guanine moieties would be to weaken the bonding between guanine and cytosine, since the tendency for the alkylated guanine to exist in the form shown in (I) would be much greater than for normal guanine Furthermore, it is possible that during duplication of DNA the specificity of base-pairing would be weakened, since the number of hydrogen bonds which could form between alkylated guanine in form (I) and cytosine would be reduced by one It may be noted that the configuration of (I) is such as to permit two hydrogen bonds to form with thymine, involving $N_{(1)}$ and the extranuclear amino group of the guanine moiety (Fig. 3) The configuration of this base-pair is such that it could fit into the DNA structure in place of a normal guanine-cytosine pair

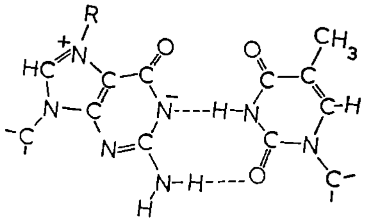

Fig 3 Possible base-pairing of alkylated guanine and thymine

We suggest, therefore, that the mutagenic action of the alkylating agents could be due to their ability to alkylate DNA at $N_{(7)}$ of guanine moieties, thus strengthening the acidity of the —NH—CO— group in alkylated guanine so that its dissociation would cause a tendency for alkylated guanine to base-pair with thymine instead of cytosine during DNA duplication. After such anomalous base-pairing, in subsequent DNA duplications an adenine-thymine pair would replace the original alkylated guanine-cytosine pair

PHYSIOLOGY

A Central Action of 5-Hydroxytryptamine and Noradrenaline

THE experiments reported here were based on the observation that an intra-carotid or intravenous injection of *d*-lysergic acid diethylamide (LSD-25) depresses the transmission of orthodromic impulses through the lateral geniculate nucleus of the cat[1]. The nature of this depression suggests that LSD-25 can compete with the excitatory transmitter for post-synaptic receptor sites. Consequently the known antagonism between LSD-25 and 5-hydroxytryptamine (5-HT) at receptors of smooth muscle[2] indicates the possibility that the as yet unknown central excitatory transmitter might be related to 5-HT. It is probable that the failure to demonstrate an action of 5-HT on these neurones[1] was due to the blood-brain barrier, which is relatively impermeable to this substance[3].

In the present investigation, 5-HT and a series of structurally similar compounds, including some catecholamines, have been applied electrophoretically to single neurones in the lateral geniculate nucleus of a cat anæsthetized with pentobarbital. The direct extracellular application of drugs circumvents the blood-brain barrier and the actions of four different compounds could be compared on single cells by the use of five-barrel electrodes[4]. The spike responses, 0·2–1·0 mV in amplitude and of negative–positive voltage sequence, were recorded by means of the central barrel of the electrode, which contained 4 *M* sodium chloride. Most substances were passed as cations from saturated aqueous solutions of *p*H 3–4. These included 5-HT creatinine sulphate, tryptamine, bufotenine, LSD-25, 2-bromo-LSD(BOL-148), psilocin[5], noradrenaline bitartrate, adrenaline bitartrate and 3-hydroxytyramine. L-Glutamic acid and psilocybin[5] were applied as anions from solutions of the sodium salt at *p*H 8.

When an electrophoretic current was used to apply cations from a saturated aqueous solution of 5-HT creatinine sulphate, there was suppression of the orthodromic responses of neurones which responded monosynaptically, and occasionally repetitively, to an optic nerve volley. Such was not the case when the electrode contained creatinine sulphate instead of the 5-HT creatinine sulphate complex, hence it is reasonable to assume that the depression observed with the complex was due to 5-HT. The latency of this effect was reciprocally related to the magnitude of the electrophoretic current and for currents of 20–100 mμamp was about 10–2 sec. Following the termination of the current flow the spike responses recovered in 5–20 sec. When L-glutamate was applied from another barrel, the excitation of the neurones, measured by the frequency of the firing evoked by the amino-acid[4], was unaltered by 5-HT. Furthermore, the antidromic spike responses of these neurones, evoked by stimulation of the optic radiation beneath the ipsilateral gyrus marginalis of the cerebral cortex, were unaffected by 5-HT. These actions of 5-HT are illustrated in Fig. 1.

All the substances mentioned here, except creatinine and L-glutamic acid, had actions identical with those of 5-HT. Although it is difficult to compare various substances quantitatively by these electrophoretic techniques[4], an approximate estimate of the potency of the compounds can be given. 5-HT was the most effective depressant of these cells, as determined by the magnitude of the electrophoretic current necessary to block the excitation of single cells within a given time. The other agents were less effective, the descending order of potency being tryptamine, bufotenine, LSD-25, psilocin and psilocybin, 3-hydroxytyramine, noradrenaline and adrenaline, BOL-148. The latter compound had a very weak action. Several experiments were carried out to test whether BOL-148 interfered with the effect produced by 5-HT and no antagonism could be detected. In addition to being less effective than 5-HT, some of the other active compounds were more prolonged in their action after the applying current was terminated. Thus the recovery from an application of LSD-25 using an electrophoretic current which produced depression in 30–40 sec often took 10–15 min.

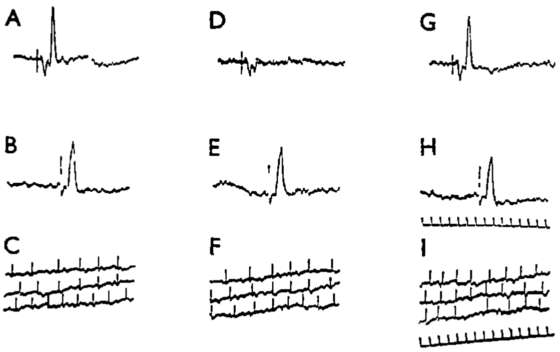

Fig. 1. Spike responses of a single neurone in the lateral geniculate nucleus responding monosynaptically to a contralateral optic nerve volley (*A*, *D*, *G*), antidromically to a stimulus to the ipsilateral optic radiation (*B*, *E*, *H*) and repetitively to L-glutamic acid (*C*, *F*, *I*) which was applied from one barrel of a five-barrel electrode using an anionic current of 100 mμamp. After the control responses *A* and *B*, a current of 20 mμamp. passed cations from an aqueous solution of 5-HT creatinine sulphate (*p*H 3·3) for 12 sec. The responses *D* and *E* were recorded 5–7 sec. after the current started and *G* and *H*, 5–7 sec. after it terminated. *C*, *F*, *I* were recorded with lower amplification (all spikes are approximately 0·5 mV. in amplitude) in another series. *C*, control; *F*, 31 sec. after a current of 20 mμamp. passed 5-HT creatinine sulphate into the environment of the cell. At this time orthodromic responses were suppressed. *I*, 2 min. after the 5-HT application ceased, the orthodromic responses having recovered fully. Time, msec. for *A*, *B*, *D*, *E*, *G*, *H* beneath *H*; 10 msec. for *C*, *F*, *I* beneath *I*

Several conclusions can be drawn from these observations.

The failure of 5-HT to affect either the antidromic firing of these neurones or the firing evoked by L-glutamic acid indicates that 5-HT does not significantly modify the membrane conductance of the cells. Thus it is very unlikely that it was combining with the sub-synaptic receptors of inhibitory synapses and activating the associated receptor membrane, or that it was depressing the electrically excitable membrane of the cells in some other fashion. It is probable that the depression of the orthodromic responses was due to a reversible interaction between 5-HT and the receptors at excitatory synapses which are specialized for the transmitter released from the optic tract terminals. However, the possibility that 5-HT was depressing the release of this transmitter cannot be excluded until the transmitter is identified and applied to the synapses.

The antagonism which is exhibited between 5-HT and the other compounds, when tested on smooth muscle, was not apparent at these central synapses. Indeed these 'antimetabolites'[3] had actions similar to that of 5-HT. Presumably all these depressants interacted with the same receptors, the potency and the duration of action of a particular compound being determined by the stability of the drug-receptor complex

The possible interaction of these substances with post-synaptic transmitter receptors suggests that the excitatory transmitter acting on the lateral geniculate neurones might be related structurally to them Experiments are proceeding with a large number of indoles and catecholamines in order to determine those structural features necessary for a compound to interact with the transmitter receptors

Grateful acknowledgment is made for the following gifts 5-HT creatinine sulphate, creatinine sulphate and bufotenine (Dr M E Speeter, The Upjohn Co , Michigan), LSD-25 and BOL-148 (Sandoz, Ltd , Basle), psilocin and psilocybin (Dr Hofmann, Sandoz, Ltd)

Hormones and Electrolyte Excretion in Sheep

MERINO sheep in hot environments effectively reduce the rate of excretion of water but that of sodium and potassium may not change, and often increases during periods of dehydration[1]. Renal hæmodynamics may be concerned in this adjustment of kidney function but endocrine activity has been examined in the search for possible mechanisms

Merino ewes were accustomed to life in metabolic cages on a fixed feeding regime at room temperatures between 22° and 24° C Electrolyte excretion was followed throughout periods of 36 hr using a fraction collector to take specimens at ½ hr intervals There was considerable variation in excretion, mainly following morning feeding which produced a rise in sodium and potassium output by day and a low rate of excretion at night Sheep were therefore trained to take lucerne chaff during a period of 3 hr between 10 a m and 1 p m It was observed that within 20–30 min of beginning to feed, normally alkaline (pH 8 2–8 6) urine became acid (pH 5 2–6 6) for about 1 hr While feeding continued (Fig 1c) the urine returned to a pH of 8 2 Production of saliva with a high bicarbonate content could leave the blood depleted of alkali and an acid urine could result

Infusion of small amounts of hormone intravenously over an hour was undertaken Six hormones were examined Mixed arginine and lysine vasopressin ('Pitressin'), infused at the rate of 12 milliunits/min , had two types of effect At urine flows lower than 1 ml /min there was an increase of water, sodium, potassium and chloride excretion per unit of time (Fig 1a) At flows greater than 2 ml /min there was a reduction of flow of urine and increased output of electrolyte The osmolar excretion-rate increased at both high and low levels of urine flow under the influence of vasopressin This occurred both in the field (the tropics at 21° S latitude) and in the laboratory During diuresis the osmolarity of urine was 100–200 m osmol /l , and at low flows it was 1,400–1,800 m osmol Vasopressin produced urine between 500 and 1,700 m osmol /l always more concentrated than plasma

Lysine vasopressin gave identical results Although vasopressin does not produce the changes of urine flow found in a hot environment, it could contribute to the sodium excretion which can occur in such circumstances At both high and low rates of urine flow, vasopressin increased glomerular filtration (measured by creatinine clearance) so that differences in renal dynamics do not account for the phenomena It appears that the effect of the polypeptide is on electrolyte movements (mainly potassium) in the tubule.

Infusion of adrenaline at a rate of 15 µgm./min. into sheep with urine flows of 0 4–1 ml /min (Fig. 1b) led to excretion of 3–6 ml /min of water with no increase of electrolyte output In partially dehydrated animals there was little effect on water flow Noradrenaline infused at a rate of 5 µgm./min. increased water, sodium and potassium excretion. The effect of adrenaline in increasing water excretion. is the opposite of that found during dehydration Aldosterone increased the re-absorption of sodium in sheep given salt supplements (Fig. 1c) but it did not increase potassium excretion as in carnivores or man[2] There was no change in pH and little in water output under the influence of an infusion of 10–300 µgm d,l-aldosterone in the course of an hour.

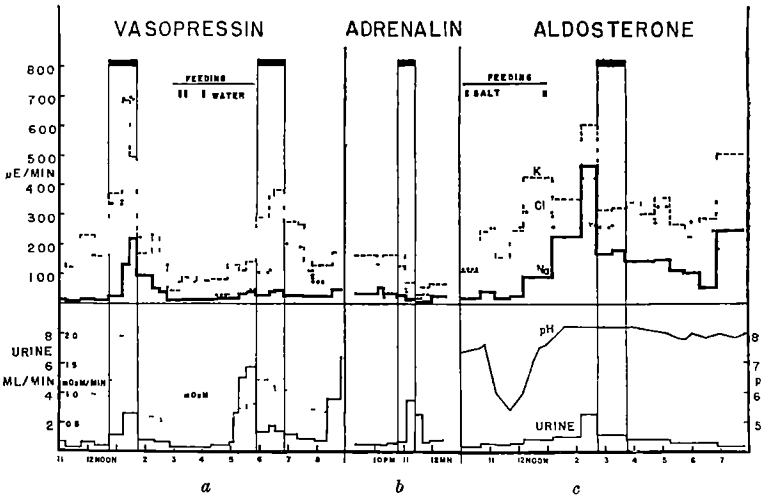

Fig 1 Infusion of hormones intravenously in sheep resulted in urine excretory changes those for potassium, chlorine and sodium being shown in the upper panel while water and osmolar excretion are shown below *a*, Lysine vasopressin (12 milliunits/min) increased low urine flow and decreased high urine flow, but osmolar and electrolyte flow increased in both *b*, Adrenalin (15 µgm /min) caused water to be excreted, but electrolytes were lost at a slower rate *c*, During feeding, urine pH fell, but rapidly returned to the normal 8 2–8 5 Ingestion of sodium chloride in 2-gm aliquots increased sodium excretion and this was reversed for 4 hr by 0 5 µgm /min d,l-aldosterone Excretion of potassium was not increased by this substance

The sheep is thus different from most laboratory animals and man[3] in having a large acid shift of its urine during feeding, in increasing the excretion of salts and water during the action of vasopressin, and in showing no increased potassium excretion under the influence of aldosterone

We are indebted to the Wool Trust Fund and the Rural Credits Development Fund of the Commonwealth Bank for support in this work, to the Ciba Laboratories for the supply of aldosterone, and to Sandoz Laboratories for lysine vasopressin

Paradoxical Effect of Phlorizin on Glucose Uptake and Intracellular Accumulation of Amino-Acids in Rat Kidney Slices *in vitro*

THE discovery by von Mering[1] that phlorizin causes glycosuria in the dog and the observation that phlorizin prevents renal tubular re-absorption of glucose[2,3] have evoked considerable interest in this substance as a tool in the investigation of cellular transport mechanisms Much work with phlorizin has shown this drug to be a potent inhibitor of penetration of hexoses and other sugars in gut preparations[4,5], kidney slices[6], ascites tumour cells[7], and red cells[8] Significant alteration of intracellular metabolism has also been noted This literature has recently been reviewed by Lotspeich[9] and Crane[10]

We have reported[11] that rat kidney cortex slices possess an active transport system for the intracellular accumulation of amino-acids against a concentration gradient This system is dependent on oxidative metabolism as shown by the inhibition produced by anaerobiosis and dinitrophenol In view of the known inhibition by phlorizin of sugar penetration and re-absorption in the kidney, experiments were carried out to ascertain whether this drug similarly affected the penetration of amino-acids into kidney cells This communication demonstrates the unexpected finding that, in contrast to the inhibition of glucose uptake, phlorizin increases the intracellular concentration of amino-acids

Renal cortical slices from male Sprague–Dawley rats were cut with a Stadie Riggs microtome Following a 10-min pre-incubation at 25° C in isotonic Krebs–Ringer bicarbonate buffer, the slices (about 100 mgm /flask) were transferred to 25-ml Erlenmeyer flasks containing the amino-acids labelled with carbon-14 in 2 ml Krebs–Ringer bicarbonate buffer *p*H 7 4 The flasks were gassed with 95 per cent oxygen, 5 per cent carbon dioxide, sealed and incubated in a Dubnoff metabolic shaker at 37° C At the end of the incubation period the slices were dipped in isotonic saline, blotted, weighed on a torsion balance and placed in 2 ml of boiling distilled water for 5 min Aliquots of the incubation medium and the aqueous tissue supernatant were then counted in a liquid scintillation spectrometer, and the ratio of c p m per ml intracellular fluid to c p m per ml extracellular fluid calculated Extracellular space was estimated using inulin labelled with carbon-14 Glucose disappearance from the medium was assayed with glucose oxidase

The results of these experiments are shown in Table 1 Glucose uptake was reduced at phlorizin concentrations of 5×10^{-4} *M* and higher, reaching a 50 per cent reduction at 3×10^{-3} *M* The ratio of intracellular to extracellular amino-acid concentration, however was increased for all the amino-acids studied The increase was most pronounced at the highest phlorizin concentration employed, the intracellular concentration of α-amino-isobutyric acid (AIB) being increased by 77 per cent at 3×10^{-3} *M* The magnitude of the effect on basic amino-acids was somewhat less than that seen with neutral ones For AIB the increase in this ratio was observed at the same concentration of the drug which was noted to block glucose uptake Although the fact that the divergent effects on glucose and amino-acids occur in the same concentration-range suggests the two effects may be inter-related, the amino-acid effect is independent of the presence of glucose in the medium

Table 1 EFFECT OF PHLORIZIN ON GLUCOSE UPTAKE AND INTRACELLULAR CONCENTRATION OF AMINO-ACIDS BY RAT KIDNEY SLICES THE 90-MIN INCUBATION WAS CARRIED OUT IN TRIPLICATE

		Ratio of intracellular to extracellular amino-acid concentration				
Phlorizin* concentration (*M*)	Glucose† uptake (γ/100 mgm)	AIB‡	Glycine	L-Phenylalanine	L-Lysine	L-Histidine
None	258	3 49	5 76	1 85	3 52	2 28
10^{-5}	247					
5×10^{-5}		3 99				
10^{-4}	230	3 89				
5×10^{-4}	157	4 71				
10^{-3}	143	5 09	7 53	2 20		2 61
3×10^{-3}	129	6 18	9 49	3 42	4 55	3 41

* Phlorizin (Mann Co) was twice recrystallized
† Initial glucose concentration, 1 mgm /ml. (5 6 m*M*)
‡ Initial amino-acid concentrations ranged from 0 05 to 0 17 m*M*

In contrast to the kidney slices, experiments with isolated rat diaphragm have demonstrated a slight reduction in the intra-cellular concentration of AIB at 3×10^{-3} *M* phlorizin This has been reported by others[12] Thus, increased intracellular amino-acid concentration as a result of phlorizin action is not a common property of all tissues

Various components of the phlorizin molecule, the aglycone, phloretin, and phloroglucinol were also studied in order to see if the complete glycoside was needed to produce the effect on amino-acids Neither phloretin nor phloroglucinol produced a similar increase in intracellular amino-acid concentration Phloretin is known to be weakly active in inhibiting tubular reabsorption of glucose[13] The complete glycoside appears to be necessary for both the glucose and the amino-acid effect

The mechanism of action of phlorizin-induced inhibition of sugar penetration into cells is unknown although the general view is that the drug affects membrane permeability independently of the observed inhibitory effects on oxidative metabolism[14] as well as various enzymes[10] The explanation for the amino-acid effect is unknown Since these results are seen with a non-utilizable amino-acid (AIB), the phenomena cannot be related to inhibition of amino-acid metabolism *per se* The intracellular concentration of the amino-acid is an equilibrium between influx and efflux rates Phlorizin may produce the observed increased intracellular amino-acid concentration either by augmenting the transport-rate of amino-acids into, or by inhibiting the transport rate out of, the cell. Phlorizin is known to inhibit the tubular excretion of organic acids[15], perhaps indicating a selective effect on amino-acid efflux-rates. However, an induced binding of amino-acids within the cell must also be considered as an explanation. The possible basis for the observed phenomenon is under investigation.

Heart-rates and the Sub-lingual Temperatures of Heat-acclimatized People

PEOPLE resident at sea-level in the equatorial tropics are considered to be 'naturally' acclimatized to heat[1]. There is evidence that the indigenous peoples of these regions have low forearm blood flows and systolic blood pressures in relation to their surface and deep-body temperatures[2-4]. This evidence seems to indicate that the cardiovascular systems of heat-acclimatized people are relatively insensitive to increases of body temperature. If this is true, the relationship between the heart-rates and sub-lingual temperatures of tropical people would be expected to differ from that of people who are not acclimatized to heat. The relationship between the heart-rates and sub-lingual temperatures of young English subjects, at rest in a temperate climate, has been investigated by Tanner[5]. Comparable data are not available for the indigenous peoples of the tropics.

In order to provide these data, measurements of heart-rates and sub-lingual temperatures have been made on thirty-two male Asian subjects in Singapore. The subjects were twenty-two Chinese, eight Indians and two Malays; their average age was 22.7 yr. (*S.D.* = ± 3.1) and their mean body-weight was 57.3 kgm. (*S.D.* = ± 7.2). Each subject wore his normal clothing[4] and lay on his back for 90 min. before any measurements were made. Heart-rates and sub-lingual temperatures were measured every 5 min. for 30 min. and the average of readings for each subject was taken. The mean environmental temperatures during all experiments were 28.9 ± 1.0° C., dry bulb and 25.6 ± 0.9° C., wet bulb. Heart-rates were counted from electrocardiograms and sub-lingual temperatures were measured by means of a 40 s.w.g. copper-constantan thermocouple.

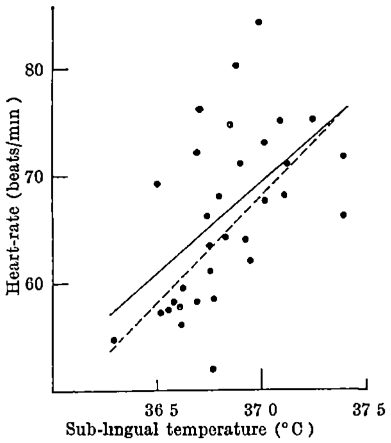

Fig. 1. Heart-rates and sub-lingual temperatures of 32 Asian subjects in Singapore. The continuous line is the fitted regression of heart-rate on sub-lingual temperature for these data. The broken line is the regression of heart-rate on sub-lingual temperature for English subjects, calculated from data presented by Tanner (ref. 6)

The heart-rates and sub-lingual temperatures of the thirty-two subjects are shown in Fig. 1. The correlation coefficient between heart-rate and sub-lingual temperature was 0.554 (0.01 > *P* > 0.001). The equation for the regression of heart-rate on sub-lingual temperature was

Heart-rate (beats/min.) = (17.24 × sub-lingual temperature in ° C.) − 569.19

Also included in Fig. 1 is the regression line for heart-rate on sub-lingual temperature calculated from data presented by Tanner[6]. Tanner's data were obtained from forty-six English subjects whose mean age was 22.1 ± 4.1 yr.; measurements of heart-rates and sub-lingual temperatures on these subjects were made while they lay on a couch at a room temperature of 17.5–20.0° C. The correlation coefficient between heart-rate and sub-lingual temperature in the forty-six subjects was 0.510 (*P* < 0.001) and the equation for the regression line of heart-rate on sub-lingual temperature was

Heart-rate (beats/min.) = (19.54 × sub-lingual temperature in ° C.) − 655.10

The heart-rates and sub-lingual temperatures of the heat-acclimatized people in Singapore tended to be higher than those of Tanner's subjects in England. The slope of the regression line of heart-rate on sub-lingual temperature was slightly greater for the English subjects. However, the correlation and regression coefficients for the two groups of data were not significantly different (*P* > 0.10).

These results have not provided any evidence that acclimatization to heat is associated with a significant general variation in the sensitivity to temperature of the tissues of the cardiovascular system. The possibility remains that changes of sensitivity to temperature are localized in discrete areas of the body such as the forearm blood vessels or centres in the brain. The latter possibility would be in agreement with a previous suggestion that acclimatization to heat involves adaptive changes in the central nervous system[7].

BIOPHYSICS

Elimination of the Liquid Junction by using Glass Electrodes

It is assumed in measuring potential with hydrogen or alkali-sensitive glass electrodes[1] that the salt bridge which connects the reference electrode to the solution generates a negligibly small potential at the liquid junction. This is a reasonable assumption so long as the unknown solution contains no colloids, and its ionic strength is approximately that of the buffers used in standardization. Unfortunately these ideal conditions are seldom met in biological systems. The resultant error is often of a serious magnitude, as shown in experiments on *p*H in colloidal systems[2,3].

In many inorganic systems the liquid junction potential has been eliminated by the use of silver–silver chloride and other metallic reference electrodes placed directly into the unknown solution without a salt bridge[4]. The metallic reference electrodes function poorly in most biological systems because of the various interfering oxidizing and reducing substances which are present.

Glass electrodes are not affected by oxidation-reduction reactions and are well suited for use in biological media. With these advantages in mind, a system was designed and tested in which a hydrogen-sensitive glass electrode functioned as a reference electrode for sodium activity measurements with a sodium-sensitive glass electrode. The *p*H of the solution being tested was kept at 7·21. Any error in sodium determination which might have occurred if the *p*H were allowed to shift would tend to be automatically balanced out because the sodium-sensitive glass is also sensitive to hydrogen ions. The sodium concentration was varied by addition of 1 *N* sodium chloride to the buffer solution (*tris*-hydroxymethylamminomethane buffer[5]).

The sodium-sensitive glass electrode was of the bulb type (Electronic Instruments, Ltd., glass *BH* 104) while Corning 015 glass was fused to a lead glass stem to form the hydrogen-sensitive MacInnes–Dole type electrode. All potentials were measured with the Vibron model 33*B* electrometer and model *C*33*B* 'bucking' circuit.

Hydrogen ion sensitivity of the Corning 015 glass electrode was checked with buffers from the National Bureau of Standards (from *p*H 4·65 to 9·18), using a saturated potassium chloride–calomel reference electrode. The liquid junction between the saturated potassium chloride and buffer being tested was made through a porous ceramic plug. The sodium ion sensitivity of the *BH* 104 glass was tested in a *tris* buffer solution (*p*H 7·21) by varying the concentration of sodium with 1 *N* sodium chloride. The reference electrode was again the saturated potassium chloride–calomel with a porous ceramic plug. Representative data (circles) for the sodium-sensitive glass electrode and calomel reference are shown in Fig. 1. The hydrogen ion-sensitive glass electrode was then substituted for the calomel reference and the sodium ion measurements repeated in the *tris* buffer solutions (triangles in Fig. 1).

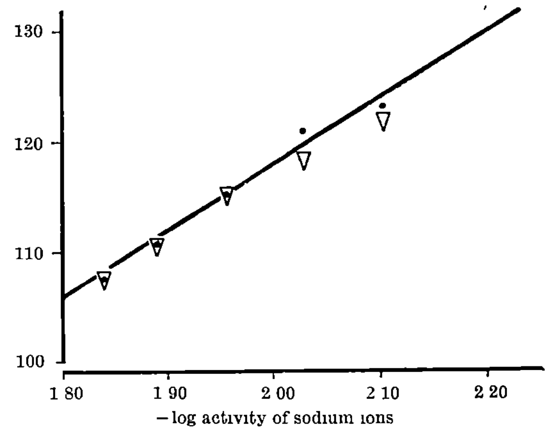

Fig. 1. Representative sodium-sensitive glass electrode potentials (circle) using a calomel reference electrode and (triangle) using a Corning 015 MacInnes–Dole glass electrode as the reference electrode. The straight line plots the slope of the theoretical potential given by the Nernst equation $E = E^0 + 2{\cdot}303RT/F$ (log a_{Na^+}) while the points are experimental measurements. The value of 2·303*RT*/*F* was taken as 59 mV at 23° C. The negative logarithm of the activity of Na^+ is plotted on the abscissa using an activity coefficient of 0·73 based on the presence of a constant 0·2 *M* buffer solution.

The equivalent response of the sodium ion electrode with either the standard saturated potassium chloride–calomel reference or the Corning 015 glass reference illustrates the ability of the glass electrodes to function in a system as both an ion-specific electrode and reference electrode. The simplicity of this method of eliminating the liquid function should prove useful to workers in many fields, especially when the specific cation to be measured is a solute in a complex solution.

This work was aided by U.S. Public Health Service research training grant No. *HTS* 5454.

Mechanism of Nicotinic Action at the Adrenal Medulla: Calcium as a Link in Stimulus-secretion Coupling

In experiments to probe the mechanism of transmission of sympathetic activity at the adrenal medulla we have found that acetylcholine, which is believed to be the chemical transmitter, evokes catecholamine secretion through some calcium-dependent process. Our evidence, obtained in experiments in cats' adrenal glands perfused *in vivo* or *in vitro* with Locke's solution or variations of it, may be summarized as follows

Acetylcholine failed to release catecholamines when calcium was omitted from the perfusion fluid (in similar experiments in which sodium or potassium was omitted acetylcholine still had a strong stimulant effect) The amount of catecholamines released by acetylcholine varied with the calcium concentration of the perfusion fluid over a wide range, being increased about 50 per cent above the normal with 8 8 m*M* calcium and being about doubled with 17 6 m*M* calcium Calcium itself (2 m*M*) following a period of calcium-free perfusion caused a vigorous secretion of catecholamines This evidence, considered along with the known ability of acetylcholine to increase membrane permeability at other junctional sites, led us to postulate that acetylcholine evokes secretion of catecholamines by causing an influx of calcium ions into the adrenal medullary cells[1]

In support of this postulate, one of us (W W D) has recently found in experiments with Dr A M Poisner that acetylcholine (10^{-5} gm /ml) greatly increases the uptake of calcium-45 by the adrenal medulla We have in fact proposed that calcium has a role in the process we have termed 'stimulus-secretion coupling' analogous to its supposed role in 'excitation-contraction coupling' in muscles A full account of these experiments will be published elsewhere[2]

We have now obtained evidence that other substances which stimulate the adrenal medulla and which belong to the family of drugs with 'nicotinic' actions evoke secretion in a similar fashion The present experiments were carried out on cat's adrenal glands acutely denervated and perfused *in situ* through the aorta with Locke's solution In such experiments the 'resting' secretion of catecholamines appearing in the effluent collected from the adrenal veins was usually equivalent to about 50–100 mμgm adrenaline (base)/min The addition of 10^{-5} gm / ml nicotine, tetramethylammonium, lobeline or dimethyl-4-phenylpiperazinium iodide (DMPP) to the perfusion fluid caused an enormous increase in the catecholamine output Not uncommonly the secretion evoked by these drugs, particularly DMPP and nicotine (which seemed to be especially active), was more than 100 times the control 'resting' secretion

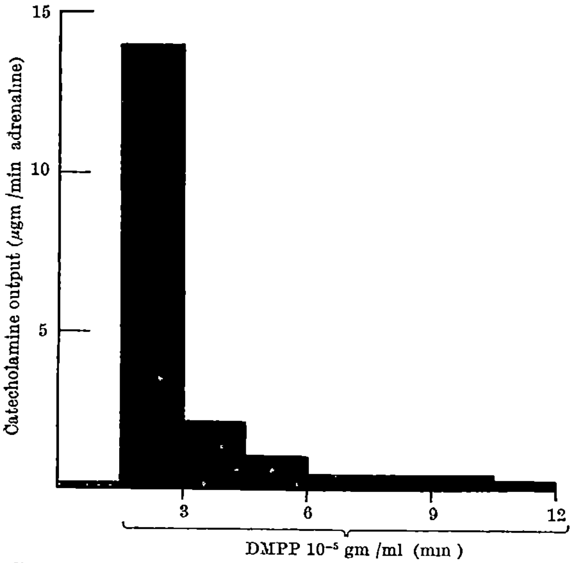

Fig 1 A typical secretory response of perfused cat's adrenals to DMPP 10^{-5} gm /ml Both adrenals were perfused with Locke's solution and the effluent assayed in terms of adrenaline (base) by bioassay with the spirally cut rabbit aorta Before addition of DMPP the gland was perfused for 20 min during which the 'resting' output was determined the output in the last 1½ min of this period is indicated

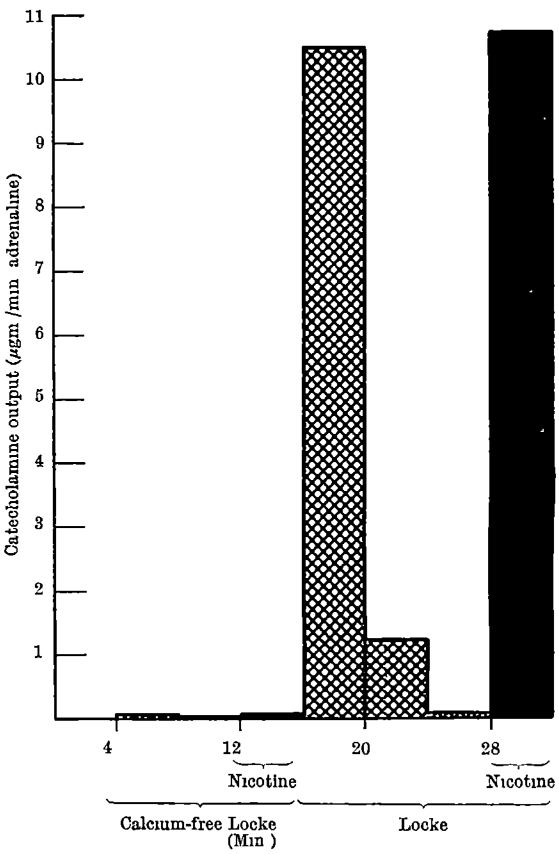

Fig 2 Failure of nicotine (10^{-5} gm /ml) to evoke catecholamine secretion in the absence of calcium The thickening of the baseline to the left indicates the 'resting' outputs (min 4–12) and the negligible response to nicotine (min 12–16) in calcium-free Locke's solution The cross-hatched bars which follow indicate the stimulant effect of re-introducing calcium (in the form of Locke's solution) The solid bar to the right indicates the control response to nicotine in Locke's solution

A typical response is shown in Fig 1, from which it can be seen that DMPP increased the rate of secretion to more than 13 μgm /min This high rate of secretion was not maintained, but fell progressively so that in about 10 min it was near to the resting value despite the continued presence of the drug The cause of this progressive diminution in the response was not determined for the present purpose tests were made with each of these substances by perfusing them in this same concentration (10^{-5} gm / ml) for periods of 4 min. In each experiment one or the other drug was first tested in Locke's solution free of calcium and then in Locke's solution. In each instance the drugs were active in Locke's solution but inactive (or almost so) in calcium-free Locke's solution A typical experiment is shown in Fig 2 After a period of perfusion with calcium-free Locke's solution (usually 16 min) perfusion was switched to calcium-free Locke's solution with the addition of nicotine (10^{-5} gm /ml) This raised secretion very little, if at all, above the resting value Perfusion was then switched back to Locke's solution This change in itself caused a transient but very vigorous secretion which, as mentioned above, is due to the re-introduction of calcium (it occurs also without prior exposure to any of the stimulant drugs) When spontaneous secretion had returned to a low level perfusion was once more switched, this time to Locke's solution plus nicotine Nicotine then exerted its familiar powerful excitant effect raising secretion to more than 10 µgm /min Similar results were obtained with TMA, lobeline and DMPP

It thus appears that these various drugs of the 'nicotine group' may all evoke catecholamine secretion by causing calcium ions to penetrate the medullary cells

PHARMACOLOGY

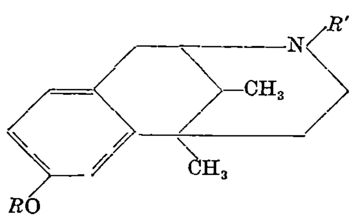
A New Potent Analgetic Antagonist

The discovery of a new potent analgetic with a reduced liability to addiction[1] in the benzomorphan series, namely, 2′-hydroxy-5,9-dimethyl-2-phenylethyl-6,7-benzomorphan[2] (I), has suggested further work in the series 2′-Hydroxy-5,9-dimethyl-2-allyl-6,7-benzomorphan (III) is a potent antagonist of phenazocine, morphine, meperidine, and other analgetic agents This compound is of special interest in that combinations of phenazocine and III in ratios of 5 1 to 100 1 retain analgetic activity in animals yet seem to be relatively devoid of physical dependence properties in the monkey in both acute and chronic experiments (biological details of this work will be described elsewhere)

The demethylation of 2′-hydroxy-2,5,9-trimethyl-6,7-benzomorphan has been described[2] Reaction of the nor-compound (II) with a slight excess of allyl bromide in ethanol containing sodium bicarbonate for 18 hr under reflux gave, after filtration, concentration and trituration with ether, the product (III), m p 141–144° in 46 5 per cent yield Anal calc $C_{17}H_{23}NO$, C, 79 33, H, 9 01, N, 5 44 Found C, 79 06, 78 99, H, 9 19, 9 29, N, 5 64, 5 78

A mixture of 5,9-dimethyl-2′-methoxy-6,7-benzomorphan (IV), prepared by treating 5,9-dimethyl-2′-hydroxy-6,7-benzomorphan[2] (II) in ethanol with diazomethane in ethanol containing sodium bicarbonate was treated with allyl bromide under reflux After appropriate working up, the residue was dissolved in acetone and treated with ether to give the desired product (V), m p 216–218°, for the hydrochloride salt Anal calc for $C_{18}H_{25}NO$ HCl C, 70 22; H, 8 51, N, 4 55 Found C, 70 00, H, 8 50, N, 4 78

The present antagonist (III) combined with phenazocine in a 1 1 ratio showed no analgesia, and precipitated abstinence phenomena in the morphine-addicted monkey (Deneau, G A, and Seevers, M H, private communication) With a ratio of 9 parts of phenazocine to 1 of the antagonist (III), the analgesic effect was as good as with phenazocine alone, and there was a precipitation of abstinence in addicted monkeys as seen with nalorphine, instead of a suppression Mixtures of 25 : 1 and 50 1 acted similarly, with a 100 1 mixture there was no precipitation of abstinence and no suppression up to a dose of 16 mgm /kgm The retention of good analgesic effect without suppression of abstinence, indeed with the presence of nalorphine-like effects with respect to precipitation of abstinence in morphine-addicted animals, seems very promising and these mixtures will be studied in man The antagonist (III) itself showed no significant analgesic effect in animals



I $R=H, R'=CH_2CH_2C_6H_5$

II $R=H, R'=H$

III $R=H, R'=CH_2{-}CH=CH_2$

IV $R=CH_3, R'=H$

V $R=CH_3, R'=CH_2CH=CH_2$

An analgesic effect of nalorphine in man, and retention of the analgesic effect of morphine in appropriate mixtures of morphine and this antagonist, were first reported by Beecher and Lasagna[3] Later it was shown that morphine–nalorphine mixtures administered repeatedly to former addicts (Fraser, H F, and Isbell, H, personal communication) produced a milder degree of physical dependence than equivalent doses of morphine alone N B. Eddy, M Piller, L A Pirk, O Schrappe and S Wenda[4] have shown that when mixtures of morphine and levallorphan (an antagonist of the morphinan group) were administered for chronic pain there was a definite trend toward delay in the development of tolerance and physical dependence under clinical conditions

Anti-Asthmatic Effect of Phenazone and Amidopyrine

Many chronic asthmatics state that they obtain relief from proprietary asthma powders available in Germany without medical prescription Most of these powders contain either phenazone or amidopyrine, besides much smaller quantities of various other ingredients In the list of German proprietaries (the "Red List"), we have found 53 such preparations, of which 27 contained phenazone, 22 amidopyrine and 4 both

As little seems to be known about the anti-asthmatic effects of phenazone and amidopyrine, we have investigated the question in 46 patients with chronic asthma, who were trained in spirometry In each experiment the patient's vital capacity was recorded successively three or more times, and he was then given placebo or drug by mouth 1 hr later a second series of vital capacities was recorded as before The

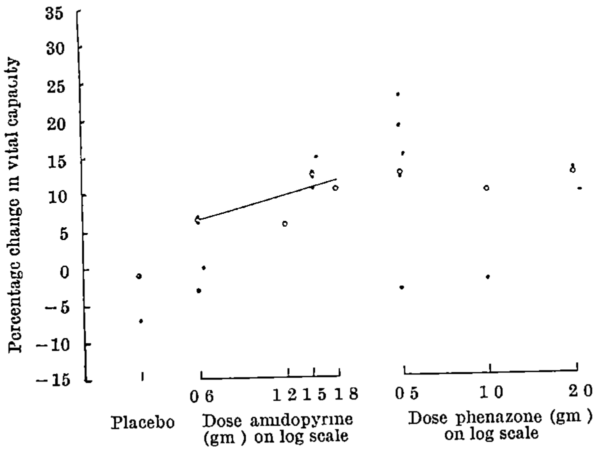

Fig. 1. Percentage change in vital capacity for placebo and doses of amidopyrine and phenazone. ●, Individual experiments; ○, mean response at each dose

means of vital capacities before and after treatment were calculated and results expressed as percentage change of vital capacity. On some occasions we also recorded peak flow and forced expiratory volume, but recording the latter tended to increase bronchial spasm.

Twenty-seven patients received phenazone in doses of 0·5, 1·0 or 2·0 gm. in 63 experiments, and 26 patients received amidopyrine in doses of 0·6, 1·2, 1·5 or 1·8 gm. in 43 experiments. Placebo was given in 17 experiments. The percentage changes in mean vital capacity from the basal values before treatment in each experiment and the overall mean values after placebo and at each dose of drug are plotted in Fig. 1. A representative example of the phenazone effect is given in Fig. 2.

Compared with the basal values before treatment, the increases in vital capacity after amidopyrine or phenazone are evident from Fig. 1, while the change after placebo is negligible. The differences between placebo and all doses of phenazone or of amidopyrine are highly significant ($P < 0{\cdot}001$ in both cases).

The calculated regression line for amidopyrine, which has significant slope ($P < 0{\cdot}05$), is also given in Fig. 1. A regression line was not calculated for phenazone, because it clearly would not have a significant slope. Where forced expiratory volume was recorded we found no definite effect, but the peak flow usually increased when the vital capacity increased.

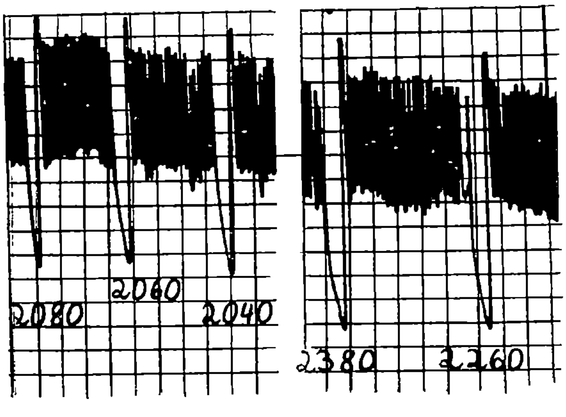

Fig. 2. Effect of phenazone on vital capacity of a chronic asthmatic. Left-hand panel, before treatment; right-hand panel, 1 hr. after phenazone, 2·0 gm. by mouth. The figures give the vital capacities in ml.

These results show that phenazone and amidopyrine lessen respiratory obstruction in most chronic asthma patients examined. Results with aspirin, so far unpublished, have been comparable. Our experience with other agents, such as histamine and isoprenaline, has shown that an increase or decrease of vital capacity by less than 4 or 5 per cent remains subjectively unnoticed, but greater changes are felt by the patient. Since most increases of vital capacity exceeded 5 per cent after all doses of both drugs, most patients felt relief from phenazone and amidopyrine, as was to be expected.

A search in the literature has so far revealed no previous reference to the anti-asthmatic action of amidopyrine. Two reports, one of 1889[1] and one of 1890[2], have been found on phenazone. In each of these the drug was claimed to have relieved asthma in one patient. Our results indicate that in many asthma cases both drugs play a more active part than was hitherto supposed.

The anti-asthmatic action of phenazone, amidopyrine and aspirin, which also inhibit histamine release in anaphylaxis[3], is particularly interesting because these drugs specifically antagonize bradykinin broncho-constriction in the guinea pig[4,5], and because inhalation of bradykinin aerosol reduces the vital capacity of chronic asthmatics[6]. We are therefore investigating the possible relationship between bradykinin and asthma; but in 30 experiments in which one of these analgesic-antipyretic drugs was given orally before the patient inhaled a bradykinin aerosol, the reduction of vital capacity by bradykinin was inhibited on only seven occasions. This result points against the antagonistic effect of these drugs to bradykinin in man, but work on this problem continues. Results will be published in detail later.

PATHOLOGY

A New Method for Local Chemical Analysis of Human Tissue

As a consequence of the original work of Castaing[1] on the electron beam micro-analyser, widespread application has been made in the field of physical metallurgy[2]. It is the purpose of the present communication to record the applicability of this technique to biological problems. In the Castaing instrument a beam of electrons, focused to a spot 1μ in diameter, excites fluorescent or secondary X-rays in the specimen, which are analysed in a crystal spectrometer with Geiger counter detection. An optical microscope with a reflecting objective permits simultaneous viewing and analysis of the

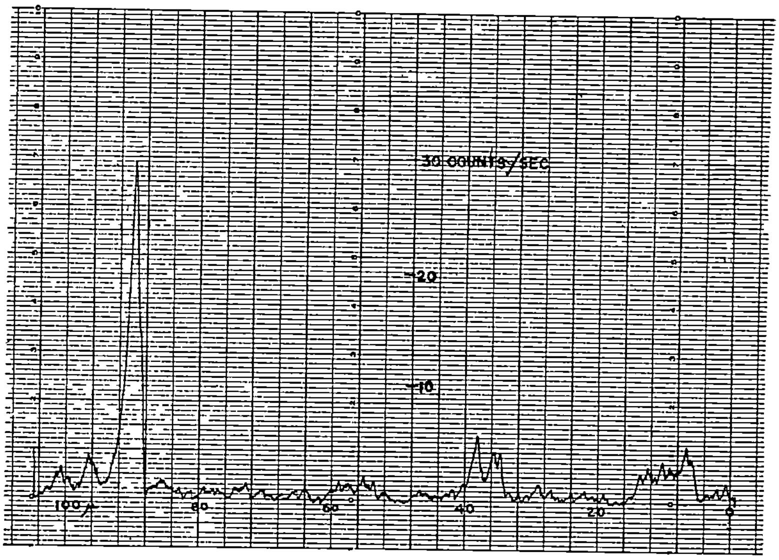

Fig 1 Iron distribution in a synovial membrane

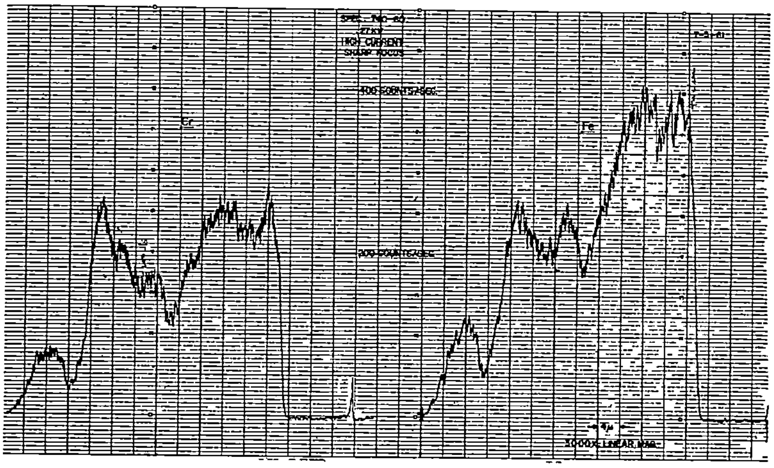

Fig 2 Iron and chromium distribution in joint capsule (hip joint prosthesis)

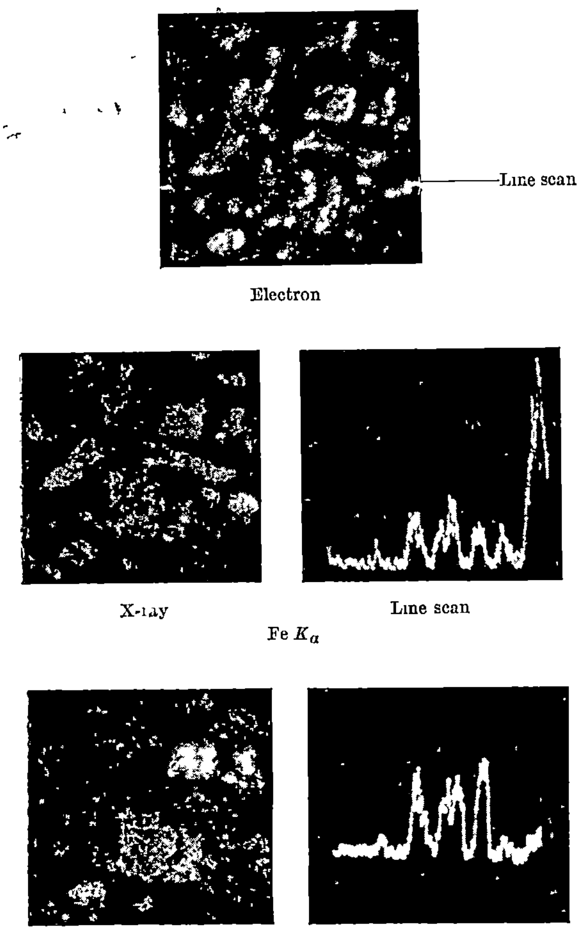
irradiated spot Mechanical stage motion allows the selection for analysis of any desired spot in the specimen The range of elements at present detectable coincides with that of modern X-ray spectrographs, that is, elements lying above sodium in the Periodic Table Two characteristics of these instruments of paramount importance to biological research are (1) a detectable limit as low as 10^{-14} gm , (2) spatial resolution of approximately 1μ Birks has recently discussed the electron probe instrument in its numerous modifications[3]

In solids which are good conductors of heat and electricity, electron bombardment in the instrument produces no damage In biological materials, however, damage to a specimen may be catastrophic under irradiation by 25-kV electrons at current densities of the order of 100 amp /cm ^{2}. Our experiments have been made on microtome sections of tissue nominally 4μ thick, mounted on polished carbon rods Sections were cut from formalin-fixed paraffin blocks, and picked up from distilled water with the carbon rods Subsequent dehydration and removal of paraffin with organic solvents was accomplished, producing a specimen of tissue firmly bonded to the underlying carbon These were analysed without further manipulation in the electron probe instrument manufactured by the Paris firm of CAMECA Although produced by techniques standard in pathology, the specimens proved to be virtually indestructible

Fig 1 shows the results of an iron analysis in human synovial membrane, pathologically diagnosed as pigmented villonodular synovitis The curve is a typical linear scan across the specimen, showing the intensity of iron K_a X-rays as a function of position Beam current was 2×10^{-8} amp at an accelerating potential of 27 kV Sharp beam focusing is indicated by the steepness of the response curves Maximum X-ray intensity observed in Fig 1 is some 30 counts/s , under identical instrument conditions a solid iron specimen emits 700 c p s Under much higher beam currents this specimen of tissue was found to yield intensities from iron-rich regions as high as 800 c p s , with a spot diameter about twice as large as that used in obtaining Fig 1 Therefore it may be estimated that the minimum detectable amount of iron in a spot of 4μ diameter is about one-thousandth of that actually present in this section of tissue

An example of exogenous material present in tissue is furnished by the curves of Fig 2 This material is a section of joint capsule taken from the vicinity of a surgical metallic implantation (hip joint prosthesis) Two linear scans show the distribution of iron and chromium along the same path The remarkable similarity of these curves implies the co-precipitation of these two elements in this particular region of the tissue Noteworthy is the low background, essentially zero, and the steepness of rise at the edge of the metal-rich areas It was observed further that sequential beam traverses over the same path gave practically identical responses, that is, for analytical purposes the method is non-destructive under the instrumental conditions used (27 kV, 10^{-7} amp , beam scanning speed, 12 μ/min)

The same specimen was investigated in a scanning probe which utilizes the 'flying spot' arrangement of Cosslett[4] In this instrument the electron beam is caused to execute two-dimensional scanning while the emitted X-rays are used to modulate the intensity of a synchronously driven cathode-ray tube Photography of the cathode tube display yields a television-like image of the distribution of a chosen element Alternatively, an image formed by back-scattered electrons may be displayed, giving information analogous to the conventional image formed by an optical microscope Fig 3 shows the same specimen as Fig 2, imaged successively by means of scattered electrons, iron K_a, and chromium K_a X-rays Identical areas at a magnification of 300 are covered by the three images Also shown are two linear



Electron

X-ray Line scan

Fe K_α

X-ray Line scan

Cr K_α

Fig 3 Same specimen as Fig 2, imaged by back-scattered electrons, iron and chromium X-rays

scans similar to those of Fig 2, plotting variations in iron and chromium concentrations across the tissue Fig 3 clearly indicates differing composition from one metal-rich area to another in this tissue No serious damage to the specimen occurred during the experiments, and the pictures of metallic localizations in Fig 3 were reproducible

It appears that the Castaing electron probe microanalyser is directly applicable to the field of human pathology With proper specimen preparation, the microtome section is amenable to extremely sensitive chemical analysis Many problems in cellular chemistry and pathology could be investigated by the use of the technique For example, preliminary investigation has shown the feasibility of measuring the distribution of calcium and phosphorus in undecalcified bone blocks

We wish to acknowledge with thanks the support and encouragement of F L LaQue, and the help of Carl Kruse, Cambridge Instrument Co , in the use of the beam scanning probe

Note added in proof An oral presentation in this subject was made on November 15, 1961, at the Eastern Analytical Symposium, New York City, entitled "Elemental Analysis (Cu, Ag Fe) at the Subcellular Level in Tissue Sections of Human Specimens by Means of the Electron Microprobe", by A J Tousimis, George Washington University, and I Adler, U S Geological Survey

Carcinogenicity of Dibenzo(a,l)pyrene

DIBENZO(*a*,l)PYRENE (1,2,3,4-dibenzopyrene) has been shown to be present in cigarette smoke condensate and in automobile exhaust gas in small quantities[1–5] In view of this, the relative dearth of tests for the carcinogenic activity of this substance is surprising Though dibenzo(*a*,l)pyrene was regarded as a strong carcinogen by Cook and Kennaway[6] and by Pullman and Pullman[7], the only biological evidence we could find in the literature has been presented by Bachmann *et al* [8] These authors placed a 0 3 per cent dibenzo(*a*,l)pyrene solution in benzene on two mice After 6 months one mouse died The remaining mouse lived for 262 days and had developed an epithelioma To our knowledge no other group of workers has reported the carcinogenic activity of dibenzo(*a*,l)pyrene[9]

This report presents results of testing the carcinogenic activity of different concentrations of dibenzo(*a*,l)pyrene With slight modifications in the method, dibenzo(*a*,l)pyrene was synthesized by Zander's method[10] The material used for testing was purified by vacuum-sublimation, repeated column chromatography on alumina and recrystallization from benzene. The purity of this hydrocarbon (m p 224–226° C) was checked by ultra-violet absorption and fluorescence spectra and by paper chromatography[1]

Acetone solutions in concentrations of 0 25, 0 1, 0 05 and 0 01 per cent were applied thrice weekly to the backs of 6-week-old Swiss (Millerton) female mice The materials were applied with one stroke of a camel-hair brush (No 5) Re-grown hair was removed with an Otis clipper whenever necessary

RADIOBIOLOGY

Production of Chromatid Aberrations by Diepoxybutane and an Iron Chelator

RECENT investigations have shown that chromatid breaks produced by certain radiomimetic agents in combination do not interact to produce reunions[1]. Specifically, breaks produced by 8-ethoxycaffeine do not form exchanges with those produced by maleic hydrazide, nor do the breaks produced by potassium cyanide and β-propiolactone interact with each other. Conversely, breaks induced by X-rays will interact with those produced by potassium cyanide, β-propiolactone, 8-ethoxycaffeine and maleic hydrazide. The interpretation of these results was stated in terms of differences in the bonds broken by the chemical agents, such differences precluding interaction or rejoining of broken ends of chromosomes.

As part of an investigation of radiomimetic agents and an iron chelator, a series of experiments utilizing combined treatments was performed. In addition, combined treatments with X-rays and 1,2-3,4 diepoxybutane or 2,2′ bipyridine were carried out. The material used consisted of the lateral roots of *Vicia faba* (Carter's Seville Longpod) grown at 20° C. for 7 days prior to treatment. The chemical agents were used as follows: 2,2′ bipyridine, 2×10^{-3} *M* for 15 min.; potassium cyanide, 1×10^{-3} *M* for 30 min.; 1,2–3,4 diepoxybutane, 3×10^{-3} *M* for 15 min. In the X-ray experiments, the roots were exposed to 100 r. X-rays administered in 54 sec. The source used was a 'Keleket 220-*C*' X-ray unit operated at 180 kV.p. and 18 m.amp. with 1·3 mm. aluminium and 0·8 mm. copper filtration. Irradiations were performed by Dr. John E. Edwards, of the Department of Physics, Ohio University. Roots were immersed in 1,2-3,4 diepoxybutane or 2,2′ bipyridine for 13 min. prior to irradiation, exposed while immersed, and rinsed 1–2 min. following exposure. Feulgen squashes were prepared from roots fixed 24 and 48 hr. following treatment.

* A minimum of 200 cells was analysed for each treatment.

The peak effect of combined treatment with potassium cyanide and 1,2-3,4 diepoxybutane occurs in early interphase as indicated in the roots fixed 48 hr. after treatment. This result is consistent with my preliminary investigations. The combined applications of potassium cyanide and 1,2-3,4 diepoxybutane have elicited two unexpected results (Table 1). When the two agents were administered one following the other, in either order, the resultant frequency of exchanges clearly indicated interaction between the breaks produced by the two compounds. The implication is that the breaks produced are of a similar or identical chemical nature. This result is contrary to that found with potassium cyanide and beta-propiolactone[1]. The other unforeseen result arises from the simultaneous treatment with potassium cyanide and 1,2-3,4 diepoxybutane. The aberration frequencies were so high as to make analysis difficult. It is probable that in this case potassium cyanide as a metabolic inhibitor prevents the restitution of broken ends of chromosomes. Thus, all the breaks produced by the two agents are available at the same time and for a longer period of time favouring reunions and deletions. Potassium cyanide is known to inhibit the terminal stages of cellular respiration, and in this way reduces the available energy necessary for restitution[2]. Results of this type were also obtained in *Allium* roots treated with X-rays and carbon monoxide in the dark[3].

The results of the X-ray experiments are presented in Table 2. The frequencies of exchanges and isochromatid deletions produced by treatment with X-rays and 1,2-3,4 diepoxybutane indicate a strictly additive effect. This result is expected for the deletions but not for exchanges. Earlier work has indicated that, for the most part, breaks produced by radiomimetic agents interact with those produced by X-rays[1,4,5]. An explanation of these results may lie in the difference in the peak time of effect of the two agents Early interphase is the most sensitive period with respect to 1,2-3,4 diepoxybutane activity, whereas late interphase appears to be more sensitive to X-ray treatment[6]. Therefore, the majority of breaks produced by the two agents would not be available at the same time to facilitate reunions This argument has been presented previously by Auerbach[4] The additive effect produced by X-rays and 1,2-3,4-diepoxybutane is evident for both 24- and 48-hr recovery despite the fact that 1,2-3,4 diepoxybutane has an appreciable effect in late interphase (Table 2, 24-hr recovery period) This is also the time during which X-rays have their maximum effect Presumably, a large number of broken ends are available at this time for interaction, but interaction does not occur Since X-rays have an essentially random effect in producing chromosome breaks, certain of these breaks must involve bonds similar to those broken by 1,2-3,4 diepoxybutane as well These breaks of similar bonds would be expected to undergo reunions with each other to increase the total yield of exchanges The effect, therefore, cannot be explained in terms of one mechanism, but probably depends on considerations of both a temporal nature and a qualitative difference between the breaks produced by the two agents.

The results of the X-ray investigations with bipyridine (Table 2) are similar to those with 1,2-3,4 diepoxybutane. There is no enhancement of X-ray effect with 2,2′ bipyridine, nor is there any indication of interaction of breaks produced by the two agents The effect is additive for isochromatid deletions and exchanges at both recovery periods The result is in basic agreement with similar work by Kihlman[7] Normally, one would expect at least an additive effect of the two agents for both aberration types In the results reported here, even an additive effect is lacking in most instances This may indicate that the effect of 2,2′ bipyridine is to reduce the total yield of aberrations in some manner The sticky effect and clumping of chromosomes produced by 2,2′ bipyridine may cause a masking of the true breakage frequencies and may account for the apparent lack of an additive effect This aspect of the results requires further investigation before a clear explanation can be presented The absence of interaction between 2,2′ bipyridine and X-ray-induced breaks is again contrary to previous results 2,2′ bipyridine appears to act over a long period during interphase, part of this period coinciding with the time during which the peak effect of X-rays occurs Thus, the presence of breaks at the same time, and the random effect of X-rays, would be expected to permit interaction The mechanisms of breakage by the two agents are possibly different or there may be a qualitative difference in the breaks produced The low frequency of aberrations produced by 2,2′ bipyridine alone further complicates the situation, and the role of 2,2′ bipyridine as a metabolic inhibitor is even more difficult to evaluate from these results

Radioactivity in Wool

KULWICH *et al* recently reported[1] the presence of unidentified γ-ray activity in several samples of wool The bulk of the observed activity in the wool was shown to be most probably associated with its impurities and hence due to natural and fall-out contamination

In May 1960 we examined a sample of wool for its potassium-40 content in conjunction with an experiment for the determination of lean-to-fat ratio *in vivo* by determining the potassium content of the animal Since then, we have again examined two samples of raw wool for their associated radioactivity Each sample consisted of approximately 500 gm of the material, and the work was performed in a low-background room (iron room) of the Biological and Medical Research Division of the Argonne National Laboratory A 5 in × 4 in sodium iodide (thallium) crystal detector was used in conjunction with an Argonne type 256-channel pulse-height analyser

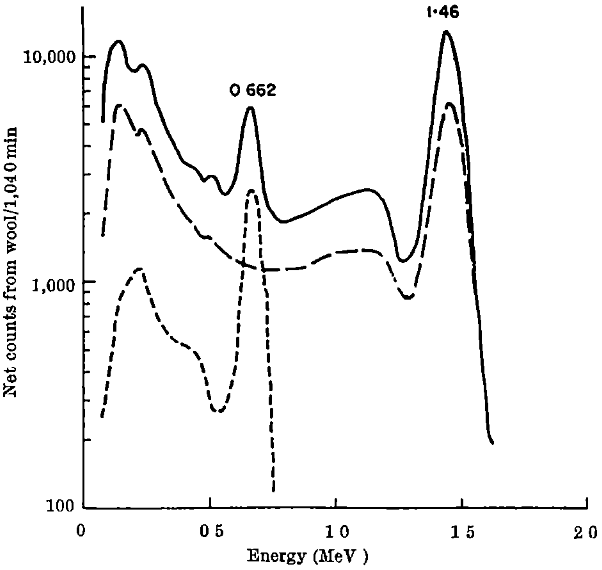

Fig 1 Net γ-ray spectra of raw wool samples (——), compared with spectra for potassium-40 (– – –), and cæsium-137 (- - - - - -) standard

Our work confirms the presence of γ-emitting radionuclides in the wool of Hampshire ewe and Rambouillet ram lambs, and allows tentative identification of the major components of such activity Fig. 1 shows the net γ-ray spectrum of one of the two wool samples as well as γ-ray spectra of potassium-40 and cæsium-137 for comparison The spectra from the two samples of wool are identical in shape but differ in absolute amount of the activity present. Except for trace quantities of other nuclides only two prominent nuclides are observed, namely, potassium-40 and cæsium-137. In practice, the sample to be encountered probably will vary widely in activity, hence our values shown in Table 1 indicate only the order of magnitude to be expected

Since no natural activity aside from that of potassium-40 was observed, one can conclude that the potassium-40 activity is present in wool grease, suint,

Table 1

	Hampshire ewe	Rambouillet ram
gm potassium/kgm wool	32	14
μμc ^{137}Cs/kgm wool	356	438
μμc ^{137}Cs/gm potassium	11	31

and dead skin in the wool[2] Cæsium-137, on the other hand, probably comes from two different sources, namely, from fall-out contamination as well as from the sources present in the wool If an appreciable portion of the activity were due to fall-out contamination, we should observe ruthenium-106 and cerium-144 in larger than trace quantities, hence the major portion of it must be due to the second cause Public Health Service Data[3] of July 1958–July 1960, add some credence to this conclusion For example, the level of cæsium-137 in milk has varied approximately from 15 to 70 μμc /gm potassium during this period and now is running in the range 15–25 The observed values for wool are also in this range

BIOLOGY

Toxicity associated with Certain Samples of Groundnuts

A NEW disease, called 'turkey *X* disease' has been described since the widespread outbreaks of deaths in turkey poults in 1960[1] Post-mortem examination of dead poults from field outbreaks revealed acute hepatic necrosis, associated with generalized bile duct proliferation Siller and Ostler[2] directed attention to the similarities of the lesions to those of *Senecio*-alkaloid poisoning in the fowl described by Campbell[3]

Table 1 COMPOSITION OF DIETS

* *J Nut* , 24, 245 (1942)

In the search for the toxic agent, no contamination with any known insecticide, solvent, plant toxin or alkaloid could be found However, Blount noted that these outbreaks of disease had followed the use of Brazilian groundnut meal in the feed. Some batches of the meal were shown to be toxic for turkeys[1], and for ducklings[4] A toxic fraction has now been isolated and shown to be free from plant alkaloids[4] This toxic material has also been found in some samples of other groundnut meals and groundnuts[5]

While the above investigations were in progress, we observed that feeding Brazilian groundnut meal to newly weaned rats did not produce the acute toxicity seen in turkey poults. However, a few weeks of feeding a diet containing 20 per cent Brazilian groundnut meal reduced growth-rate and food intake, and the continued feeding of this diet caused severe liver lesions. This communication describes the changes seen after a sample of Brazilian groundnut meal known to be toxic to turkey poults had been fed to rats for 6 months.

Three groups (9 male and 7 female) of 4-week-old rats from our inbred colony were caged singly and fed on the following diets purified diet, purified diet with 20 per cent of the starch replaced by Brazilian groundnut meal, and a diet with 20 per cent (control) Indian groundnut meal The purified diet used is our standard purified diet (Table 1)

All rats received tap-water *ad lib* , were weighed weekly and their food intakes measured at twice weekly feeding After 9 weeks, 2 male and 2 female rats from each group were killed for post-mortem The remainder were killed after 30 weeks feeding, by this time the males had eaten 650 gm of groundnut meal.

Histological examinations were carried out as follows Tissues were fixed in formol-saline, embedded in paraffin and sectioned at 7μ (hæmatoxylin and eosin), the liver sections were also stained by Gallegio, reticulin (Gordon and Sweet) and periodic acid–Schiff methods. Frozen sections of the liver and kidney were stained for fat by sudan IV

Growth-rate, food consumption and food conversion ratio were similar in the two control groups receiving the purified diet and the Indian groundnut meal. The weights of rats fed the Brazilian groundnut meal were all lower than the controls, the difference was not significant for the females, but the males reached a difference of 70 gm at the end of the test The food intake and conversion of these rats were also lower than those of the controls (Table 2) No other clinical changes were noted

Post-mortem examination after 9 *weeks* In the rats killed after 9 weeks feeding, macroscopic lesions were confined to the liver of those rats fed Brazilian groundnut meal. The surface of the liver was smooth, with numerous sub-capsular yellow focal

Stock diet (containing 10 per cent groundnut meal)	—	—	0/243	1/257

Rats 6–12 mths old

* One death at 6 weeks

lesions 1–2 mm diameter The kidney appeared normal, but sections showed some hydroptic change in the tubules No macroscopic or microscopic lesions were found in the liver and kidneys of the rats in either of the control groups

Post-mortem examination after 30 weeks In the rats killed at the end of 30 weeks feeding, macroscopic lesions were confined to the livers and lungs of the rats fed the Brazilian groundnut meal The other organs—heart, spleen, kidney, adrenal, intestinal and urogenital tract—all appeared normal The livers of all rats in this group were grossly abnormal, twice the weight of the controls (Table 3) with a brownish yellow irregular nodular surface, red and greenish cysts and numerous (1–2 mm diameter) yellowish focal lesions The nodules consist of liver tumours of three types solid yellowish lobulated hepatomas, and blood- or bile-filled cysts Of the 11 rats in the group fed Brazilian groundnut meal, 9 had macroscopic tumours, and two of these rats also had secondary deposits in the lungs The yellow focal lesions seen in all the livers in this group are similar to those found in the rats killed at 9 weeks

In the control animals, one hepatoma was found in the group fed the control groundnut meal, but no focal lesions were seen There were no macroscopic lesions in the rats fed the purified diet

The kidneys were all macroscopically normal, but in the group fed Brazilian groundnut meal, sections show some glomerular and tubular changes In some glomeruli there is a homogeneous eosinophilic deposit on the glomerular membrane Some tubules show a few greatly enlarged hydroptic cells, these have very large vesicular nuclei and much vacuolated cytoplasm No changes were found in the kidneys of control rats

The lungs all show various stages of the rat pneumonia complex, however, in two rats fed Brazilian groundnut meal macroscopic greyish lesions 2–3 mm in diameter with a wide surrounding zone of hæmorrhage were found Sections show infiltration with anaplastic hepatoma cells, with mitosis, and a wide outer zone of alveoli filled with alveolar phagocytes and red blood cells Control rats show only the lesions of the rat pneumonia complex

We have therefore found that the feeding of a known toxic sample of Brazilian groundnut meal to rats failed to reproduce the acute liver damage which occurred in turkey poults The growth of male and female rats was depressed, but this was accompanied by a reduced food intake and lowered food conversion ratio (Table 2) Diets containing the toxic meal were unpalatable and reduced the growth-rate in turkey poults[1]

After six months feeding of 20 per cent Brazilian groundnut meal in a purified diet, 9 out of 11 rats developed multiple liver tumours, and 2 of these had lung metastases This finding indicates that this diet is carcinogenic In comparison the breeding stock show a very low incidence of liver tumours (Table 3) The presence of liver tumours in the absence of cirrhosis, cell necrosis, or cellular infiltration suggests that the toxic agent acts directly on the hepatic cells

The nature of the toxic agent is at present unknown, so far all the attempts to show significant amounts of known toxic substances have been negative[1], and in spite of the resemblance of the liver lesions in turkey poults to those produced by *Senecio* alkaloids these have not been found in the toxic extract[4] The presence of the toxin in groundnut meals from other sources has been reported[5], but our finding of a single hepatoma in rats fed the control Indian groundnut meal is not conclusive evidence for the presence in this sample of the carcinogenic agent

Extracts of the meal are now being tested for their hepatotoxic and carcinogenic effect in rats, but we think that these unexpected preliminary results are of general interest

LARGE numbers of turkey poults[1] and ducklings[2] died on British farms in 1960 as a result of consuming groundnut (*Arachis hypogaea*) meal imported from Brazil Afterwards, outbreaks of disease associated with the feeding of Brazilian groundnut meal were reported in cattle[3], pigs[4], and sheep (Buxton, J C , personal communication) More recently it has been shown that some samples of groundnut products from a number of other producing countries are toxic to animals[5]

Toxic groundnuts cause hepatic changes in all the species mentioned In cattle, the disease has been reported as indistinguishable from ragwort (*Senecio jacobea*) poisoning[3] In rats fed on a diet containing toxic groundnut meal for 6 months, carcinoma of the liver developed (Lancaster, M C , *et al* , preceding communication)

Earlier work[6] provided a sensitive biological method of detecting toxicity in groundnut products and the active substance was concentrated 250 times We have now further purified the toxic extracts from Brazilian groundnut meal by chromatography on alumina and obtained a crystalline though still not pure substance which produces the same biological effects in ducklings Twenty μgm. of this material given orally is fatal to day-old ducklings in 24 hr , and considerably less produces the characteristic histological liver lesions

The toxic substance is almost colourless, and on paper chromatography on Whatman No 1 paper in *n*-butanol–5 per cent acetic acid gives a single spot, R_F 0 7, which emits a bright blue fluorescence in ultra-violet light The amount of fluorescent material estimated visually to be present in the spots produced in this way from numerous samples has invariably corresponded with the toxicity of the sample as determined biologically We are now using this method to select samples for biological testing, when a little more is known of the physical and chemical properties of the toxic material we have every hope that the method will provide the basis of a routine chemical test

It was suspected that the toxic substance might be a fungal metabolite since a highly toxic sample of nuts from Uganda which had been associated with the deaths of ducklings in Kenya was seen to be heavily contaminated with fungi

Pure cultures of certain of the fungal species present in this sample were produced and those of eight isolates, grown for 7 days at 27° C on Czapek's solution agar, were extracted with chloroform. The extract from one of these was shown to contain a fluorescent material, R_F 0 7, in *n*-butanol–5 per cent acetic acid These extracts were dosed to groups of day-old ducklings and those receiving the fluorescent extract died with the characteristic histological liver lesions of toxic groundnut poisoning The dose required was also of the order expected from a consideration of the amount of the fluorescent material present The toxin-producing fungus was next grown on heat-sterilized, non-toxic groundnuts After 7 days at room temperature extracts prepared from the visibly mouldy nuts were shown to contain the blue-fluorescent material and to be lethal to day-old ducklings, producing the typical liver lesions

The toxin-producing fungus has now been identified as *Aspergillus flavus* Link ex Fries

Further work on several aspects of this problem is now being pursued Thus the toxic substance is being prepared in a pure state from cultures of *A flavus* for comparison with the crystalline material isolated from the toxic groundnut meal, and then for detailed chemical and biological study Examination of other fungi isolated from groundnuts is also being continued to discover whether they produce a toxin Development of a routine chemical test for the toxin is also in hand, while other sections of the Tropical Products Institute are studying the incidence of fungal attack on groundnuts in the tropics and the steps necessary to prevent it Finally, we are examining possible economic methods of making toxic meals safe

Since strains of *Aspergillus flavus* are among the commonest fungal contaminants of cereal grains[7], it would not be surprising if some grain samples were found to be contaminated with the toxic metabolite described We intend to study this problem

We wish to thank Mr J J Elphick, of the Commonwealth Mycological Institute at Kew, for identifying the toxin-producing fungus

Leaf Vernalization

Vernalization is the indirect stimulating effect of low temperature on subsequent flower formation in high temperatures So far seed vernalization and plant-vernalization are known In winter annuals vernalization of germinating seed is effective In biennials seed vernalization has no visible effect, but 'adult' plants—which have passed the juvenile phase—can be vernalized

In their classical experiments, Gregory and Purvis[1,2] and Purvis[3,4] demonstrated that in *Secale cereale* variety Petkus the locus of seed vernalization lies within the embryo and more specifically in the stem apex Curtis and Chang[5] found that in celery the terminal meristems of the stem can be vernalized Further investigations on the locus of plant vernalization are unknown, but it is believed that the stem apices, or the buds, are the only organs that perceive vernalizing temperatures However, recent experiments have shown that leaves can be also vernalized

These experiments were carried out with leaf cuttings of honesty, *Lunaria biennis* According to former investigations[6] this plant is a typical cold-requiring biennial Hagemann[7] demonstrated that leaf cuttings, consisting of a complete leaf with part of its petiole but without a bud, regenerate easily and reproduce the developmental phase of the plant of origin leaf cuttings from vegetative plants remain vegetative, but those of generative plants will flower Unpublished results by me have shown that translocation of a 'flowering stimulus' from vernalized scions to unvernalized stocks may occur

The experimental approach to leaf vernalization was quite simple Leaf cuttings of juvenile and adult plants, 6 and 12 weeks old respectively, were obtained These cuttings were made of leaves of approximately the same age and were exposed to 5° C during 12 or 20 weeks and afterwards grown at ordinary greenhouse temperatures None of the cuttings from juvenile plants flowered Of the adult plants none of the 25 controls flowered, but 3 out of 17 (17 per cent) and 21 out of 24 (88 per cent) after 12 weeks and 20 weeks of vernalization, respectively, flowered quite normally They had visible flower buds after. respectively, averages of 219 and 182 days from the day of cutting The cuttings had started root formation while at 5° C , but no bud had yet regenerated Consequently, vernalization of leaf plus part of petiole without a bud had taken place

Two additional points are of interest First—and this is quite remarkable—the juvenile nature of the original plants is maintained in the leaf cuttings Secondly, leaves from adult plants require more cold than whole plants, as 9 weeks of 5° C and sometimes less are already sufficient for complete vernalization of 12-week-old plants[6]

Two possibilities offer themselves as explanations of leaf vernalization (1) The whole leaf is vernalized resulting in the production of a flowering stimulus which is translocated to the regenerating new plant The results of Hagemann and of my own grafting experiments tend to support this possibility (2) Each meristematic cell is subject to vernalization and reproduces the vernalized condition by mitosis to the newly regenerating plant It is difficult to choose between these possibilities, but experiments are under way to settle this question

The investigation has been extended by growing the leaf cuttings at ordinary greenhouse temperatures for 2 weeks before the cold treatments started This was done on the supposition that the cuttings would stand the cold treatments better After all, it has turned out to be unnecessary, but rather unexpected results were obtained. percentages of flowering between 72 and 87 per cent in the four groups of 6- or 12-week-old plants and 12 or 20 weeks vernalization It should be realized that the leaves from the 6-week-old plants were 2 weeks older when the cold treatment started, and according to former results plants of 8 weeks old are usually adult Furthermore, root formation had started when the cuttings were exposed to low temperature, while a number of them had formed buds during the cold treatment However, cuttings without buds at the end of the vernalization have flowered, while for the rest the experiments without a 2-week warm period and without buds formed in the cold are conclusive enough The favourable effect of a preceding root formation remains unexplained

Finally, some side-results with regard to the influence of low temperature on the regeneration are worth while mentioning. All cuttings formed roots quite readily All cuttings from 6-week-old plants without cold treatment regenerated sprouts after an average of 89 days Only 52 per cent of the cuttings from 12-week-old plants without cold treatment regenerated sprouts after an average of 169 days After cold treatment, however, 100 per cent regenerated sprouts after approximately the same time as the comparable 6-week groups Judging by the average numbers of sprouts per plant the low temperature had a decidedly favourable effect: 1 3–2 6 in the 6-week group and 1 2–4 8 in the 12-week group

In conclusion, leaf vernalization is possible when the leaves are taken from adult plants On the other hand, the regeneration of sprouts is much better when the leaves arise from juvenile plants Low temperature has a decidedly favourable effect on this regeneration

A Potent, Non-Toxic Plant-growth Inhibitor from an Antibiotic Fermentation

THE production by micro-organisms of substances inhibitory to the growth of higher plants is well documented. The purpose of this communication is to report a potent inhibitor of plant growth, as measured by our duckweed (*Lemna*) test[1] Solvent extraction at *p*H 9 0 of filtrates derived from fermentations of an unidentified *Streptomyces* led to the recovery of a light tan solid, designated crude *PA*-180 This preparation exhibited considerable antibiotic activity against various micro-organisms (for example, minimum inhibitory concentrations of 3 12 and 6 25 µgm /ml against *Streptococcus faecalis* and *Corynebacterium diphtheriae*, respectively, we wish to thank Dr A R English for the anti-microbial testing and Dr T M Lees and Mr M Lynch for papergram determinations). This crude *PA*-180 preparation also was shown to exhibit remarkable plant growth activity This inhibitory effect was first noticed in a routine test being conducted for an evaluation of its growth effect and its phytotoxicity The results (Fig 1) were noteworthy since they demonstrated a strong inhibitory action with no apparent toxic symptoms The plants at all test-levels were normal except for a decreased size The original experimental transfer consisted of one rosette of four fronds These four original fronds are easily detected among the tiny daughter fronds at the 5, 10 and 20 p p m test-levels The number of fronds is not appreciably decreased, as opposed to the size and weight of the plants

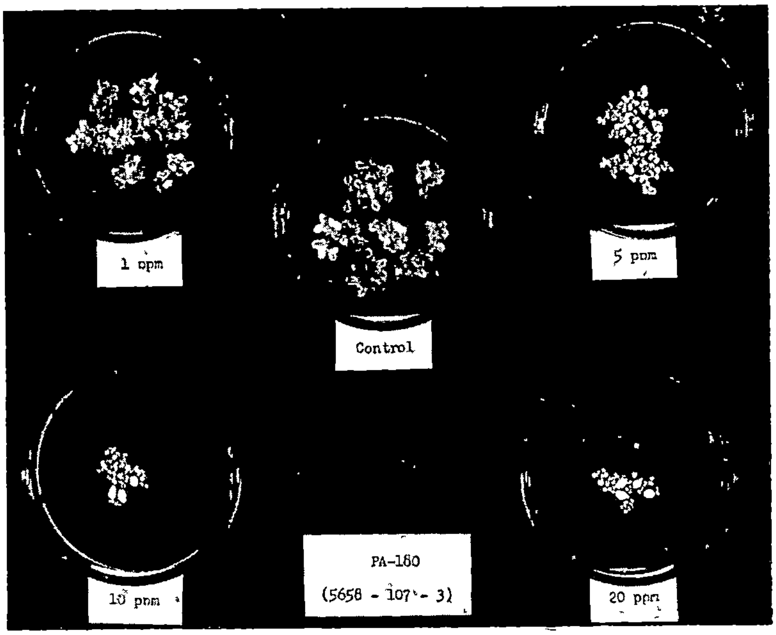

Fig 1 Effects of a preparation of *PA*-180 on the growth of *Lemna minor* under aseptic conditions on a liquid synthetic medium The dwarfing effect is apparent at 5 p p m and more The original four leaves of the rosette used for inoculation are clearly shown at these same levels

The effect of this new inhibitor on the fresh weight of *Lemna minor*, a small aquatic duckweed grown under aseptic conditions on a simple, synthetic liquid medium, is shown in Table 1 along with similar data in this test using several microbial metabolic products, including antibiotics and some well-known plant-growth and general metabolic inhibitors Present investigations are being conducted for the purpose of determining how widespread this inhibitory action is and the range of plants affected, including the lower forms Preliminary results show inhibition of (1) several plant tissues *in vitro*, (2) cucumber seed germination, and (3) growth of barley and several other seedlings

Efforts were then directed toward the preliminary characterization of crude *PA*-180 Papergram

Maleic hydrazide (ref 17)	0	−10	−25	−40	root inhibition at 10–20 p p m

investigations utilizing various chemical and physical detection techniques disclosed a heterogeneous nature for the material Bioautographs showed the presence of one dominant antibiotic substance Work with eluates of papergram sections (with several culture strains) led to detection of plant-growth inhibitory activity dissociated from that of the dominant antibiotic component, heat stability of the plant factor was also demonstrated It is apparent that the plant factor is a small but potent fraction of crude *PA*-180 Thousands of materials have been screened to date in this test, but none has demonstrated the amount, type and reproducibility of plant-inhibitory activity associated with crude *PA*-180, with the possible exception of another actinomycete fermentation preparation (at present being compared with the *PA*-180 product).

Antennary Feeding of the Hermit Crab *Diogenes brevirostris* Stimpson

THERE exist only two previous descriptions of feeding behaviour in hermit crabs, namely, those of Thompson, who described the feeding of *Eupagurus longicarpus* Say , and of Orton on *E bernhardus* (L) Orton[1] says that both species feed by scooping up debris directly with either the third maxillipeds or with the small chela The material is brushed between the third maxillipeds, and the rejected portion falls to the ground The antennæ and the walking legs play no part in the feeding of these animals

Diogenes brevirostris Stimpson usually feeds by scraping debris towards the third maxillipeds with the second and third walking legs, and the small chela The material is picked up by the endopods of the third maxillipeds, scrubbed between the brushes of the propus, dactylus and merus, and then passed on to the endopods of the second maxillipeds. These brush the debris further and pass the food to the mouth, the inedible portions being carried away in the exhalent respiratory current Small pieces of algæ may be picked from stones by the small chela and passed on to the mouth parts and so to the mouth

The alternative method of feeding can be described as antennary cast-net feeding. The flagellum of each antenna bears two rows of plumose setæ These are about 3 mm long and set widely apart, each being separated from its neighbour by 0 2 mm The setæ of the two rows curve in towards one another so as to form an obtuse and reflex angle between them The animals normally make occasional cleaning movements of the antennæ, bringing them down alternately to the endopods of the third maxillipeds, which clean them by wiping off the debris caught on the setæ The antennæ then resume their normal resting position, the oblique angle between the setæ facing downwards and slightly laterally If, however, food particles are caught on the setæ, the antennæ begin rapid to-and-fro movements These are interspersed with cleaning movements after every three or four sweeps, and the adhering particles are removed by the maxillipeds and eaten During each sweep the antennæ are twisted so that the oblique angle between the setæ faces in the direction of the sweep. If the animals are feeding in a water current the antennæ are not swept, but merely kept with the oblique angle between the setæ facing into the oncoming current so as to catch the suspended particles. The antennæ are then cleaned in the normal manner. Sorting of the edible and inedible fractions takes place in the usual manner.

Cast-net feeding occurs in other Crustacea but appendages other than the antennæ may be used. Thus *Porcellana longicornis* (L.)[2] and *Haplocarcinus marsupialis* Stimpson[1] use the third maxillipeds as cast-nets. The use of antennæ as cast-nets is found in the nauplius larvæ of *Artemia salina* (L.)[3], while two anomuran sand crabs, *Emerita talpoidea* (Say), and *E. analoga* Stimpson, are also known to feed with their antennæ. They feed in the wash of the waves on the shore, with their antennæ extended as nets. It is reported that *E. analoga* can feed in quiet water by waving its antennæ, but that *E. talpoidea* cannot feed in quiet water at all[4]. There is, however, a distinct difference between the structure of the antennæ of *Emerita* and *Diogenes*. The flagellum of each antenna of *E. austroafricana* Schmitt has two double rows of setæ, the outer setæ of each pair bearing long setules, and the inner short setules. These crabs depend almost exclusively on cast-net feeding, and correlated with this carry on their antennæ a dense feltwork of setules which can trap both large and minute particles. This is not true of *Diogenes brevirostris*, which uses its antennæ only as accessory feeding devices.

Spawning Mechanism in the Male Lugworm

IT has been shown[1] that the male lugworm (*Arenicola marina*, L.) can be induced to spawn by injecting into the body-cavity the lipid fraction of tissue extracts of whole worms. It was suggested that release of lipid into the body cavity might provide the immediate (internal) stimulus for spawning under natural conditions. The validity of this suggestion can only be tested when the mechanism by which the gametes are emitted is thoroughly understood.

In the lugworm the gametes develop in the body-cavity for a prolonged period and are eventually shed through the nephromixia[2]. The problem in the elucidation of the spawning mechanism lies in the fact that during their development the gametes must be rejected by the ciliated funnels of the nephromixia so that they are retained in the body-cavity, whereas when spawning commences they must suddenly be accepted by the ciliated funnels so that they are shed.

The answer to this problem suggested itself in the experiments, mentioned above, in which tissue extracts were injected into male worms. It was noted that before the worms began to spawn the spermatozoa in the cœlom, which are normally bound together in morulæ, became dissociated forming a dense suspension of free spermatozoa. It seemed possible that whereas sperm morulæ were rejected by the nephromixia, free spermatozoa were accepted by them so that shedding automatically ensued. This possibility has since been tested in a series of experiments in which samples of free spermatozoa were injected into the body-cavities of male worms which were not themselves spawning. Samples of free spermatozoa were obtained by concentrating sperm suspensions spawned naturally by centrifugation, or by treating cœlomic sperm *in vivo* or *in vitro* with lipid extract. The lipid was afterwards separated, again by centrifugation. As it could be argued that free spermatozoa obtained by both these methods might be contaminated with a natural spawning stimulant, samples of free sperm were also obtained by treating cœlomic sperm with alkali. The *p*H of the suspension was afterwards adjusted to 7·5. Untreated cœlomic sperm was administered to control worms. 1·0–1·5 ml. of one of these concentrated suspensions was administered to each test worm, the total number of free sperm injected having been estimated previously by counts using a 'Metz' hæmocytometer. With the exception of the controls, shedding ensued in every case, usually less than 1 hr. after injection of the free spermatozoa (Table 1). It would appear, therefore, that free spermatozoa are accepted automatically by the nephromixia and shed. It is possible, however, that shedding under natural conditions is not entirely passive. In these experiments spermatozoa were shed from the pores of the nephromixia much less vigorously than in normal spawning. Furthermore, estimates of the number of free sperm remaining in the body cavities of the test worms after shedding had ceased showed that in most cases only a third to a half of the total free sperm injected had been shed (Table 1).

Table 1. COUNTS BY HÆMOCYTOMETER OF FREE SPERM INJECTED INTO MALE WORMS AND OF THE NUMBER REMAINING IN THE BODY CAVITY AFTER CESSATION OF SHEDDING

Worm No.	Type or treatment of injected sperm	Total free sperm ($\times 10^9$) injected	Spawning occurred in (+)	Time of spawning (min.) after injection	Total free sperm ($\times 10^9$) in body cavity after spawning ceased
1	Naturally spawned	2·0	+	24	0·3
2	Naturally spawned	3·1	+	10	not counted infected
3	Naturally spawned	3·1	+	28	not counted infected
4	Extract (*in vitro*)	8–10·3	+	90	3·2
5	Extract (*in vitro*)	8–10·3	+	overnight	8·4
6	Extract (*in vitro*)	8–10·3	+	60	5·3
7	Extract (*in vivo*)	8–12·6	+	28	2·9
8	Extract (*in vivo*)	8–12·6	+	14	3·0
9	Extract (*in vivo*)	8–12·6	+	13	2·5
10	Alkali (*in vitro*)	11·0	+	9	4·1
11	Alkali (*in vitro*)	11·0	+	overnight	10·9
12	Alkali (*in vitro*)	11·0	+	15	4·1
13	Control untreated	1·75	—	—	—
14	Control untreated	1·75	—	—	—
15	Control untreated	2·0	—	—	—
16	Control untreated	2·0	—	—	—

While no great accuracy can be claimed for these counts due to difficulties in estimating the volume of the cœlomic fluid in each worm, it is clear that substantial numbers of free spermatozoa were usually retained in the body cavity. Even in the controls substantial numbers of free sperm were present in the suspension injected (due to handling of the suspension and to the fact that it was exposed to the air for some time) and none of this sperm was shed. This suggests that in normal spawning there is more active uptake of free sperm from the body-cavity. On the other hand, it was noticeable that when concentrated suspensions of naturally spawned sperm were injected there was more complete evacuation of free sperm from the body cavity although it was only possible to make one count (Table 1) Furthermore, when a microscopic examination was made of the suspensions of free spermatozoa produced by treatment with extract and alkali, it did appear that although the sperm morulæ had been broken down there was a tendency for the spermatozoa to continue to adhere together by their tails It may have been for this reason that many apparently free spermatozoa were not shed whereas the naturally spawned sperm was completely dissociated and thus accepted more readily by the nephromixia The correct interpretation of this evidence was suggested in similar experiments with female worms, which are reported at greater length elsewhere[3] In these it was shown that maturation of the ova immediately precedes the onset of shedding This suggested that mature eggs might be accepted by the nephromixia whereas immature eggs are rejected. Mature eggs which had been spawned naturally were collected and concentrated As in the experiments with males, these were injected into test worms which were not spawning Shedding immediately ensued, but again only about half of the material injected was emitted. It appears, therefore, that emission of the gametes in *A marina* involves primarily a change in the nature of the gametes which is associated with their maturation so that they can be accepted by the ciliated funnels of the nephromixia, and secondly, there may also be some form of active uptake of the gametes by the nephromixia

VIROLOGY

Cytopathic Protective Factor : its Production by Normal Uninfected Serum-free Cell Cultures

At the present time two well-defined systems of viral interference by cell products have been demonstrated *in vitro* They are interferon[1] and viral inhibitory factor[2], the latter possibly being a variety of interferon Both at least have in common the fact that they are produced in cell cultures infected with virus, active virus in the case of the latter, or inactivated where interferon is concerned Other differences and similarities are discussed in a recent report by Ho and Enders[3] It is well known that virus inhibitors are present in a variety of mammalian tissues and fluids[4] and may be demonstrated either *in vivo* or *in vitro*

In the process of searching for biologically synthesized inhibitors for viruses, it was discovered that a line of serum-free mouse lung cells produced a substance which 'protected' heterologous cells from destruction by influenza virus The lung cells were originally isolated from lung tissue of new-born white Swiss mice on a medium of 10 per cent horse serum and 90 per cent medium 199 They were afterwards adapted to rapid growth on a medium consisting of 1 per cent peptone, 100 mgm per cent dextrose, and 99 per cent medium 199 (ref 5) They have been designated the *MPD*1 line of cells It had also previously been shown that the serum-free cells were equally as susceptible to vaccinia virus infection as the original serum-containing parent strain[6] Neither line of cells showed any response to dilute or undilute influenza viruses *PR*8, Asian, Lee *B*, or *B*54, when 40-hr or older cultures were used.

Two additional cell lines, one designated *UIRHM*1 (University of Illinois rabbit heart mark 1) isolated from normal rabbit heart tissue, and one designated *UIKM*1 (University of Illinois keratoacanthoma mark 1) isolated from a human keratoacanthoma lesion[7], are fully susceptible to all four of the influenza viruses previously mentioned Both these cell lines contained 10 per cent calf serum as a supplement to the base medium 199 The cytopathic effect of the virus was evidenced as a pronounced cytoplasmic vacuolation with eventual cell destruction in the *UIKM*1 cells In the case of the *UIRHM*1 cells the destruction of cells occurred without cytoplasmic vacuolation These cytopathic effects could be prevented by specific antiserum, and occurred within 48 hr of virus inoculation

Following the basic recognition that such a phenomenon occurred with *MPD*1 fluids and influenza virus, it was decided to develop and control an investigation into this 'protective' effect.

Cultures of *UIRHM*1 and *UIKM*1 cells were seeded in a volume of 5 × 10^5 cells per ml in 1-ml Leighton tubes and incubated at 37° C for 24 hr At the end of this time, the supernatant fluid was removed and the cells were covered with 1 ml of pooled 6-day supernatant fluids from *MPD*1 cells 5 min after the addition of the 6-day old fluid, the cultures were inoculated with 0 05 or 0 1 ml of a specific strain of influenza virus, either *PR*8 or *B*54, which had been grown in chick embryos Controls consisted of normal cultures, cells which were reared with maintenance media (99 per cent Hanks balanced salt solution and 1 per cent calf serum), and cells to which complete fresh peptone 199 media was added In addition to these, a third series of tubes received an overlay of pooled *MPD*1 supernatant fluid to which had been added concentrated medium 199 and calf serum so that the amount of these substances present was equal to their original concentration in the test cell media The cells were re-incubated at 37° C and viewed microscopically at 17, 24, and 40 hr The cytopathic response was graded as 0, 1+, 2+, 3+, or 4+ Under this system, 0 would indicate no cytopathic response or complete cell protection, 1+ as 25 per cent, 2+ as 50 per cent, 3+ as 75 per cent, and 4+ as 100 per cent cytopathic effect

Results showed complete protection against cytopathic effect of both influenza viruses in the two cell lines In addition, it was found that this same protection occurred when Lee *B* or Asian influenza viruses were used This protective fluid was afterwards named cytopathic protective factor

In order to standardize future work, a test system composed of *UIRHM*1 cells and *B*54 virus was chosen The standard inoculum was approximately 3 × 10^5 tissue cells per ml of fluid and 0 1 ml of *B*54 chorioallantoic fluid virus, containing $10^{7\cdot 1}$ 50 per cent chick embryo infective doses (EID_{50})

In order to determine the concentration of cytopathic factor in the supernatant fluids, the following experiments were set up Fluids from pooled 6-day harvests of *MPD*1 cells were diluted from 1 2 up to 1 512 in two-fold steps in complete growth media The fluid from 24–72 hr old *UIRHM*1 cells was decanted and the cells overlayed with specific cytopathic factor dilutions, and the standard testing procedure carried out Four tubes were used for each dilution, as well as the normal control series It was possible to dilute the cytopathic factor 1 16 and still protect 75 per cent of the cells A dilution of 1 8 afforded 100 per cent cell protection

At this point it was considered vital to know whether the cytopathic factor acted on the cell *per se* or the virus particle To resolve this problem, the fluid from 24-hr old cultures of *UIRHM*1 cells was decanted and the cell sheet was overlayed with undiluted cytopathic factor fluid and incubated for 1, 3, 6, and 20 hr at 37° C At the end of this time, the fluids were removed and replaced by complete growth media and 0 1 ml of *B*54 virus No protection occurred at any of the periods tested, showing that the cytopathic factor was not adsorbed to the cell sheet.

To test the action of cytopathic factor on influenza virus, *B*54 virus was diluted 1 10 in the undiluted factor fluid and incubated at 37° C for 1, 3, 6, and 20 hr At the end of this time, the virus was sedimented by centrifugation at 81,000*g* for 30 min The fluid was decanted and the virus re-suspended, to its original stock concentration, in complete growth media and used in the standard test system The virus was fully as toxic to *UIRHM*1 cells as untreated virus, indicating that the action of cytopathic factor is not directed against the virus *per se* The lack of action on the virus was further demonstrated by its negative reaction in hæmagglutination inhibition tests.

In order to determine the period of formation of cytopathic factor, the following experiment was designed Six 10-ml flasks of *MPD*1 cells were inoculated with 4 × 10^5 cells per ml and incubated at 37° C. At the end of 24 hr , and every 24 hr for a total of 6 days, the entire 10 ml of supernatant fluid was harvested and stored frozen When all fluids had been collected, they were tested for the presence of cytopathic factor by the dilution method mentioned The fluid was negative for protective capacity at 24 hr , became positive at 48 hr , and increased to a maximum at 5 days The period between 24 and 72 hr is undergoing further investigation

Present results indicate that the cytopathic factor differs mainly from interferon and viral inhibitory factor in that it is produced in uninfected cultures and not as a result of contact with viruses, either active or inactive It is similar to viral inhibitory factor in that it neither acts on the virus *per se* nor is adsorbed to the cell sheet Interferon, on the other hand, is readily bound by test cells The cytopathic factor appears to be a natural cell product protecting against the cytopathic effect of influenza virus in the cells from which it originates as well as cells from human and rabbit sources Further, it has not been found in the parent cultures containing serum of the *MPD*1 line Since both virus infection and adaptation to serum-free media must represent a traumatic experience to the cell, there is the possibility that other manipulations of this type will produce similar materials That the protection crosses species barriers at a cellular level is not startling, since it has been shown by Alfred and Pumper[8] that the supernatant fluid from *MPD*1 cells or purified portions of it can act as a serum replacement for human liver cells *in vitro*

Cytopathic factor had been used in attempts to protect the *UIKM*1 line of cells against coxsackie, mumps, vaccinia, poliomyelitis, and adenoviruses to which this cell line is susceptible, without success Thus it appears to be specific for influenza viruses Experiments to determine its physical and chemical properties and site of action, as well as work on its purification, are in progress

MISCELLANY

The Grayling Fish and River-Names

The grayling fish belongs to the family Thymalidae and is closely related to the family Salmonidae It offers, I believe, a new and tenable explanation for the much-disputed origin of the river-names 'Thames' and 'Humber'

When, in British prehistory, these Rivers were so named, fishing was a vital industry, certainly more so than agriculture, and possibly more than hunting. Our rivers were, in those remote days, teeming with fish, and especially fish of the salmon family, so that nothing could be more natural than that some of these rivers should be named 'grayling-river'

'Grayling' is a name of germanic origin (cf German *grau*) But in medieval English the grayling fish retained two names of non-germanic origin *thyme* and *umbre* The 'thyme' word for a grayling is due to the fact that the fish has a smell closely resembling that of the herb of the same name The word is related to Latin *thymallus* (a fish smelling of thyme) and to Greek θύμος, the herb 'thyme' (θύω, 'to smell') The 'umbre' word for a grayling is due to its grey and shadowy appearance, and may be cognate with, if not directly descended from, Latin *umbra*, 'shade' (*umbra* was a Roman word for a grayling fish)

In his book, *Der Flussname Thamse unde seine Sippe* (1941), Prof Max Forster reaches the conclusion that the meaning of 'Thames' is 'dark river' For 'Humber', Prof Eilert Ekwall (*Oxford Dictionary of English Place Names*) suggests that the meaning is 'good-river'.

However, I submit that there is a *prima facie* case for expert investigation of the hypothesis that both the Thames and the Humber, and the groups of river-names associated with them, are so called because of the grayling fish that frequented them—the Thames on account of the smell, and the Humber on account of the colour

If this is acceptable, it has some bearing on the origins of the language spoken by the natives of Britain before the Romans arrived

John Tutin

FORTHCOMING EVENTS

Monday, December 18

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr F J D Taylor "Large Microwave Steerable Aerials for Communication with Artificial Earth Satellites and Space Probes".

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Meeting on "The Mothproofing of Wool"

Institution of Mechanical Engineers, Education and Training Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "The Teaching of Machine Tool Technology as an Academic Subject"

Tuesday, December 19

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr K G King "The Use of Controllable Semiconductor Rectifiers in Machine Control".

Wednesday, December 20

Royal Meteorological Society (at 49 Cromwell Road, London, S W 7), at 5 p m —Scientific Papers

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W 1), at 5 p m —Meeting on "The Provision and Use of Pathogen-free Laboratory Animals" Speakers Dr W Lane-Petter, Dr D G Davey and Dr. A O Betts

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Dr R L F Boyd "Satellite Instrumentation"

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S W 1), at 6 p m —Discussion of recently published papers

Thursday, December 21

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p m —Prof B V Derjaguin (U S S R) and Mrs N D Shukakidse (U S S R) "Dependence of the Floatability of Antimonite on the Value of Zeta-Potential", Dr J D Peacock and Mr R Williamson "Radon Determination as a Prospecting Technique"

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Prof G W Mackey "Some Connections between Ergodic Theory and Group Theory"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer in Mathematics—The Principal, College of Education, St Andrew Street, Aberdeen (December 26)

Organic Chemist or Biochemist (with a good honours degree or equivalent qualification), for research in structural carbohydrate chemistry and immunochemistry—The Secretary, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S W 1 (December 30)

Chair of Applied Physics—The Registrar, The University, Hull (December 31)

Chair of Sociology—The Registrar, The University, Hull (December 31)

Lecturer in Geography, a Lecturer in Physics, and a Lecturer in Psychology at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

Lecturer or Senior Lecturer in Genetics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

Lecturer (with an honours degree in biochemistry or chemistry with subsequent research and/or teaching experience in some branch of biochemistry) in Biochemistry at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

Lecturer (with some experience in computing, preferably in connexion with electronic machines) in Computing—The Registrar University College of Wales, Aberystwyth (December 31)

Reader or Senior Lecturer in Mathematics at the University College of Townsville, University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 31)

Assistant in Bacteriology (Science)—The Secretary of University Court, The University, Glasgow (January 3)

Lecturer in the Electronic Computation Laboratory of the Applied Mathematics Department—The Registrar, The University, Sheffield (January 6)

Lecturer or Senior Lecturer in Statistics in the Department of Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (Januarv 6)

Lecturer or Assistant (preferably with a special interest in solid state physics) in Physics—The Secretary, Queen's College (University of St Andrews), Dundee (January 8)

Lecturer (preferably candidate who can teach in the fields of Romano-British and/or Medieval English archæology) in Archæology—The Registrar, The University, Nottingham (January 13)

Chair of Anatomy in the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 15)

Lecturers in Physics—The Registrar and Secretary, King's College (University of Durham), Newcastle-upon-Tyne 1 (January 15)

Research Fellow (preferably with experience in elementary particle physics) in the Department of Theoretical Physics, Institute of Advanced Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W.1 (January 15)

Senior Demonstrator (with a science degree with a major in geology, and special qualifications and research experience in geomorphology) in Geomorphology in the Department of Geology —The Registrar, University of Melbourne, Parkville, N 2, Victoria, Australia (January 15)

Senior Lecturer (with special qualifications in analysis) in Mathematics, and a Lecturer and an Assistant Lecturer (with research experience in mathematics) in Mathematics in the Department of Pure Mathematics—The Registrar, University College of North Wales, Bangor, North Wales (January 18)

Professor (with a higher degree, preferably a doctorate, and research in the field of philosophy) of Philosophy at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 20)

Lecturer in Mathematical Statistics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 22)

Reader in Physics at St Bartholomew's Hospital Medical College —The Academic Registrar, University of London, Senate House, London, W C 1 (January 22)

Chair of the History of Science and Technology at Imperial College—The Academic Registrar,. University of London, Senate House, London, W C 1 (January 25)

Turner and Newall Research Fellow (with two or three years postgraduate experience, or industrial experience, and preferably some knowledge of semiconductor devices) in Applied Science, for research concerned with novel types of electrical machines of special significance to control engineering—The Registrar, University College of North Wales, Bangor, North Wales (January 25)

Lecturers (2) in Pure Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 26)

Chair of Engineering in the University of Malaya, Kuala Lumpur —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Kuala Lumpur and London, January 31)

Demonstrators (graduates with some research experience) in the Department of Organic Chemistry—The Registrar, The University, Liverpool, quoting Ref CV/575/T (January 31)

Lecturer in Physics—The Registrar, The University, Hull (January 31)

Official Fellow and Tutor in Physics, or a Lecturer in Physics—The Principal, St Hugh's College, Oxford (February 1)

Reader in Mathematics at the University of Western Australia —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, February 17)

Imperial Chemical Industries Research Fellows in Chemistry, Physics, Metallurgy, Engineering, Geology, Agricultural Science or related subjects—The Registrar, University of Wales, Cathays Park, Cardiff (March 5)

Lecturer (with a good honours degree in physics with chemistry as a subsidiary subject, and a Diploma in Education or Teachers' Certificate, or a good general degree with physics and chemistry, and at least five years teaching experience) in Physics with Chemistry in Nigeria—The Recruitment Attaché, Nigeria High Commission, 9 Northumberland Avenue, London, W C 2, quoting Ref G 13/3

Psychologist with a Research Unit engaged on laboratory and field studies of complexity of industrial tasks—H Murrell, Department of Psychology, The University, 22 Berkeley Square, Bristol 8

Research Fellow (Senior or Junior) (with a Ph D , and preferably postdoctoral research experience), for work on biochemical activities of intact intestine and of isolated subcellular fractions of intestinal mucosal cells—Dr J W Porteous, Department of Biological Chemistry, Marischal College, The University, Aberdeen

TECHNICAL AND SCIENTIFIC MAN-POWER IN BRITAIN

THE debate on technical and scientific man-power and research which was opened in the House of Lords on November 15 by Viscount Caldecote and Lord Shackleton drew a major speech from Lord Hailsham, the Minister for Science, in reply, but was also noteworthy for several constructive suggestions Viscount Caldecote's purpose was to direct attention to the significance of making full use of the technical man-power of Britain and to the need to devote more resources in research and development in industry to enable exports from Britain to compete effectively in the changing conditions of world trade, and he was confident that if we made full use of the scientific factor we could lead in many more fields He quoted with approval the view of Mr S P Chambers that we could keep our balance of payments straight only by being among the world's leaders in developing new products and new processes We had to export ideas and techniques as well as products

Viscount Caldecote emphasized the importance of making full and proper use of trained man-power in order to maintain the quality of products, but he was highly critical of the magnitude of expenditure on home advertising compared with that on research and development He was doubtful whether there is adequate co-operation between the universities and industry, and thought that there may be some duplication of research and development in the nationalized industries, particularly the service industries of transport, electricity and gas, where the emphasis should be on operational research He suggested that further investigation is required into the possibilities of collaboration between industry and the universities and colleges of technology, but his suggestion for the appointment of a scientific committee akin to the Public Accounts Committee to investigate whether the nation's scientific resources are being adequately, properly and economically used seems to disregard the Advisory Council on Scientific Policy, in spite of a compliment he paid to the Council's work

Viscount Caldecote also thought that the Research Associations should be expanded, though he agreed that some of the smaller associations might perhaps, with advantage, be amalgamated He advocated larger grants, including capital grants, and an inquiry into the reasons why industrial support is so limited He also pointed out the opportunities which the use of computers in management techniques may offer in gaining the full advantage of professionally trained staff, and he pressed the need to ensure that scientific and technically trained staff should have every opportunity to reach the highest positions

By and large, Viscount Caldecote was concerned to avoid the waste of trained man-power Lord Shackleton was concerned primarily to direct attention to the recent report of the Committee on Scientific Manpower on the long-term demand for man-power, of which he was both apprehensive and somewhat critical While he recognized the reservations which the Committee expressed in the report, he seemed to think that the mere suggestion of a possible surplus of scientists and technologists was unfortunate and that the Committee had not pointed out in anything like sufficiently forthright terms the value of employing scientists and technologists outside positions that are strictly professional Lord Marks referred particularly to the problem of the dissemination of information, which he regards as the greatest single difficulty, particularly among the small and medium-sized firms Lord Fleck, however, thought that little is likely to be gained by further inquiry into the use of technical man-power, but that it is much more important to improve the training of technicians and apprentices, particularly to make better use of the higher grade of recruits who now enter on such training. He agreed, however, that we could make far better use also of the most highly trained technologists and scientists at the top, but for this he looked not to the new computer techniques and the like but to the use of the human sciences and especially psychology

Lord Walston dealt more particularly with the character of the training which scientists and technologists should receive, and, while fully conscious that the Robbins Committee is examining the whole field, suggested that both the extent of university courses and the organization of the universities may require adjustment to meet the needs of to-day. Specifically, he suggested a rearrangement of academic terms which would in effect facilitate something like 'sandwich courses' (though he did not himself use the term) and in any event promote co-operation with industry for those studying social science as well as for students of engineering and science He also advocated closer co-operation between the colleges of technology and the universities, and was anxious that the colleges should have the status that conferment of a degree rather than a diploma would give

Lord Halsbury, who strongly supported the transfer of scientists and technologists across the economic structure, referred to their importance as administrators and on occasion as salesmen, he was highly critical of the efficiency with which they are used, particularly in the Government service, and of the way in which administrative delays hinder technical progress Lord Taylor was doubtful whether we are attracting sufficient of the ablest young minds into scientific and technical careers, attributing this largely to inadequate financial rewards as compared with those open to men who take up an administrative career He stressed, however, the need for some degree of planning if the resources of Britain were not to be too diffused, but thought that free consultation and co-operation, particularly by using the statistics which planning produced, might be an effective answer

Lord Hailsham, who replied, has within the past two months delivered three major addresses discussing the problems of science and Government in a free society, research in the universities, and again, in his Fawley lecture, to which Lord Taylor referred, science and Government All these issues in some aspects or other were raised in the debate, and Lord Hailsham's reply naturally reflected a good deal of his conception of his office as indicated in those addresses Nevertheless, his address in the House of Lords on November 15 was no mere repetition, and some of his comments were timely in a debate which once or twice seemed to reflect sensibility more than sense. Lord Hailsham commented that the demands on skill and knowledge for scientific and technical man-power in Britain are not exclusive demands, and are not substitutes for the knowledge of the arts and humanities or of the human sciences. He did not think that in any large respect an advance in science can any longer be obtained by getting out of the schools a much higher proportion of scientists as against humanists.

Lord Hailsham firmly defended the report of the Committee on Scientific Manpower, pointing out that the latest report was one of a series which went back as far as 1946 and that another survey would be made in January 1962. He maintained, moreover, that the prospects for any able young man or woman entering on a scientific or technological career are, and will remain, wider and better than ever before, and it would be a disaster if misinterpretation of the report made any such young people hesitate He stated that the Government is seeking accurate information about the numbers of technicians in training, and agreed that it is essential that highly trained scientists and technologists should be adequately supported in this way. The University Grants Committee is also considering this aspect of the effectiveness of university research

On the wider use of scientists and technologists outside strictly vocational fields, Lord Hailsham was in full agreement with other speakers He referred to the critical shortage of teachers of mathematics, and in a passing reference to university research, in which he put the current research grants from the Department of Scientific and Industrial Research at a total of £2,970,000, expressed the view that the greatest need is to encourage research in industry Industry, however, must in the end meet its own needs, and, turning to the Research Associations, although he agreed that the system could appropriately be re-examined and that there are several ways in which we could stimulate co-operative research, he was convinced that an approach which relied principally or primarily on State support is ineffective In this connexion, supporting what Viscount Caldecote and Lord Marks had said about libraries and the dissemination of information, he suggested that even firms which are too small to conduct research themselves could well afford the modest subscription to their Research Associations which would make available to them so much information on other people's experience in research

The difficulty here is, of course, that many such firms are not even aware of what they are missing, and that frequently they lack people capable of appreciating the significance for their own activities of current advances in science and technology. Here there might be a place for the scientific adviser, such as Lord Marks suggested, but though Lord Hailsham thought that the Department of Scientific and Industrial Research should encourage industrial research chiefly through the Research Associations and the work of its own research stations, he thought that there are two other promising possibilities One is in the work of the Department's Economics Committee, established four years ago, in promoting investigations providing information essential in determining future policy. The Committee's preliminary work has led to more detailed and technical investigations of particular industries, two of which, on machine tools and shipbuilding, have been completed, while others are in progress

Lord Hailsham believes that the machine tool project was outstandingly successful It had effected a decisive change of atmosphere and stimulated a much greater interest by the industry in education The design scholarship course sponsored by the industry at the Manchester College of Science and Technology is proving a great success, and schools of research are being developed in four institutions, to which the Department has already awarded research grants amounting to £170,000, and the industry has now established its own research association In addition, the National Engineering Laboratory is making an impressive contribution in this field, and several projects for civil development contracts are under investigation

The civil development contract is the other line of development which Lord Hailsham regards as particularly promising, and, quite independently of the work of the Economics Committee, the Department of Scientific and Industrial Research has been concerned with the general problem of large-scale development work and has been considering the use of civil development contracts to complement the work of the National Research Development Corporation Lord Hailsham said that the Department has now been authorized to proceed with two major projects, and, if these projects succeed, we may have achieved a major break-through in the relations between Government and industry in the encouragement of science Early in his speech, Lord Hailsham had referred to the long period of time required to bring any plan to fruition—and especially in regard to education. The production of leaders in science may represent the better part of thirty years effort, and it may be for no more than a further ten that they are at the height of their powers, and perhaps fifty years before the application of their discoveries really begins Nevertheless, he reiterated, in concluding, the importance of this connexion between education and man-power and productivity, and the ultimate dependence of progress on the devotion and creative inspiration of men of dedicated genius

Although the main interest of this speech of Lord Hailsham lies in his reference to the work of the Department of Scientific and Industrial Research, and in the indication it gives of his attitude to the Research Associations, it reflects very clearly his consistent adherence to the principles which he laid down in his earlier address on science and Government. He adheres firmly to the idea of the maximum freedom for the scientist and technologist, whether in industry or in the university The main task of the Government and its own institutions is to supplement and to stimulate, to correct the balance where necessary and to identify neglected areas in which some national effort is desirable It was not appropriate on that occasion for Lord Hailsham to enlarge on the detailed implications of that policy or philosophy, though some of the questions asked might have tempted him to do so He admitted, indeed, that the British system of training craftsmen and technicians needs a thorough overhaul, but otherwise made no reference to this aspect of the effective use of trained man-power On the dissemination of information and the place of libraries and information services he made no comment, although it should be a prime concern of the Minister for Science, or any such philosophy as Lord Hailsham expounds, to see that both the National Lending Library for Science and Technology and the National Reference Library for Science and Invention are adequately conceived and planned as part of a national system, and that the resources placed at their disposal are adequate to the needs, not just of to-day, but of the decades immediately ahead A firm adherence to the principles that fundamental research is best pursued at, or in close association with, the universities and that industrial research in the main is the business of industry, implies as a corollary that the Government has the responsibility to see that such ancillary services as library services, the supply and training of technicians and craftsmen, the provision of equipment, etc , for co-operative effort are generously adequate, and commensurate with national needs and technical potentialities rather than the limited horizons which may characterize a backward industry It is in such respects that the Minister for Science has yet to convince some of those who are most ready to applaud his policy and his philosophy that his actions are worthy of his ideas and his vision

CAPTAIN COOK'S VOYAGES

The Journals of Captain James Cook on his Voyages of Discovery

Edited by J C Beaglehole Vol 2· The Voyage of the *Resolution* and *Adventure*, 1772–1775. Pp clxx+1,021 (82 figures). (Cambridge At the University Press, 1961 Published for the Hakluyt Society) 120*s* net

ONE of the greatest explorers and discoverers of the eighteenth century, Captain James Cook, was responsible for important contributions to scientific knowledge After Cook had completed his first voyage round the world in the *Endeavour* (1768–71), during which the transit of Venus was observed at Tahiti, with the support of the Admiralty he was soon able to pursue his further strategic plan of discovery in the southern hemisphere By his own first voyage and by the work of others it had been proved that no southern continent of any magnitude could exist north of 40° south The next step, therefore, was to see whether such a continent could lie south of the fortieth parallel This Cook proposed to do by circumnavigation of the globe in high southern latitudes, taking advantage of the prevailing westerly winds His aim was amply realized. Leaving London with two ships in July, 1772, he arrived back in July, 1775, after an absence of three years and eighteen days Half-way through the voyage he had been parted from the *Adventure*, under Captain Furneaux, which returned to England alone But he carried on with his plan in the *Resolution* and returned in good order, having lost but four of his crew, only one of these by sickness As part of this remarkable feat of ingenuity and endurance, using New Zealand as a primary base with Tahiti as a secondary one, he made three major incursions into the antarctic and two into the tropical waters of the Pacific, each cruise yielding significant discoveries

Crossing the antarctic circle for the first time in history, he succeeded on one occasion in getting farther to the south (71° 10′) than any other nautical explorer on record up to the present day has been able to achieve He encountered a great deal of ice of various types which led him to many interesting observations Though he did not establish the existence of the antarctic continent, and indeed considered it probable that no land would be found to the south of the ice, he did incline to the view that the ice extended in a solid body to the Pole

Apart from the observations on ice and weather in these high southern latitudes right around Antarctica, Cook and his companions were responsible for various other important scientific achievements The hypothesis of a great southern continent in the temperate zones, so persistently advocated by Alexander Dalrymple and others, was finally disposed of In the tropical waters Cook, in pursuance of his plan, was able to confirm, systematize and extend in many particulars the discoveries of Pacific islands hitherto made His observations on the Tonga group and on the New Hebrides were particularly full and significant, and his own geographical discoveries included Palmerston Island and Niue.

From the scientific point of view, one of the most important contributions of this voyage was undoubtedly the success of the chronometer for the establishment of longitude Cook carried with him several of these instruments, not all of which were reliable, but the one which triumphantly proved itself was that made by Larcum Kendall as a duplicate of the fourth instrument made by John Harrison. Known as "Mr Kendall's Watch", this instrument received high praise from Cook and greatly facilitated the research of the astronomers aboard. The botanical and zoological records made by John Reinhold Forster and his son George, together with the anthropological and other observations of Cook and his companions, have now passed into the annals of the early scientific history of the Pacific.

This volume, like its predecessor (see *Nature*, 179, 390, 1957), is a model of editing. In the introduction to his first volume Dr Beaglehole rather prematurely stated that the study of Cook's journals is more complicated for the first voyage than for the second. In the introduction to this volume he remarks rather ruefully that the more the textual problem for this volume is scrutinized, the more complicated it becomes, since there is no existing original version—properly speaking—of Cook's journal on the *Resolution*. The editor deserves, therefore, all the more congratulations for the meticulous way in which he has accomplished his task. The text primarily used for this volume is that of a holograph manuscript in the British Museum, written by Cook. This has been supplemented by material from another parallel manuscript, also by Cook, which he used as a draft for printing his own *Voyage towards the South Pole*, which appeared in 1777. Readers who have known the latter will recognize the great value of the present edition for the expansion of the text, and for the scholarly introduction and abundance of footnotes which assist a great deal in the interpretation. In addition, extracts from officers' records, including that of Furneaux; the journal of William Wales, the astronomer, papers from the Board of Longitude respecting instruments and their use, some letters by Cook; and an admirably annotated calendar of documents add much to the story of the voyage. Of particular human interest in the penumbra of scientific activity is the account of the abortive attempt by [Sir] Joseph Banks (afterwards president of the Royal Society) to assume a leading part in the voyage. In his introduction, Dr Beaglehole seems to be rather hard on Banks. But his reproduction of Banks's own letter to the Earl of Sandwich, as First Lord of the Admiralty, makes it quite clear that Banks's concern for the size and accommodation of his own retinue weighed with him at that time more than a proper thought for the scientific objectives of the voyage. The volume is completed by an important series of maps and plans and many very effective illustrations, including a large number by Hodges, the official artist.

FLORA OF NEW ZEALAND

Flora of New Zealand

By H. H. Allan. Vol. 1: Indigenous Tracheophyta—Psilopsida, Lycopsida, Filicopsida, Gymnospermae, Dicotyledones. Pp. liv+1085. (Wellington: Government Printer, 1961.) 105s.

The publication of a new Flora of New Zealand is an event of supreme importance, and the work now available is a remarkable tribute to the industry and critical botanical sense of the author. Unfortunately, Dr Allan did not live to complete his formidable task of compilation and elucidation, and this book, which includes all indigenous vascular plants except the monocotyledons, was most worthily finished and seen through the press by Miss Lucy B. Moore. It is thirty-six years since the last comprehensive descriptive account of New Zealand plants was published by F. T. Cheeseman, and in that period collectors and investigators have been most active in the study of the flora. Dr Allan played a leading part in these researches and in field-work, and his wealth of knowledge of plants, botanical literature and the classic collections preserved in Britain equipped him admirably for the forbidding exercise of preparing a new Flora.

Students of the vegetation of New Zealand are well aware of the problems of unusual taxonomic complexity with which the flora of the country bristles. In many groups delimitation of acceptable taxa is notoriously difficult because of the high degree of polymorphy and the prevalence of natural hybridity. There is a wide range of habitats, and the comparatively small area of New Zealand has developed an extraordinary concentration of critical genera. Possibly, as has been suggested in the case of the north-temperate flora, some disturbance of the genetical balance during glacial periods has led to the intense and critical diversification which poses the multitude of taxonomic problems. Most informative, adequately referenced, supplementary notes throughout the work add greatly to its value and assist the reader to gain a better understanding of the many specific and generic complexities.

There is still ample scope for research, and Dr Allan's work reveals most pertinently the many challenging features of the New Zealand flora. Within the compass of little more than a thousand pages he has produced a concise, convenient and eminently satisfactory Flora which will be of immense help in identifying New Zealand plants. Many beautiful New Zealand species have enriched gardens in other parts of the world, and horticulturists will certainly welcome this informative and valuable work.

There is an excellent chronological bibliography and, throughout, copious references are given to relevant literature. This is a work thoroughly to be recommended to all interested in the New Zealand flora—indeed, it is an indispensable tool.

George Taylor

SAMPLING AND ANALYSIS OF COMBUSTION PRODUCTS

Gas Sampling and Chemical Analysis in Combustion Processes

By Prof. G. Tiné. (AGARDograph No. 47.) Pp. xv+94. (London and New York: Pergamon Press, 1961. Published for and on behalf of Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization.) 42s. net.

This latest AGARDograph is devoted to a review of the experimental technique which forms its title, with particular reference to combustion phenomena of aeronautical interest. A proper appreciation of this subject involves a full understanding of many aspects of chemistry, aerodynamics and heat transfer, and it is rare to find an author with an equally detailed acquaintance of all three branches of science. It is clear from the introduction (Section *A*, 3 pages) that Prof. Tiné is well aware of the great importance of chemical phenomena in combustion processes but from the remainder of the book it is apparent that this is not where his own interests lie and that he is much more at home when discussing sampling (Section *B*, 53 pages) than he is when describing gas analysis (Section *C*, 31 pages). Indeed in the conclusion (Section *D*, 1 page), Prof Tiné points out that "if sampling procedures were absolutely reliable, chemical analysis would raise no problem at all". This, in the reviewer's opinion, epitomizes one of the principal weaknesses in what is otherwise a useful and well-constructed book The author gives the impression that chemical analysis is essentially straightforward and easy and thus—to quote but one example of this point of view—we read on p. 69 that "qualitative and quantitative analysis of alcohols and ethers is exhaustively described in most analytical textbooks", a statement that would surprise many expert analysts The section on sampling, however, gives a masterly account of the various difficulties encountered in obtaining representative gas samples; it deals fully with such topics as the disturbance of gas flow by a probe and the problems involved in bringing about rapid quenching

Prof. Tiné has made a noble effort to write a book which attempts to bridge the gaps which always tend to exist between different formal branches of learning It contains a wealth of information, it is well produced and copiously illustrated with diagrams and tables and even if it is in some ways unbalanced in its treatment, it nevertheless provides the most useful and comprehensive treatment of the subject yet produced The price is, however, even on present-day standards, high for a book of this length.

C. F Cullis

THE ENZYMES

The Enzymes

Edited by Paul D Boyer, Henry Lardy and Karl Myrback Vol 2 Purine and Pyrimidine Nucleotides and Phosphagens Prosthetic Groups and Cofactors (Part A) Second edition, completely revised Pp xiii + 479 16 dollars

Vol. 3 Prosthetic Groups and Cofactors (Part B) Pp. xiv + 497 16 dollars

Vol. 4 Hydrolytic Cleavage (Part A) Second edition, completely revised Pp xx + 631 18 dollars. (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1960)

THE second edition of *The Enzymes* is now expected to run to seven volumes, compared with the four volumes of the original edition prepared by Sumner and Myrback. Volume 1, on general principles, has already been reviewed in this journal (*Nature*, 184, 1759, 1959). Volumes 2 and 3 cover nucleotides, phosphagens, prosthetic groups and cofactors, and the chapters are numbered consecutively through these two volumes, since it was originally intended that this material should be covered in a single volume Volume 4 is the first part of a survey of enzymes involved in hydrolytic cleavage; in this case also it has been necessary to extend to two volumes the treatment of a topic originally expected to occupy only one These changes are sufficient evidence of the wealth of material available to the editors, and of the appropriateness of a new edition at this time

At the end of Volume 3 is a chapter on "Enzymic Equilibria and Thermodynamics" which belongs to Volume 1, but was unfortunately delayed by Prof. Johnson's illness A chapter of this kind, discussing basic ideas of equilibria, free-energy changes, pK's, binding constants, and so on, is extremely valuable to the biochemist with little training in physical chemistry who wishes to understand the more quantitative work in the field of enzymology. On the whole this chapter succeeds in its purpose, although in places the treatment is perhaps too elementary, especially compared with the level of many of the chapters in Volume 1 For example, the importance of the *activity* of reactants in thermodynamic calculations might usefully have been stressed

The subject-matter of Volumes 2 and 3 is primarily chemical rather than enzymological There is a chapter each on nucleotides containing adenine, uridine, cytidine, and guanosine and inosine, and one on *N*-phosphorylated guanidines The remaining 15 chapters come under the general heading "Prosthetic Groups and Cofactors", and include chapters on pyridoxal phosphate, folic acid, glutathione, flavins, coenzyme A, pyridine coenzymes, and lipoic acid, as well as a chapter on metal-enzyme interactions and four chapters on vitamins The emphasis varies considerably from chapter to chapter, although it must be admitted that this may be due to the information available as well as to the idiosyncrasies of the authors (It should be noted here that, as in the earlier volumes of *The Enzymes*, each chapter is written by a different expert) The article on adenine nucleotides and pyrophosphate compounds by R. M Bock is a useful general review of the main groups of enzymes acting on adenosine triphosphate, and a discussion of some of the mechanisms involved; those on uridine nucleotides by L F Leloir and C E Cardini, on cytidine nucleotides by E P Kennedy, and on guanosine and inosine nucleotides by M F Utter are largely metabolic, stressing the enzyme systems through which biosynthesis is brought about by these nucleotides On the other hand, the articles on the pyridine coenzymes by N O Kaplan and on thiamine coenzymes by D E Metzler contain a much larger proportion of the pure chemistry of these compounds

Two chapters seem to me to be of particular importance since they survey fields in which there is a good deal of recent work, and which are clearly ripe for an authoritative treatment The first of these is on folic acid, which is excellently covered in 68 pages by J C Rabinowitz. The rather complicated chemistry is first set out, and then the main biochemical functions of folate derivatives are considered in turn purine biosynthesis, serine biosynthesis, methyl group biosynthesis, and the metabolism of various amino-acids Finally, the metabolism of folic acid itself is discussed. The other chapter referred to, by L Jaenicke and F. Lynen, is on coenzyme *A*, and contains nearly 100 pages This is particularly authoritative, since Lynen has himself been responsible for so much of the work which has made clear the metabolic importance of this compound The chapter finishes with a useful table of 63 enzymes requiring coenzyme A or its derivatives Another useful table is that given by A E Braunstein of enzymes requiring pyridoxal phosphate

In view of the obvious pressure on space in this new edition, it seems doubtful whether it was necessary to include in Volume 3 separate chapters on vitamin K, vitamin E, ascorbic acid, and the visual cycle. The role of vitamins K and E in oxidative phosphorylation is still a matter of some uncertainty and speculation, and cannot yet be discussed in terms of known enzymes. The chapter on ascorbic acid does in fact contain a good deal of enzymology, but treats the metabolism of the compound rather than its coenzyme function, which is not known

Volume 4 of the present series is the first of three in which the main groups of enzymes and a number of individual enzymes will be surveyed It deals with enzymes hydrolysing peptide, glycosidic and ester bonds. The chapters are arranged in groups, in each of which the first chapter is a survey of the field covered by those following In the volume under discussion the 'survey' chapters are. "Peptide Bond Cleavage", by Emil Smith, "Other C–N Bond Hydrolyses", by J E Varner, "Cleavage of *O*- and *S*-glycosidic Bonds", by E. H Fischer and E. A. Stein, and "Carboxyl Ester Cleavage", by D K. Myers This arrangement helps greatly to unify what might otherwise be merely a series of disconnected monographs. There is some evidence, too, of editorial efforts to avoid overlap between the chapters

The general standard of this volume is very high, although inevitably the time taken to assemble manuscripts and produce such a volume has meant that in some cases recent developments are not included and the articles are somewhat out of date Most of them, however, will probably remain authoritative sources for some time to come It is not possible here to mention many of the 33 chapters, however, some stand out as giving a stimulating account of an enzyme, in which a large body of factual information is critically assembled, and used as the basis for a discussion of the mechanism of the enzymatic catalysis or the metabolic importance of the enzyme Such chapters are useful reading for all enzymologists, whether or not their own work is connected with the enzymes under discussion They include those on chymotrypsin and trypsin by P. Desnuelle; papain by E L Smith and J R. Kimmel, α-amylases by D. French; β-galactosidases by K Wallenfals and O. P. Malhotra; and acetylcholinesterase by I R Wilson

The Enzymes is well printed on pleasant paper, and the volumes are strongly bound and are not unpleasantly large to handle The whole work is too large to be regarded as a text-book, but as a reference book it should be on the shelves of every biochemist whose activities demand a reasonable knowledge of enzymology Edwin C Webb

IDENTIFICATION, PROPERTIES AND USES OF INDIAN TIMBERS

Indian Woods

Their Identification, Properties and Uses By Dr K. A. Chowdhury and S. S. Ghosh. With the assistance of K Ramesh Rao and S K. Purkayastha Vol. 1· Dilleniaceae to Elaeocarpaceae Pp liii+304+30 plates (Delhi Manager of Publications, 1958) Rs. 25 50 n p., 39*s*

The publication of a new reference book on Indian timbers is a notable event, for Gamble's *Manual of Indian Timbers* (1922) is now out of date and the more recent *Commercial Timbers of India* (1932) by Pearson and Brown omits many of the timbers that are now being exploited commercially. The volume under review is the first of a series of six each dealing with the wood of 250–300 tree species that occur in the Indian sub-continent and are represented in the wood collection at the Forest Research Institute at Dehra Dun. The chief purpose of the book is to enable the timbers to be identified by characters that are to be seen with the naked eye or hand lens, and to assess the working qualities of the woods from their structural and physical properties Brief notes on the habit and distribution of the species are given, together with some particulars of their strength, seasoning properties, durability, working qualities, supplies and uses The descriptions of the woods are illustrated by photographs (× 10) of transverse sections. These illustrations, which are of excellent quality and well reproduced, add considerably to the value of the book The scientific names and the trade and common names are given in separate indexes and there are appendixes dealing in tabular form with the nomenclature of species, classification of the woods by uses and by anatomical structure respectively

After a valuable introduction of 53 pages, the main part of the book consists of descriptions of the woods under the botanical families to which they belong For the sequence of families the authors have used the modified form of the Bentham and Hooker system adopted by Metcalfe and Chalk in *Anatomy of the Dicotyledons* The volume now under review covers 20 families ranging from the Dilleniaceae to the Elaeocarpaceae and includes the important timber-yielding Dipterocarpaceae, more than 70 pages being devoted to this one family. At the end of each family there is an extensive bibliography

The authors are at pains to dispel the popular conception that India is the potential source of large supplies of many diverse timbers They emphasize that the number of timbers available in large quantities is not more than sixty or so, the most important being teak (*Tectona*), sal (*Shorea robusta*) and deodar (*Cedrus deodara*). Before 1939 the number of timbers handled commercially was 300–350, but about 500 were in use during the Second World War Now the local exploitation of relatively unknown woods is becoming more common owing to the increased demand for timber resulting from industrial expansion and to the difficulties of transport

In discussing the general question of how far wood structure can serve as an aid in taxonomy, the authors, in my opinion, take a somewhat pessimistic view. It is quite true, as the authors point out that in many families the individual species, and sometimes the genera, are not easy to separate on the basis of wood structure This, however, does not exclude the possibility of using wood characters for diagnostic purposes, and they are often valuable in determining the correct family relationships of genera the taxonomic position of which is uncertain from exomorphic characters alone The great danger in the study of systematic anatomy is to rely too exclusively on wood characters alone without taking the histology of the rest of the plant into consideration

The authors are to be congratulated on having produced the first volume of a most valuable book which cannot fail to be welcomed by botanists, foresters and wood technologists, and the publication of further parts will be eagerly awaited. It is a matter for regret that the quality of the binding does not do justice to a reference book of such undoubted importance C R Metcalfe

Introduction à l'Electrodynamique Quantique

Par Prof Daniel Kastler (Travaux et Recherches Mathematiques) Pp xxxiii + 333 (Paris Dunod, 1961) 68 N F

THIS remarkable monograph has been written with the highly commendable aim of providing a common understanding between physicists and mathematicians, so far as the elements of quantum field theory are concerned Whether this purpose has been achieved will probably be answered on the basis of the individual taste of any prospective reader The present reviewer feels that the book will prove stimulating for the highly trained theoretical physicist, provided he has already acquired a fairly comprehensive familiarity with the customary formulation of quantum field theory.

The first two chapters and Appendixes *A*, *B*, *C* provide the general mathematical tools and notions vector-spaces, Hilbert space theory, the Lorentz group and its representations, tensor- and spinor-calculus A short chapter on the method of second quantization precedes the classical and quantized theory of the scalar Klein–Gordon field, Maxwell field and Dirac field (Chapters 4–9) Chapter 10 is devoted to a general discussion of the coupled Maxwell and Dirac fields, and the next chapter surveys briefly the formalism of interacting fields in general, including the *S*-matrix theory (The relationship between the *S*-matrix and scattering cross-sections is established in Appendix *D*) Chapters 12–14 show, by examples of Compton scattering, Möller scattering and pair annihilation the applications of the theory The Dyson–Feynman technique and diagrams are discussed only in the next chapter The book concludes with a review of external field problems

The mathematical exposition is 'high-brow' and follows the pattern of best French tradition, but most physicists will probably find it difficult to rediscover within this work the familiar physical concepts they are looking for P ROMAN

Moon Atlas

By V A Firsoff Pp 32 + 7 plates + 2 fold-out maps (London Hutchinson and Co (Publishers), Ltd , 1961) 63*s* net

THE descriptive classification of lunar surface features to be found at the beginning of this atlas is a commendably lucid account of the intricacies of lunar topography Unfortunately, the illustrations appearing later in this atlas do little justice to the lunar photographs now available The four quadrant maps of the lunar surface, although artistically drawn, have the annoying property of including very few names, identifications have to be made via co-ordinates of individual craters Page 22 consists of a very handsome set of photographs of progressive lunar phases but of restricted value The relief map of the Moon, extremely ingeniously drawn, is of value to young astronomers with small telescopes. it is doubtful, however, whether these persons will be able to afford the cost of the atlas The spherical projection photographs add little value to the atlas although there are few such photographs available elsewhere, Firsoff's efforts have not succeeded in producing pictures of sufficiently good quality to contribute much to selenological thought There are good reproductions of the Full Moon, the Moon's averted hemisphere, and the well-known Palomar Observatory Clavius photograph It is misleading that these latter should be included in the section on spherical projection photographs The *Moon Atlas* closes with Firsoff's personal map of the lunar grid system The presentation (in three colours) of this chart leaves something to be desired and I personally prefer to use the small-scale reproduction appearing on the back of the dust cover BRIAN WARNER

The International Dictionary of Physics and Electronics

Second edition Pp. iv + 1355 (Princeton, N J ; D Van Nostrand Company, Ltd., 1961) 27 85 dollars, 205*s*

THE standardization of terminology in physics and electronics is not an attractive task Some national and international bodies have tackled parts of it with fair success, but because they seek agreement between organizations with widely differing experience and outlook, their progress is often slow This comprehensive dictionary, the work of a handful of scientists with an overwhelmingly academic background, is therefore very welcome, even though one can find some unevenness and lack of balance—most likely attributable to the speed of compilation—and some failure to draw sufficiently directly on the works of the established standardization bodies

Three features distinguish the second edition of the dictionary from the first, published in 1956 First, a new introduction shows how classical physics retreated before experimental findings of the early twentieth century and how new theories filled the gaps created, parts of the old introduction, on units and dimensions, are retained under appropriate headings in the body of the book Secondly, the inclusion of many new items lengthens the book by about 200 pages and, thirdly, multilingual indexes (in French, German, Spanish and Russian) are added.

The title 'Dictionary' understates the value of the book for some entries would fully satisfy, and many partially satisfy, the title 'Encyclopædia', the book is therefore educational as well as one of reference The next edition will have many new fields to cover, such as the properties of space, lasers and the applications of low-temperature physics, if it must accordingly increase in size, might not a shorter or concise edition, prepared by cutting the length rather than the number of entries, find a market as well ? J R TILLMAN

The International Zoo Year Book

Vol. 1, 1959 Pp vii + 160 19 plates. Edited by Dr Desmond Morris and Caroline Jarvis (London. Zoological Society of London, 1960) 40*s*

THE International Zoo Year Book fulfils a very long-needed want, but I feel it would be a great advantage if some check or verification could be made on the information given with regard to zoos—particularly in the Reference Section To my knowledge there are many inaccuracies, especially with regard to details concerning the smaller zoos This is my only criticism—otherwise I think the book is a very worth-while effort which will prove of great benefit to all zoological gardens

It is a great advantage to have a list of the senior staff of the zoos of the world, together with their addresses, and also the various departments of zoology The London Zoological Society should be congratulated on the way this book has been produced G S MOTTERSHEAD

THE BETTER USE OF THE WORLD'S FAUNA FOR FOOD

THAT a large proportion of the world's population, especially in the technologically under-developed countries, suffers from either chronic or seasonal under-nutrition is well known. In many of these countries there is a continuous shortage of dietary calories, the ultimate effect of which is to slow down most human activities, with the apparent exception of the rate of reproduction. Not less serious than calorie shortage in its effect on the younger groups of the population and on pregnant and lactating women is the acute deficiency of dietary protein, which may occur with or without a calorie shortage, and is most obvious in its effects on the post-weaning child up to the age of about five years. Such protein deficiency is particularly marked in animal protein, usually richer in the amino-acids essential for growth and usually accompanied by a more valuable assortment of mineral salts, trace elements and vitamins than is vegetable protein.

The Freedom from Hunger Campaign of the Food and Agriculture Organization has as its objectives the improvement in quality as well as in quantity of food consumed in the existing hungry countries. It was therefore a most timely effort of the Institute of Biology to arrange a symposium, held during October 27–28 in the Royal Geographical Society's rooms, on "The Better Use of the World's Fauna for Food".

In the opening session, under Sir Julian Huxley's chairmanship, Dr. Francis Aylward (Borough Polytechnic, London), who has fairly recently returned from an extensive nutritional mission for the Food and Agriculture Organization in one of the under-developed countries, discussed the methods of assessment: (1) of protein requirements of individuals and communities, (2) of protein supplies actually available in a country, (3) of protein deficits on a regional, national and world-wide basis. The available statistical evidence of protein deficits, though not always as accurate as one could wish, was sufficiently convincing, apart from the additional evidence afforded by direct observations, by morbidity records and by mortality statistics. Though it was highly desirable to remove some of the uncertainty regarding the quality of the statistics and for further research on physiological requirements to be carried out, the need was even more urgent to use the scientific and technical knowledge now available in an intensive effort to improve indigenous protein supplies by the adoption of a more vigorous agricultural policy (in the widest sense, to include animal husbandry, fisheries and controlled utilization of wild fauna) and also by a more thorough application of modern food science to conservation and distribution of food.

"The Relative Merits of Plant and Animal Proteins" was the title of the paper given by Dr. A. E. Bender, whose important work on the assessment of the nutritional value of proteins and mixtures of proteins is well known to British nutritionists. Dr. Bender's contribution provided a useful epitome of the methods by which an assessment may be made of the comparative dietary values of different individual proteins, or mixtures of proteins. He related the figures obtained to needs at different ages and in different physiological conditions. The proteins of cassava, plantain, breadfruit and sweet potatoes are inadequate for health of child or adult, those of rice, yams, millet and wheat can maintain the adult, but not the adolescent or the child. Some seed proteins, especially those of legume seeds (and particularly if two or more 'oil-seed' proteins, freed from oil, are mixed), will provide an adequate protein supply for all ages, if they constitute a sufficient proportion of the diet. The advantages and disadvantages of plant and animal proteins were compared, plant proteins being usually the cheaper, with a bigger yield per acre than animal proteins, recent attempts have been made to produce a cheap high-protein food mainly or even exclusively from vegetable sources (for example, 'Incaparina' in Central America). A mixture of animal with a poorer vegetable protein often gave a protein utilization result for the mixture almost as high as if the whole had been animal protein.

Religious prejudices in certain countries—not always under-developed countries—and local taboos more frequently handicapped the consumption of animal than of vegetable protein-rich foods, but the former were, for most people, tastier and more acceptable.

Though the answer to the protein-shortage problem in some countries might be intelligent vegetarianism, yet the advantages for the agricultural productivity of land of mixed farming, and the importance especially to the vulnerable groups of the population of having in the diet a reasonable percentage of protein food from animal sources, could not be overlooked.

Mr. T. J. Lansbury, in discussing potentialities of animal and particularly ruminant husbandry in West Africa, described the existing handicaps of absence of enclosure and of any intelligible system of land tenure, of 'night kraaling' with its consequent decrease in live-weight gain, of disease and particularly of the presence of tsetse fly in many of the wooded areas, of unfertilized, mineral-poor pasture and semi-starvation of stock during long periods of drought, of catastrophic overstocking where cattle and even sheep and goats were regarded more as status symbols than as sources of food, being associated with bride price, ceremonial gifts and ritual sacrifice at traditional ceremonies.

The local cattle were nevertheless capable of good growth and production if adequate and controlled water supplies and the provision of dry-season supplementary foods could be organized. Two indigenous breeds of cattle, the n'dama and the West African dwarf shorthorn had considerable resistance to trypanosomiasis and were being introduced with advantage into certain tsetse-infested areas where well-distributed rainfall gave good grass production. The substitution of nomadic husbandry by mixed farming, enabling pastures to be suitably fertilized and fodder to be conserved for the dry season, entailed formidable sociological problems as well as wide dissemination of improved techniques.

Mr. Lansbury considered that pig and poultry husbandry probably offered fewer difficulties than cattle husbandry and that it should be possible to use modern knowledge to expand the pig and poultry industry rapidly and efficiently in West Africa, with great benefit to human nutrition.

The text of a paper by Prof. A. G. Bannikov, of the Academy of Veterinary Sciences, Moscow, on the exploitation of the saiga antelope in the U S S R had been circulated, but unfortunately had to be discussed in the author's unexpected absence.

This antelope, which now occurs in increasing numbers in both European and Asiatic U S S.R territories, was in the 1920's, as the result of uncontrolled, destructive hunting, almost extinct Protective laws, introduced in 1919, intended merely to preserve the remnants of the species as a rare curiosity, had little effect at first, but in the 1930's and 1940's a rapid increase in numbers became evident and to-day the total saiga population in Europe is about 500,000, and in Asiatic U S S R about 1,500,000, mainly in the steppe plains and semi-deserts It is a fertile ruminant, congregates in large and mobile herds and is now being systematically and rationally hunted, usually at night by organized groups of marksmen equipped with motor-vehicles with powerful headlights which attract the antelopes Prof Bannikov stated that the recovery of the saiga from near extinction to profitability is a vindication of the principles of intelligent nature conservation

The use of an entirely different genus of animal for food was recorded by Dr R Orraca-Tetteh, who described the habits, collection and utilization in the diet of the giant African snail, *Achatina*

Achatina, the largest living land mollusc, with, it was stated, a foot which when fully expanded might reach 30 cm in length, is found in different parts of Africa, south of the Sahara During the rainy season the snail population in the forests is often large. The animals are particularly active at night, browsing on tender leaves and fallen fruit, and growing rapidly They are collected usually before sunrise and sent quickly to the market They are killed by dropping snail and shell into hot water, the molluscs are then removed by hand They may be eaten at once in soup or stew, or preserved for three months or more by smoking The fresh samples contain about 16 per cent of protein, with a small amount of fat, some thiamine, riboflavin and niacin, and more than 70 per cent of moisture, the protein has a high content of lysine.

In parts of West Africa the snail is a very popular article of diet, and can be purchased cheaply during the rainy season

Dr L Harrison Matthews discussed the problems and potentialities of wild-game ranching, which appears to be increasing, in Africa The existing species of wild vegetivorous fauna in large areas in Africa have been established there long enough to become adjusted to their environment, making use of all the food resources, some by grazing, others browsing, others by eating the upper leaves of trees The bio-mass of this wild fauna which is commercially exploitable is large, especially if natural predators are kept in check

Most cattle ranchers coming into these areas in the past have destroyed or driven away the wild ungulates, regarding them as pests, though the cattle brought in have made less-efficient use of the vegetable food available

The deliberate ranching of mixed wild fauna if they can be profitably cropped for human food is a commercial possibility that is now being exploited with some success In Southern Rhodesia it is said to be more profitable than cattle ranching, while in the Republic of South Africa between 2,000 and 3,000 farmers are said to be stocking game, including such animals as zebra, wildebeest, impala, eland, kudu The resistance of these animals to disease is greater than that of imported cattle Transport and marketing problems in the sale of meat and hides are being solved It was thought that once game ranching becomes commercially established, the extinction of the wild fauna concerned will be unlikely.

Efficient food processing preserves the nutritive value of the raw materials and yields a product acceptable to the consumer P L Pellet and D. S Millar, of the London School of Hygiene and Tropical Medicine, considered the processing and preservation of meat in under-developed areas from both these points of view. In tropical environments the slaughter of stock and the production of dressed carcasses either for immediate consumption or for preservation are fraught with temperature, and other, hazzrds Further, the particular, and to Western eyes rather peculiar, food preferences of the local consumers have to be taken into account, for example, "To the Ghanian, the eating of, or rather the chewing of, meat is a pleasure to be taken leisurely, and consequently he regards tender flesh as low in value" Methods of preservation can seriously lower the nutritive value of any kind of meat or fish, but traditional preserved meats such as biltong, charqui, pemmican and kavurma are highly acceptable to the local consumers, and often showed little protein damage. If traditional methods of preservation were studied scientifically, many could be extended with advantage to meet the immediate protein needs of populations of under-developed countries More sophisticated, modern methods such as refrigeration, canning, dehydration, vacuum contact drying, vacuum oil dehydration, production of meat powders, with the modern equipment necessary could be brought in as capital resources increased and indigenous food preferences and habits permitted

The waters of the Earth (seas, lakes and rivers) occupy 75 per cent of its surface, but account for only 10 per cent of the world's food supply The second day of the symposium was devoted to the problem of increasing food supplies from these sources. Mr E B Parrish (Department of Agriculture and Fisheries for Scotland, Aberdeen) introduced the complex question of how to obtain maximum yield from traditional methods of fishing The increasing intensity of fishing in certain areas such as the North Sea and north-west Atlantic has led to a decrease in the size and age of the fish caught and to a diminution in profitability of fishing To prevent 'overfishing' of these areas, international conventions have been arrived at "for the investigation, protection and conservation of the fisheries" in order to make possible the maintenance of a "maximum sustained catch" Regulations for the fixing of catch quotas, for closed seasons, for closed fishing areas, for controlling the size at which fish could be caught by the fishing gear, for fixing of minimum landing-size limits, have been tried with mixed success

In the conservation and management of fisheries large demands are made on scientific methods of investigating the population dynamics of the exploited fish stocks, these demands continue after regulations have been put into practice, to assess the responses of the exploited stock to them and give more precise adjustments of present fishing intensity to the maintenance of adequate future fish supplies.

Mr F D Ommanney gave a fascinating account of sea fisheries in tropical areas The poor gear and low status of the average tropical fisherman are slowly improving and in British dependent territories the work of fishery officers has led to major advances, largely a result of fitting fishing boats with engines—outboard for the smaller and inboard for the larger craft, and partly by improved nets. At the same time, attempts have been and are being made, as a result of increased landings of fish, to reduce the price to the consumer.

Some Governments in British dependent territories or those formerly dependent, have provided special fishing vessels for exploratory and pioneering work. Stations for fisheries investigations have been established in a few tropical countries, but owing to the vagaries of Government support have not been entirely successful. For the progress of tropical fisheries and the optimal use, in protein-hungry, maritime countries, of sea fauna for food, active and adequately supported research stations are urgently needed.

Improvements and trends of development in marine fishing methods and gear were the subject of a technical, well-illustrated contribution from Dr. J. Scharfe, of the Food and Agriculture Organization (Rome). Fish location and detection have been aided by aerial scouting and still more by fish-finding echo sounders and rangers. These need much skill and practical experience to use to full advantage. This technique is now firmly established for all medium and large fishing vessels in the developed countries. Synthetic fibres stronger and more elastic than natural fibres are being used very widely for nets and lines, and have inspired new ideas in the design and operation of fishing gear and methods.

Larger stern-trawlers of up to 3,000 h.p. with freezers, cold storage and in some cases manufacturing plant for oil and fish meal can now go quickly to distant grounds and remain away from home ports for extended periods. Fishing fleets exist with boats specialized for searching, catching, factory work, transport, hospital and recreation facilities. Mid-water trawling with echo sounding is a modern line of development which is likely to have far-reaching results.

Electrical killing or stunning of fish in confined waters has been experimented with with some success and may have a future even for sea fish.

Mr. K. F. Vaas, of Yerseke (Netherlands), pointed out that fish culture in freshwater and brackish ponds was both an ancient and a very widespread craft. *Tilapia* was cultivated in ponds in Egypt before 2,000 B.C., and a text-book on fish culture was written in China in 475 B.C. Large yields of fish per acre of water surface are obtainable under favourable conditions—the Grand Lac in Cambodia with an area at high water of 10,000 km.^{2} is said to produce 100 kgm. fish per hectare.

Tropical ponds give better yields than those of colder climates, but much depends on 'management' in the shape of fertilizers or the introduction of fish foods of various kinds. Fish culture may be combined with animal husbandry, the dung fertilizing the growth in the ponds of fish food such as diatoms, plants and crustaceans. Production of fish from inland waters has been calculated to be some 18 per cent of the total world catch.

The culture of marine molluscs and crustaceans was reported on by P. R. Walne, of the Ministry of Agriculture, Food and Fisheries, Fisheries Experiment Station, Conway. In the United Kingdom, shellfish form only 2·5 per cent, in Japan 19 per cent, in the Netherlands 28 per cent, and, rather surprisingly, in the United States 30 per cent of the total fish landings. Oysters and mussels are slow growing, the mussel requiring four years, and the oyster five, to reach marketable size. The meat of the adult oyster or mussel contains some 80 per cent of water and 9–13 per cent of protein, that is, roughly 50 per cent or more of protein on the dry weight. Oysters are probably the most carefully cultivated crop obtainable from the sea. In recent years mechanical methods, including special dredges, are being used for removal of the bivalves to new grounds from time to time, and for final harvesting. Such dredges attached to power-driven boats can work economically on quite low population densities. By this means both the mussel and the oyster stock in Holland is moved several times to assist growth and reduce starfish depredation.

Mr. Walne considered that an important future step in oyster husbandry should be what has been done with practically all agricultural plants and animals, namely, to increase the rate of growth and quality of the stock by breeding and selection.

Some recent advances in the processing of fish were described by Dr. D. L. Nichol, of the Department of Scientific and Industrial Research, Humber Laboratory, Hull, in relation to the more efficient use of this source of food.

'White' fish gutted, washed and stored in ice at sea become stale after 12–15 days, and if distant water voyages are to last longer than the average of 18–20 days (4 days each way to the fishing grounds) apparatus is needed for deep freezing at sea at least part of the catch. In trials carried out in 1956, this method of preservation of whole fish has been proved successful and more trawlers are being fitted out with the necessary deep-freeze equipment.

Deep-frozen fish is now being distributed in various forms to consumers. It is necessary to keep the temperature down all along the distribution chain, and this is not always realized, as the difference between a block of frozen fish at − 20° F. (a temperature at which no deterioration occurs in eight months) and + 20° F. (a temperature at which deterioration occurs within a month) is not obvious to the operator.

Herring processing presents different problems from that of white fish, as herring fishing is seasonal and the disposal of gluts may arise. Gluts of herrings are usually transformed into oil and fish meal, the latter being utilized in the manufacture of animal feeding stuffs and increasingly in tinned food for domestic pets.

White fish meal prepared from surplus or condemned fish and from fish offal is manufactured in the United Kingdom and abroad in substantial quantities for use in animal feeding stuffs. Fish flour, a deodorized and almost flavourless powder usually made from whole fish, is proving acceptable as an addition to human diet in certain protein-deficient regions.

A paper on the possible farming of the sea from Sir Alister Hardy concluded the symposium. He discussed the possibility of improving the production of plankton and hence of the fish that ultimately depend on plankton for food either by fertilization of limited or confined areas of sea with phosphates and nitrogen or by causing up-welling of the deeper layers of sea-water which are richer in nutritive salts than the upper layers. He also mentioned methods for diminishing the enormous loss of fish that occurs in early life and the possible transporting of young fish from crowded to less-crowded areas.

Recent research has shown that invertebrate competitors of fish on the sea bed, such as starfish, are much more important in limiting the potential supply of food available to fish than was formerly realized, and that at least in limited areas such pests might be greatly reduced in numbers by specialized trawling

To summarize, the following are among the main considerations that emerged from the symposium

(1) The rapid rise in world population makes it doubly important that there should be increased production and much better utilization for human food of land fauna, both domestic and wild, and of sea fauna.

(2) The potentialities of such increased production are large if present agricultural, animal husbandry and fisheries knowledge is effectively applied, and if the utilization of wild animals is conducted intelligently and under adequate control, these potentialities are immense if sufficient research effort is directed towards the further acquisition of knowledge in these fields, particularly in that of marine biology

(3) The rate of progress in improving the protein status of malnourished populations will depend largely on indigenous decisions to correlate their farming and their fisheries policy with indigenous nutritional needs, and actively and continuously to stimulate the intelligent knowledgeable local production of fish, flesh and fowl

The proceedings of the symposium will be published by the Institute of Biology (41 Queen's Gate, London, S W 7) H D Kay

FIFTH INTERNATIONAL CONGRESS OF BIOCHEMISTRY

The fifth International Congress of Biochemistry, organized by the U S S R Biochemical Society and sponsored by the International Union of Biochemistry and the Academy of Science of the U S S R, was held in Moscow during August 10–16, under the presidency of Academician A I Oparin The scientific sessions were held in the imposing building of the University of Moscow which stands on the Lenin Hills and overlooks the historic city The number of registered participants, about 4,500 together with an additional 1,000 or so guests of the Organizing Committee, was larger than any previous congress, and it seems that each congress, from the first, which was held in Cambridge in 1949, to the present one in Moscow, attracts more and more workers who are interested in one or many aspects of the broad subject of biochemistry

The congress held its opening ceremony in the impressive Palace of Sports of the Central Lenin Stadium and the session closed with a masterly lecture on "The Structure and Function of Sub-cellular Particles", by Prof D E Green (United States) Unfortunately, poor projection facilities reduced the enjoyment of many participants who were not fortunate enough to be seated near the front of the huge lecture hall The plenary session was followed by a most enjoyable concert given by the Moscow Symphony Orchestra

The scientific programme which followed included a series of symposia, and between two and three thousand original contributions given under the auspices of twenty-eight sections The main congress symposia were held in the large assembly hall of the University or in auditoria of ample seating capacity and were well attended throughout The symposia covered the following subjects (1) Biological Structure and Function at the Molecular Level (president, M F Perutz, Great Britain), (2) Functional Biochemistry of Cell Structures (O. Lindberg, Sweden), (3) Evolutionary Biochemistry (S Ochoa, United States), (4) Molecular Basis of Enzyme Action and Inhibition (P Desnuelle, France), (5) Intracellular Respiration Phosphorylating and Non-Phosphorylating Reactions (E C Slater, Holland), (6) Mechanism of Photosynthesis (H Tamiya, Japan); (7) Biosynthesis of Lipids (G Popják, Great Britain), (8) Biochemical Principles of Food Industry (E Pyanowski, Poland) The main speakers in these sessions were allowed up to forty minutes to develop their subject and the subsequent speakers fifteen minutes, a half to three-quarters of an hour being set aside at the end of the session for discussion The time proved to be adequate, and the discussions were usually lively The arrangements for simultaneous translations in these meetings were excellent.

Among the many important communications given in the symposia Dr. Britton Chance's demonstration of a new effect in the field of intracellular respiration predicted on theoretical grounds some years ago by Sir Hans Krebs, namely, the reversal of the direction of electron transfer in isolated mitochondria occurring on the addition of adenosine triphosphate and leading to a reduction of pyridine nucleotide was particularly noteworthy, as were Prof A L. Lehninger's report on a preparation of hitherto unrecognized components of the chain of oxidative phosphorylation and their relation to the swelling and contraction of mitochondria, and Prof Lynen's account of the advances he and his colleagues had recently made in the understanding of the role of (+)-biotin as a coenzyme of carbon dioxide fixation and transcarboxylation Prof E P Kennedy (United States) gave an outstanding lecture on lipid biosynthesis There were, of course, many other new and interesting aspects of fundamental problems presented at the congress, but the author, in common with other participants, was able to hear only a small part of them. Pre-prints of the main congress lectures and of the contributions to the symposia were available to participants before the meeting

Probably the largest part of the scientific programme was associated with the activities of the twenty-eight sections which held their meetings and discussions in nearly as many rooms scattered throughout the very large University building and in the Departments of Physics and of Chemistry situated a few minutes walk from the main building. Two of the Sections, those concerned with Immunochemistry and the Biochemistry of Malignant Tumours, held their meetings in the Sternberg Institute of Astronomy, which was unfortunately about a 15-min walk away from the site of the main congress activities

Each section had its own interpreter, and language difficulties were thereby reduced to a minimum Abstracts of the short communications were available in the form of a separate book, and where the text was submitted in Russian, an English translation was also provided.

A Russian version of the whole of the congress proceedings is to be published by the U.S.S R Academy of Science and a corresponding publication in English (10 vols.) will be made by the Pergamon Press, Ltd These volumes are in course of preparation.

There was a useful display of scientific apparatus originating from fourteen countries, and an attractive exhibition of modern books dealing with all aspects of biochemistry and published in many different countries

A significant achievement, admittedly not directly a part of the congress, was the appearance of the report of the Commission on Enzymes, of the International Union of Biochemistry This document, which is the first official attempt to put enzyme nomenclature on an international basis, is the work of a group of acknowledged experts under the chairmanship of Dr Malcolm Dixon of the University of Cambridge. It makes an outstanding and much-needed contribution to modern enzymology.

Most of those attending the congress were accommodated in the student quarters of the University or in two of the largest hotels in Moscow, Hotel Ukraine and Hotel Mockba The problems which arose through accommodating so many visitors in so short a time were finally sorted out, although only after some participants had suffered considerable inconvenience It was generally agreed, however, that once one had found the accommodation for which one had originally asked, the standard of comfort was all that could be desired Transport between the University and hotels was well maintained throughout the congress by an excellent bus service The hosts were most generous with their hospitality and Academician Oparin gave a series of most delightful receptions to the participants in the symposia There was a series of interesting tours arranged by Intourist.

The participants from the Commonwealth much appreciated the kindness of Sir Frank Roberts, the British Ambassador in the U S S R , who held a reception so that British participants might entertain their Russian colleagues who had given so much time and made so much effort to make the congress the scientific success it undoubtedly was

Plans for the next international congress are by now under serious consideration, and it must be in the minds of the organizers that it will be attended by an even greater number of scientists than were present in Moscow this year It is clearly impossible for any one person to attend more than a few of the sessions, and it is also evident that ten minutes for the presentation and discussion of each ordinary communication is inadequate It might, therefore, be worth considering whether a more satisfactory procedure for use at future congresses would be to restrict the number of speakers, without limiting the number of papers communicated by title and circulated in the form of abstracts A limitation of this kind would also reduce the number of simultaneous sessions, which, it is generally agreed, are far too many at large international congresses in which there are only four or five days to present and discuss all the papers submitted by the participants

Perhaps to-day the long notice required to publish and pre-circulate abstracts of the scientific contributions makes it unlikely that anything really new will be announced at an international congress Probably the most valuable function of such a meeting is to bring workers together to take part in symposia and to engage in informal discussion, where they can estimate their progress or thrash out their differences or misunderstandings in small rooms or quiet corners which are set apart for such gatherings, but which are within easy reach of the main meeting rooms and where light refreshments would be available.

The fifth International Congress in Biochemistry was the largest congress yet held in the U S S R and it was obviously well supported by the Russian Government It is generally recognized that the more biological aspects of science in the U S S R have up to the present received far less attention than have the physical and engineering sciences, but the impression gained was that there is a growing awareness of this relative neglect, and that there was an awakening to the fact that biochemistry and other biological subjects must in future receive the support they so justly deserve and need

The closing plenary session was especially noteworthy for the outstanding and informative lecture on "Proteins, their Function and Structure" given by Prof F Sorm (Czechoslovakia) This was followed by a number of short addresses of appreciation by delegates from several countries, after which the president closed the proceedings and formally announced that the next congress would be held in New York in July 1964

W T J MORGAN

ATTENTION AND IN-ATTENTION IN NEUROPHYSIOLOGY[*]

By L. GOLDIE[†] and MRS J. M. GREEN

Institute of Psychiatry, Maudsley Hospital, London, S.E 5

RECENT advances in neurophysiological techniques have enabled objective evidence to be readily and reliably obtained during long recordings, and cortical and subcortical electrical events to be examined.

Despite this there has been little increase in the understanding of the working of the human brain as it relates to mental experience Much experimental work in the past has centred on the animal brain Transposition of the theories derived from such studies to the special problem of the human brain has resulted in the formulation of certain philosophical devices to overcome complexities by narrowing the observations within certain controllable limits

But philosophical issues must inevitably be subjected to the test of practical experiments The Dualists, in supporting a metaphysical theory of reality, regarded the mind as having an independent existence, and since this was considered to be beyond the reach of natural science discounted it in formal experiments. The psycho-physicists, exemplified by Fechner did much the same thing when they narrowed the limits of their experiments by attempting to exclude the effects of subjective factors, and then concentrated on the properties of the stimulus which they expressed in terms of mathematical formulæ. Pavlov went even further and chose to disregard the subjective factor altogether, assuming physiology to be a sufficient explanation of the mind. Psychophysical parallelism, on the other hand, while acknowledging essentially human manifestations to be accompaniments of physical activity in the brain, considered them to vary concomitantly without one affecting the other and therefore to be outside the scope of experimental method

---

[*] Substance of a paper read at the Ninth Latin American Congress of Neurosurgery during a symposium on the "Physiological Basis of Mental Activity", October 1961.

[†] Present address The Fountain and Carshalton Group, Queen Mary's Hospital for Children, Carshalton, Surrey

These manœuvres have resulted in any effect of mental life being disregarded, and have led to the emphasis being placed on the physical attributes of stimuli But the problems imposed are the very essence of conscious human being and to simplify them is to destroy the very quality that it is hoped to study Such writers as Helmholtz[1], Wundt[2] and James[3] were not restricted by metaphysical considerations and evinced an open-minded acceptance of the available facts in the context of the fundamental issues raised, discussing them comprehensively and elegantly By the same token Sherrington[4] and Adrian[5] reiterated the unanswered problems impressed on them by their experiments and observations on human subjects. Thus Adrian comments that "though one brain may look like another, what it does in response to a stimulus may be quite different because it depends on all the brain has done since it was first in action" This central problem remains and has become of paramount importance in neurophysiology, where inconsistent results of experiments and some routine findings on human subjects have not been fully explained by a physiological stimulus-response association[6-11].

In this article the attempt has been made to examine aspects of the fundamental psychological processes of attention and apperception, considering also the terminology that may usefully be applied and then to relate these to physiological changes Some common-place phenomena such as may be seen in routine and experimental neurophysiological recordings are considered and used for illustrative purpose to support the suggestion that results, which on superficial examination appear to be random, may be better understood if, when causal analysis is attempted, the mental no less than the physical characteristics of the human subject are accepted and used as data

An elementary instance of this approach is provided by the psychogalvanic skin response, the variation of which in occurrence was apparent during interviews recorded on this unit. (Electrophysiological experiments performed by us utilized two small rooms, one for the patient and one for the apparatus, linked by a one-way screen. The observer in the patient's room was kept informed of events in the instrument room via an intercommunicating system linked to a deaf-aid earpiece The electroencephalogram and appropriate peripheral ancillary recordings were made during interviews The sessions were recorded on magnetic tape and these were correlated with the electroencephalogram, which could also be marked by the observer using a marker-button) It was observed that incidental door bangs from the corridor usually elicited a response in subjects and patients when they were waiting for the observer to enter the room During the interviews, however, though psychogalvanic skin responses were occurring in conversation, they were rarely seen in relation to door bangs (the latency of the response to a known stimulus having been established) When a response did occasionally occur to a door noise, it was found on cursory examination that the interview material usually indicated that at such times the entry of another person (such as an unauthorized person or a nurse with an injection tray) would, for example, have been a frightening or embarrassing possibility Here it appears that the assessment of the physical properties of a stimulus is alone insufficient to account for the behaviour of these responses

The question of adaptation was considered and in the experimental situation when sound and light flash stimuli were repeated for some time without instructions, responses were produced that tended to 'habituate', that is, to decrease and disappear However, when subjects then performed a series of tasks each one commencing when the stimulus sounded, the response was shown to behave differently and to alter with each repetition of the stimulus. These tasks involved mental imagery and concentration, and there were experiments with simple hand or finger movement and variations with touch. From such experiments it appeared that when the physical conditions of an experiment, including the stimulus, remained the same, variations in the response could be causally related to mental activity We are reminded by Adrian[12] that "the method of experiment is to relate the stimulus to the resulting response but this ignores the fact of attention to the stimulus", the crucial consideration in this sense and in our experiments hinges on the meaning of the word 'attention'

When recognizing attention or mental activity one should perhaps first consider the distinction between the external world of objective reality and the reflexion of this in the internal world of psychical reality The description of a stimulus by an observer must necessarily have a limited connexion with the response, for the stimulus occurs in the external world of the subject while the response is related to his internal world The response to the stimulus will therefore be governed by the 'significance' that the stimulus has for the individual subject at any particular moment

In another context this is very obvious when one considers a child reacting with a temper tantrum to something we may think is innocuous In terms of the external world the child's reaction is inappropriate, but the situation as depicted in the inner world of the child may explain the behaviour "In a tantrum the violence of the physical struggle being due to internal changes such that [he] becomes blind and deaf to external reality[13]". This is further illustrated by an experiment of Sharpey-Schafer *et al* [14], who investigated the mechanism of acute hypotension from fear or nausea in a series of patients submitted to anæsthesia for dental operations He demonstrated that in four out of five subjects in whom acute hypotension occurred during the administration of gas, arterial pressure fell before the mask was placed on the face The dental surgeon and anæsthetist did not recognize that severe hypotension was present and were apt to call this state 'a nice quiet gas' The result was therefore attributed to the wrong 'cause' and had tradition not ordained that the patients be lain flat the outcome would have been irreversible. The author comments "It is suggested that emotional stimulation of the heart beat and a fall in cardiac filling pressure caused virtual emptying of a ventricular chamber during systole which fires the afferent mechanism of the faint reflex".

In electrophysiological experiments Hernández Peón[15] recorded the occipital responses to single light flashes using subcortical electrodes and found that the response amplitude became larger with the increased intensity of the light. Keeping the brightness constant he then suggested alterations in intensity and demonstrated that the occipital responses to light flashes showed a greater change in line with suggestions than with objective variations in light intensity. It may be said that subjective factors influenced some facet of 'attention' paid by the patient to the light flashes and this determined the variations in the occipital responses. Hence these reactions can be better comprehended when they are thought of as the result of object relationships in the internal world. This reasoning must also apply in the tantrum and dental situations.

A comparable instance was observed by us[16] during an intensive study of a case of sensory reflex epilepsy. A clear-cut electrical wave-form occurred in the left parietal cortex when the patient rubbed the right side of his face, which was also associated with the production of a fit, and the experiments showed that this could also be effectively produced by psychological means alone. During experimental sessions on this patient it was demonstrated that the electrical response, besides occurring when he rubbed his face, appeared when he made the rubbing movements without touching his face (the patient was hypnotized). It was confirmed statistically that this psychological stimulus was just as effective for the evocation of the wave-form as actual rubbing. The null hypothesis was tested that this response could have happened by chance alone and was shown to be highly improbable. The electrical response also appeared when he anticipated rubbing his face, and it occurred when he was asked to imagine rubbing his face, or when he imagined having a fit; this was demonstrated in the laboratory and while recording directly from the brain exposed at operation. At other times the occurrence of the electrical activity during conversation appeared to be related to certain topics.

Consequent to these findings another sample of recordings was examined to determine the frequency of similar episodes occurring during the resting state when stimuli were not deliberately being given. It was established that during a period of 15 hr. 35 min. recording time, the electrical response appeared only on ten occasions unrelated to any known stimulus, but on forty occasions was temporally related to happenings that had been noted on the record (for example, intermittent noises, including the telephone and people entering the room, etc.). It was then shown that during a much shorter period of 3 hr. 28 min. recording time, under experimental conditions, the response appeared on thirty-five occasions in relation to known psychological stimuli, statistically exceeding anything that could occur by chance alone. These instances show that a causal sequence may be established using data that at first sight appear to be random or spontaneous.

In another experiment performed on the same patient in the hypnotic state an attempt was made to produce an anæsthesia of the right cheek. Loss of sensation was suggested, and when the right face was touched by the observer there was no change in the electroencephalographic record. On another occasion, however, the suggestion was worded differently and the patient was told that the right side of his face was "frozen and insensitive". Contrary to what was expected the electrical response was immediately evident at high amplitude when this area was touched, but did not similarly occur when he was touched elsewhere on the face (Fig. 1). After this session the patient volunteered the information that he had been surprised and impressed to find that his right face had felt intensely cold. It was thus evident that his interpretation of the suggestion had differed from that which had been intended and that he had in effect focused 'attention' on this area of the face instead of away from it. Here the only clue to the unexpected results lies in the information the patient provides regarding his interpretation of the suggestion. It appeared that the factors governing the result included the direction of attention, the exclusion of other matters, and possibly the amount of effort involved in the task.

The evidence presented establishes that a relationship can be demonstrated between mental activity and physiological changes. But to understand something of this problem it is first necessary to examine aspects of the process of attention and then to use descriptive terms that have practical application. William James[3] and Adrian[17] describe attention as consciousness being occupied by one thing at a time, to Sherrington[4] attention was but a further application of the rule that "unlike reflexes have successive but not simultaneous use of the common path. Expressed teleologically, the common path, although economically subservient for many and various purposes, is adapted to serve but one purpose at a time. Hence it is a co-ordinating mechanism and prevents confusion by restricting the use of the organ, its 'minister', to but one action at a time. . . . The resultant singleness of action from moment to moment is a keystone in the construction of the individual whose unity it is the specific office of the nervous system to perfect. The interference of unlike reflexes and the alliance of like reflexes in their action on their common paths seem to lie at the very root of the great psychical process of 'attention'."

The application of attention to one thing at a time necessitates the simultaneous withdrawal of attention from everything else that is not attended to. This is described as 'in-attention', and produces a descriptive hiatus. In an attempt to resolve this difficulty Freud's concept of mental energy[18] is put forward for consideration. "The Pre-conscious has at its disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of 'attention'." This idea of a constant amount of mental energy was first formally proposed by Cabanis[19] "Sensibility seems to behave like a fluid whose total quantity is fixed and which whenever it pours into one of its channels in greater abundance becomes less in others" and it was referred to again by Janet. Using this concept some resolution of the semantic problem is possible. An object engaging our attention could be said to be endowed with a special significance and meaning, and result in a redistribution of cathectic energy. While this energy is focused on one object, there is simultaneously a reduction of energy available for other objects. When an object is weakly cathected, another object may readily sup-

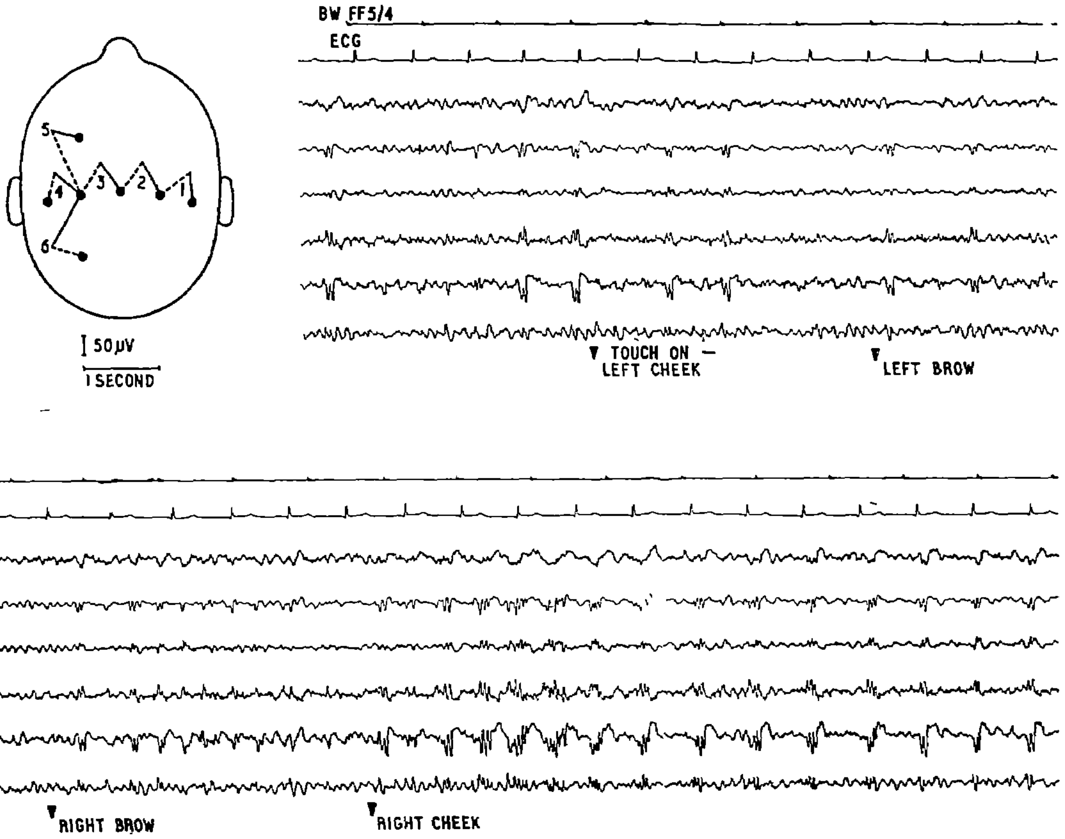

Fig 1 Time constant, 0 1 sec., high frequency, 25 per cent , amplifier sensitivity, 7 mm for 50 μV. input

plant it in common parlance it may then be said that we are 'easily distracted'.

This formulation may be applied to lambda-wave investigations[20], where it was an unequivocal finding that in the majority of control subjects tested, light, eye movement and some facet of psychological 'set' were all necessary for the evocation of lambda-waves in the occipital cortex when looking at a picture It appeared that interest, effort or the focusing of attention in a particular direction were necessary, that is, the picture had to be 'cathected' The problem, however, remains as to whether recorded changes may be due to 'attention' or 'in-attention' or due to the process of redistribution of cathectic energy Adrian[17] in 1934 and afterwards, by his exhaustive examination of the alpha rhythm on himself and his co-workers, makes the consideration of such mental processes inevitable He speaks of closing the eyes with the automatic withdrawal of attention from visual phenomena . . . "we try to see in the dark when the subject does not expect to see anything the rhythm persists" "A problem that contains the whole attention even with the eyes shut will block the rhythm, it will return as soon as the 'attention' wanders". "The rhythm is stopped if the whole attention is involved Perception of light does not affect it perception of pattern or the *attempt* to perceive it does"

Characteristically the alpha rhythm of the human, while varying enormously from subject to subject, when fully developed, remains of constant form for the individual. The phenomenon has much in common with that seen in the water beetle[17], and is presumably connected with basic biological activities necessary for survival, though in human beings the added cerebral organization obscures and complicates the connexion In man, vision is the dominant sense and the only one that can be voluntarily controlled, and it is perhaps not without reason that the alpha rhythm is most easily influenced by the act of opening and closing the eyes It may also be modified by psychological factors, the examination of which inevitably concerns us with the central process of attention Opening the eyes must involve at a primitive level the 'taking in' of visual information from the external world which confirms or denies the possibilities arising as a result of sensory input from other modalities. Similarly, closing the eyes may shut out visual stimuli arriving from the external world but also has the effect of increasing dependence on other sensory information which is interpreted in the light of past experience With such an act these interpretations become prepotent because they now lack the possibility of visual checking with reality. These considerations therefore make it necessary to try to examine the physiological changes in terms of a relationship with the mental counterparts of physical acts This possible relationship was found to occur in the case of sensory reflex epilepsy already described where the mental counterpart of the physical act was shown to be as effective in evoking the electrical response as actual rubbing of the face

That psychological factors can influence the alpha rhythm behaviour may be well illustrated by the occasions of its appearance and non-appearance and its fluctuations, during recorded interviews or silences, when the eyes were kept open or closed The significance or meaning that the situation had for the subject, and also the amount of continued 'force', 'effort', or 'cathectic energy' that was invoked appeared to be but two of the factors that could inhibit the alpha rhythm. This was particularly prominent with visualization.

It was, however, notable that the rhythm could be both evoked or inhibited when speech started or stopped. This was surprising, since one might expect the rhythm to be inhibited on the commencement of conversation and to reappear on its cessation. Furthermore, when it was shown that one subject, who had a sensitive high-amplitude alpha rhythm which was classic in behaviour, was attending closely to a discussion which at one stage involved the description of a biological film, his alpha rhythm continued unabated. Not only was the subject kept deeply involved but when electronic sound stimuli were introduced during the discussion they failed to effect any alteration in the alpha rhythm or to elicit a psychogalvanic skin response within 3 sec. of the stimulus. From these observations and some experiments involving mental tasks which produced inconsistent results it appears then that attention cannot be considered or discussed in psychologically unsophisticated terms.

That mental processes could be related to physiological functions was recognized by Darwin[21] when, for example, he wrote . . . "Blushing is not only voluntary, but the wish to restrain it by leading to self-attention actually increases the tendency" and . . . "the reddening of the face from a blush is due to the relaxation of the muscular coats of the small arteries, by which the capillaries become filled with blood, and this depends on the proper vasomotor centre being affected". Reflecting on the mental state that produces blushing he wrote: "It is not the simple act of reflecting on your own appearance, but the thinking what others think of us which excites the blush". A brief consideration of deceptively simple phenomena therefore yields complexities: paying attention to a person will not of itself produce a blush without the intervention of affective factors. In Darwin's example it may be said that an affective response has been induced by a mental image which is endowed with certain attributes: here the evocative stimulus is not the object in the environment but the feelings we have about it or its supposed intent.

With the above presumptions we may with profit re-examine other situations which remain causally enigmatic. Of the epilepsies, the 'reflex' type is perhaps most pertinent since there is an apparently specific stimulus response association. Apart from the case of sensory reflex epilepsy already quoted it was found in other cases that the causal connexion was not a simple one and that the emotional substrate had to be considered. The clearest demonstration of this was provided by three patients suffering from musicogenic epilepsy where the music alone was shown not to be directly and consistently responsible for the fits. In our experiments the metronome sounds and gramophone-record music alleged by the patients to precipitate fits were presented. Apart from rare occasions when fits occurred, the patients reported that the stimulus had not produced the feeling that occurred when a fit was imminent. Conversely, fits occurred when there was a marked emotional response to the music, and this was often accompanied by an electroencephalographic change. This observation has already been noted by Critchley[22], Shaw and Hill[23] and others. Therefore it can only be the psychological import of the stimulus that produces the evocative effect.

The function of the affective labelling of experience governing behaviour and the direction of attention may be illustrated by a patient with an obsessional neurosis which in this connexion was a case of singular interest (details of which are to be published elsewhere). In response to a specific word or allusions to it, the patient's blood pressure rose from 185/124 to 230/155. He became extremely distressed, restless and anxious, and tried by every means to avoid the conversation which was for him disturbing. This patient was seen again after he had been subjected to a leucotomy and the rise in diastolic and systolic pressure was then even more rapid and was still sufficiently alarming to prevent mention of the word. By contrast there was, however, a striking clinical change, for there was a noted absence of observed or reported experience of anxiety, though the pressor response was even more marked. There were no attempts by the patient to remove himself from the stimulus as he had done before leucotomy because his protective mechanism utilizing anxiety against a dangerous rise in blood pressure had been interfered with. Focusing of attention cannot simply be governed by the conscious discernment of certain properties of the environment, and the word presumably had a particular unconscious meaning for the patient and was attended to in a particular way because of the subjective experience of anxiety. This is but an exaggeration of the normal process whereby objects are attended to and distinguished one from another by their affective value, differentiation being ultimately impelled by pain/pleasure consideration. This complex and indirect connexion with an objective stimulus could also be said to apply to the cases of reflex epilepsy.

Our discussion has raised certain theoretical questions inherent in any work on conscious human beings. Starting with some considerations that arise out of limited neurophysiological studies it has been necessary to re-appraise the fundamental question of attention and the approach to this problem. The waking state, and therefore consciousness, is conceived of as a theoretic state which is inferred when discrimination is exercised in attending to internal as well as external stimuli; the switching of attention from one thing to another further implies an executive function performed by the ego which organizes information that is not in consciousness (pre-conscious) into a probability hierarchy awaiting entry into consciousness. Einstein[24] concerned himself with the stimulus response problem when he asked, "What, precisely, is 'thinking'? When, at the reception of sense-impressions, memory pictures emerge . . . (and) It is by no means necessary that 'concept' must be connected with sensorily cognizable or reproducible sign (word), but when this is the case thinking becomes by means of that fact communicable . . . For me it is not dubious that our thinking goes on for the most part without use of signs (words) and beyond that to a considerable degree unconsciously" (note, his brackets).

Adrian[25] said that "research has shown how information gets into the brain but not how the brain reacts to it". It is apparent from physiological studies that sensory input is always the same, from whatever organ, so that it is the arrival point that determines whether we see or hear, and contact with reality is necessarily retrospective. But to determine what in consciousness we see or hear, we have to be concerned with the psychological aspects of attention or inattention based on representations that are an amalgam of sensory input, past experience and symbolization Psychical reality consists therefore of very individual representations The focus of attention is the product of these factors and in the process the peripheral receptors may be affected[26] The relating of psychical to physiological events is therefore necessary in neurophysiological experiments. The usual causal equation of objective stimulus and objective response lacks the interposition of the psychical stimulus with the mental and emotional reactions This leads us to consider the terms that have to be used to describe such observations Generalizations based on these accounts require the use of psychoanalytic conceptions, to avoid the too-ready assumption that there is a simple psychological event directly accounting for a physiological change

Thus we are led to suggest that there are complementary points of view that are both necessary for the understanding of perceptual processes In such experiments we have two observers· the experimenter with his objective recordings, and the subject who is an introspective observer who attempts to report on the content of consciousness, that is, that on which attention is focused Since the latter's account is retrospective, he necessarily uses complementary terms to describe a state of mind, at the same time being subject to a continuous experience Philosophical issues concern us less than the epistemological difficulties of dealing with two such streams of information and the attendant problems of communication

AMINO-ACID SEQUENCE OF HORSE HEART CYTOCHROME *C*

Peptides released by Digestion with Chymotrypsin

THE only part of the amino-acid sequence of cytochrome *c* which has been established so far is the region to which the hæm is attached[1] through thioether bonds between the two cysteine residues in the peptide chain and the side-chains of the protoporphyrin[2] Since the conformation of the entire protein has a profound influence on the enzymatic and physico-chemical properties of the prosthetic group[3], an understanding of the interplay of structure and function in cytochrome *c*, as well as of its reactions with other components of the terminal oxidation chain, must be based on an accurate knowledge of the entire protein As a first step towards the elucidation of the structure of cytochrome *c*, a study of its complete amino-acid sequence was undertaken The present communication discusses the peptides recovered from chymotryptic digests of horse heart cytochrome *c*.

Methods and Amino-acid Sequences of Peptides

Horse heart cytochrome *c* (ref 4) was purified by twice chromatographing on 'Amberlite *IRC*-50' (ref 5) Chromatographic fraction I, the enzymatically fully active protein, containing 0 45 per cent iron, was denatured in 60 per cent ethanol The lyophilized denatured protein (100 µmoles) was digested at room temperature for 29 hr with a twice-recrystallized chymotrypsin preparation which exhibited no detectable tryptic activity The mixture was maintained at *p*H 7 8 with an automatic titration apparatus, and 2 per cent by weight of chymotrypsin was added three times during the course of the digestion The complete digest was chromatographed at 40° on a column of 'Dowex 50 × 2' 3 7 cm × 150 cm with volatile pyridine–acetic acid buffers by applying a linear gradient of *p*H and ionic strength from 0 2 *M* at *p*H 3·1 to 2 0 *M* at *p*H 5 0 The peptides in each fraction were purified further by various combinations of electrophoresis and chromatography on paper The amino-acid composition and the purity of each peptide isolated were determined by analysing suitable aliquots after acidic or enzymatic[6] hydrolysis on the automatic amino-acid analyser of Spackman, Stein and Moore[7] All purification steps were guided, and their efficacy monitored, by use of the two-dimensional electrophoresis-chromatography technique of Ingram[8] The yields of peptides were calculated from the analytical data on the final

Table 1. PEPTIDES OBTAINED FROM HORSE HEART CYTOCHROME *c* BY DIGESTION WITH CHYMOTRYPSIN

No. –*C**	Sequence	Yield (per cent)
XIX*a*	Acetyl (Asp,Gly) Val Glu Lys.Gly Lys Lys Ileu Phe (N-terminal peptide)	94
XXXIII*a*	Val Glu-NH$_2$ Lys Cys Ala Glu-NH$_2$ Cys.His Thr Val Glu Lys Gly Gly Lys His haem	60–70
XXV*a*	Lys Thr Gly Pro Asp-NH$_2$ (Leu,His) Gly Leu Phe	63

* Peptides are designated by the prefix *C* to indicate their origin from a chymotryptic digest. The fraction number indicates the sequence *of elution from the ion exchange resin*

products and thus represent only minimal values, in some cases probably as much as 25–30 per cent less than the actual yields, because of variable losses during purification and because the original column chromatographic fractions were pooled to obtain as pure fractions as possible.

The amino-acid sequence of each peptide was established by combinations of chemical and enzymatic methods appropriate to each particular case. The chemical procedures used were the dinitrophenylation technique of Sanger[9] for the identification of amino-terminal residues and the Edman method[10] for the sequential identification of amino-acids in peptides. At each step of the Edman procedure, in addition to the chromatographic identification of the phenylthiohydantoin of the *N*-terminal amino-acid, an aliquot of the residual peptide was hydrolysed and its amino-acid composition quantitatively established. Digestion with leucine aminopeptidase[11] or with carboxypeptidase *A* often permitted identification of *N*-terminal and *C*-terminal residues or short sequences, respectively. When digestion of peptides with endopeptidases, such as trypsin and papain, was performed, the resulting derived peptides were purified and the composition and sequence of each one were established by the methods already cited.

The sequences of the chymotryptic peptides isolated from horse heart cytochrome *c* are listed in Table 1. Except for the hæm peptide, the peptides given in Table 1 are only the longest peptides isolated; in most cases shorter peptides were obtained in much higher yields than the 'overlapping' long peptides. The yields cited represent the sum of the yields of the shorter and longer peptides included in a given sequence.

In the column chromatography of the original chymotryptic digest, the main hæm-containing peptide could not be eluted from the 'Dowex-50' resin. It was prepared from another digest by column chromatography on 'Amberlite *IRC*-50'. Since the enzymatic hydrolysis in this experiment was not carried to completion, the hæm peptide obtained was larger than the hæm peptide of which the amino-acid sequence is given in Table 1 and which represents the minimal chymotryptic 'core' of cytochrome *c*.

The peptides recovered from the chymotryptic digest represent the entire amino-acid complement of horse heart cytochrome *c*, the composition of which was determined by analysis of acid hydrolysates (Margoliash, E., Hill, R. L., Kimmel, J. R., and Schmidt, W. R., paper in preparation): Try, 19 Lys, 3 His, 2 Arg, 3 Asp, 5 Asp-NH$_2$, 10 Thr, 9 Glu, 3 Glu-NH$_2$, 4 Pro, 12 Gly, 6 Ala, 2 CySH, 3 Val, 2 Met, 6 Ileu, 6 Leu, 4 Phe, 4 Tyr. The amide distribution was determined on enzymatic hydrolysates.

N-terminal and C-terminal Sequences

The first peptide listed in Table 1 behaved abnormally. It contained three lysyl residues and one each of glutamic acid and aspartic acid and would, therefore, be expected to have an overall positive charge at near neutral *p*H values; however, on electrophoresis at *p*H 6.5, it behaved as a neutral compound, indicating that either one positive charge had been eliminated or an extra negative charge added. The lysyl residues all had normal unsubstituted ε-amino groups, since digestion with trypsin resulted in practically quantitative yields of all four peptides expected. Moreover, the lysine residues were recovered as ε-dinitrophenyllysine after treatment of the peptide with fluorodinitrobenzene. On the other hand all attempts to identify an *N*-terminal residue failed, indicating that there was no free α-amino group. Thus, the peptide could not be digested with leucine aminopeptidase at ratios of enzyme to substrate fully effective for all other peptides, no *N*-terminal residue could be recovered after prolonged dinitrophenylation, two successive steps of the Edman procedure did not release any phenylthiohydantoin derivative and did not result in any change in composition of the residual peptide. Gas chromatography of a suitable acid hydrolysate established the presence of acetic acid, and it was concluded, therefore, that the amino-terminal α-amino group was acetylated. This finding explains the abnormal charge of the peptide. Incubation of the peptide in methanolic 1 *N* hydrochloric acid gave a mixture in which only aspartic acid and glycine could be identified as amino-terminal residues by the Edman procedure, thereby placing these residues at the amino-terminal end.

Since this peptide had an acetylated α-amino group, it must represent the amino-terminal sequence of cytochrome *c*. This assignment of position was fully substantiated by the work of Kreil and Tuppy and when the entire amino-acid sequence of the protein was determined (see following communications). Similarly, acetylated amino-terminal α-amino groups have been shown to occur in other proteins, for example, melanophore-stimulating hormone[12], in tobacco mosaic virus protein[13], in egg albumin[14], and in turnip yellow virus protein[15].

The amino-terminal residue of horse heart cytochrome *c* has been reported by one of us (E. M.) to be histidine[16] and by another group of investigators to be arginine[17]. Both these claims are erroneous, since the three histidyl residues and the two arginyl residues in the molecule have now been located in the interior of distinct chymotryptic peptides that must be located in the portion of the protein carboxyl-terminal of the hæm

The last peptide listed in Table 1 has a carboxyl-terminal glutamic acid Clearly this residue could not represent a possible point of attack for either chymotrypsin or trypsin Moreover, no longer sequence of which this peptide was a part could be found The last peptide listed in Table 1 was assigned, therefore, to the carboxyl-terminal position in the protein This conclusion is in accord with the results of Titani, Ishikura and Minakami[18] who identified glutamic acid as the carboxyl-terminal residue of horse heart cytochrome *c* by the hydrazinolysis method Similar findings have also been obtained by Kreil and Tuppy (see following communication)

In summary, the amino-acid sequences of the peptides obtained by digestion of horse heart cytochrome *c* with chymotrypsin have been determined and these peptides account for the amino-acid composition of the protein There is no free α-amino group in the protein The amino-terminal residue occurs as the acetyl derivative The amino-terminal chymotryptic peptide has the structure Acetyl (Gly, Asp) Val Glu Lys Gly Lys Lys Ileu Phe The carboxyl-terminal residue is glutamic acid with the terminal chymotryptic peptide having the sequence Lys.Lys Ala Thr Asp-NH_2 Glu

While this work was in progress, we learned from Prof H Tuppy that an investigation of the tryptic peptides of cytochrome *c* was under investigation in his laboratory; it is a pleasure to acknowledge the co-operative exchange of information which has led to simultaneous and joint publication of results We are indebted to our associates, Dr A Light and Dr J R Kimmel, for their help and advice This investigation has been aided by research grants from the National Institutes of Health, U S Public Health Service

A complete description of our work will be submitted for publication in the *Journal of Biological Chemistry*

Peptides, Terminal and Internal, released by Digestion with Trypsin

According to recent analyses, horse heart cytochrome *c* contains 2 arginine (refs 1–4) and 18 (refs 1, 2, 4) or 19 (ref 3 and preceding communication) lysine residues per molecule Tryptic digestion was therefore expected to yield 21 or 22 fragments However, since the commercial trypsin used (Worthington, twice cryst) exhibited a slight chymotryptic activity, a greater number of peptides was obtained In order to minimize chymotryptic activity, the enzyme was pre-treated with dilute hydrochloric acid[5] and the duration of the enzymatic digestion of cytochrome *c* was reduced to 2 hr. The peptide mixture obtained was resolved on sheets of Whatman paper 3 *MM* with the help of a two-dimensional 'finger-printing' technique very similar to that introduced by Ingram[6] The peptides were located with the help of ninhydrin or by observing the fluorescence which appeared on heating the sheets at 105° for 10 min (ref 7) The resulting peptide pattern is shown in Fig 1

For the qualitative determinat on of their amino-acid composition, the peptides from one sheet were eluted, hydrolysed with 5 7 *N* hydrochloric acid (containing 1 per cent thioglycollic acid in the case of peptides containing methionine), and the hydrolysates were analysed by paper chromatography (Table 1) When larger amounts of peptide were required for end-group determination by the dinitrophenyl method and for sequential analysis, the material eluted from several 'fingerprints' was combined Alternatively, a larger-scale resolution of the peptide mixture obtained on tryptic digestion was carried out in two consecutive steps 8-mgm. portions of the digest were first subjected to one-dimensional paper electrophoresis so as to give a series of fractions of different mobility, corresponding fractions eluted from several electrophoretic runs were then combined and purified by chromatography on Whatman 3 *MM* paper

The methods used for elucidating the amino-acid sequence in most of the peptides occurring in the tryptic digest of horse cytochrome *c* (Table 1) were, largely, the classical ones introduced by Sanger, such as end-group determinations and partial hydrolysis by acid and by various enzymes, followed by characterization of the resulting smaller fragments

Special attention was given to the peptides occupying *N*- and *C*-terminal positions in the polypeptide chain of cytochrome *c* The search was stimulated by the fact that numerous attempts to identify an amino-acid carrying a free α-amino group had been unsuccessful (Paléus, S , and Tuppy, H , unpublished work) Earlier reports claiming a histidine[8] or an arginine residue[9] to be *N*-terminal could not be confirmed.

In the tryptic digest of horse heart cytochrome *c*, a peptide (*T*-20) was observed which gave a very weak ninhydrin colour and which was devoid of a free α-amino group Cleavage by pepsin resulted in a tripeptide, Val-Glu-Lys, and an acidic fragment which failed to react with ninhydrin The latter, on total acid hydrolysis, gave glycine and aspartic acid, whereas partial hydrolysis with 2 *N* hydrochloric acid (40 min , 100°) yielded the dipeptide Gly Asp, heating at *p*H 2 (90 min , 105°) produced free aspartic acid and a substance chromatographically indistinguishable from acetylglycine, hydrazinolysis gave aspartic acid and two hydrazides behaving like glycyl-

Table 1 PEPTIDES FROM TRYPTIC HYDROLYSATES OF HORSE CYTOCHROME *c*

	Amino-acids in the hydrolysate*	Proposed structure †	Remarks
T-20	Asp,Glu,Gly,Lys,Val	Acetyl-Gly-Asp-Val-Glu-Lys	*a*
T-2	*Gly*,Lys	Gly-Lys-Lys	*b*
T-4	*Gly*,Lys	Gly-Lys	
T-12	Glu,*Ileu*,Lys,Phe,Val	Ileu-Phe-Val-GluN-Lys	*c*
Hæm peptide	Ala,*Cys*,Cys,Glu,His,Lys,Thr,Val	Cys-Ala-GluN-Cys-His-Thr-Val-Glu-Lys (18)	
T-6*a*	*Gly*,Gly,Lys	Gly-Gly-Lys	*d*
T-2*a*	*His*,Lys	His-Lys	*b*
T-10*a*	Arg,Asp,Gly,His,Leu,Phe,Pro,*Thr*	Thr-Gly-Pro-AspN-Leu-His-Gly-Leu-Phe-Gly-Arg	*e*
T-17	Ala,Asp,Glu,Gly,Lys,Phe,Pro,*Thr*,Thr,Tyr	Thr-(Ala,GluN,Gly,Pro)-Phe-Thr-Tyr-Thr-(Ala,Asp)-Lys	*f*
T-6*b*	*Asp*,Lys	AspN-Lys	*d*
T-11*a*	*Gly*,Ileu,Lys,Thr,Try	Gly-Ileu-Thr-Try-Lys	*g*
T-19	Asp,*Glu*,Glu,Leu,Lys,Met,Pro,Thr,Tyr	Glu-(Glu,Thr,Leu)-(Glu,Met)-Tyr-Leu-Glu-AspN-Pro-Lys	*h*
T-11	Gly,Ileu,Lys,Pro,Thr,*Tyr*	Tyr-Ileu-(Pro,Gly)-Thr-Lys	*i*
T-12*b*	Ala,Gly,Ileu,Lys,*Met*,Phe	Met-Ileu-Phe-Ala-Gly-Ileu-Lys	*k*
T-1	*Lys*,Lys	Lys-Lys	
T-8*a*	Arg,Glu,*Lys*,Lys,Thr	Lys-Lys-Thr-Glu-Arg	*l*
T-8	Arg,Glu,*Lys*,Thr	Lys-Thr-Glu-Arg	
T-15	Arg,Glu,*Thr*	Thr-Glu-Arg	
T-19*a*	Ala,Asp,*Glu*,Ileu,Leu,Lys,Tyr	Glu-Asp-Leu-Ileu-Ala-Tyr-Leu-Lys	*m*
T-18	*Ala*,Asp,Glu,Thr	Ala-Thr-AspN-Glu	*n*

Peptides are designated by the prefix *T* to indicate their origin from a tryptic digest

* The *N*-terminal amino-acid determined by the dinitrophenol method is given in italics

† Where amino-acids have been enclosed in brackets, neither their order nor molar ratio has been determined.

(*a*) Pepsin treatment gave acetyl-Gly-Asp and Val-Glu-Lys

(*b*) The peptides *T*-2 and *T*-2*a* were separated by electrophoresis at *p*H 6 4

(*c*) Chymotrypsin, pepsin and subtilisin produced the same fragments (Ileu,Phe) and Val-GluN-Lys On partial hydrolysis (Ileu,Phe,Val) was formed in good yield

(*d*) The mixture of *T*-6*a* and *T*-6*b* could be resolved by electrophoresis at *p*H 2

(*e*) Chymotrypsin split *T*-10*a* into two peptides Gly-Arg (*T*-5) and (Thr,Gly,Pro,AspN,Leu,His)-Phe (*T*-12*a*) Degradation with subtilisin gave Thr-(Gly,Pro,AspN), Leu-His, Gly-Leu, (Gly,Leu,Phe), free Phe and Gly-Arg *T*-12*a* was further degraded with pepsin yielding (Thr,Gly,Pro AspN,Leu) and (His,Gly,Leu,Phe) Partial hydrolysis of these two fragments gave (Thr,Gly), (Gly,Pro), (Gly,Pro,Asp,Leu), (Asp,Leu), (His,Gly) and (Leu,Phe)

(*f*) Chymotrypsin gave rise to Thr-(Ala,GluN,Gly,Pro)-Phe,Thr-Tyr and Thr-(Asp,Ala)-Lys In a peptic hydrolysate of *T*-17 the presence of (Tyr,Thr,Ala,Asp)-Lys was established

(*g*) Chymotrypsin split *T*-11*a* into Gly-(Ileu,Thr)-Try and free Lys. In a partial hydrolysate (Gly,Ileu) was found in addition to free amino-acids

(*h*) Chymotryptic cleavage gave (Glu,Thr,Leu,Met)-Tyr and (Leu,Glu,AspN,Pro)-Lys (*T*-14) Peptic cleavage gave (Glu$_2$,Thr,Leu), (Met, Glu), (Met,Glu,Tyr,Leu and (Glu,AspN,Pro)-Lys Partial hydrolysis of *T*-14 gave (Leu,Glu) and (Pro,Lys)

(*i*) Cleavage by subtilisin gave Tyr, (Ileu,Pro,Gly), (Ileu,Pro,Gly,Thr,Lys) and Thr-Lys (Tyr,Gly,Pro,Ileu), (Ileu,Pro,Gly) and Thr-Lys were identified in partial hydrolysates Tyr and Ileu were released from *T*-11 under the action of 'oxytocinase' (ref 16)

(*k*) Degradation with chymotrypsin yielded (Met,Ileu)-Phe and Ala-(Gly,Ileu)-Lys Partial hydrolysis of the latter gave (Ileu,Lys) and traces of (Gly,Ileu,Lys)

(*l*) Tryptic cleavage gave Lys-Lys (*T*-1), Thr-Glu-Arg (*T*-15), free Lys and (Lys,Thr,Glu)-Arg (*T*-8)

(*m*) Chymotrypsin cleavage yielded (Ala,Glu,Asp,Ileu,Leu)-Tyr (*T*-2I) and Leu-Lys (*T*-9) *T*-21 was further degraded with pepsin, the resulting two peptides being Glu-Asp-Leu and Ileu-Ala-Tyr

(*n*) Glu is *C*-terminal (hydrazinolysis) Subtilisin cleavage gave Ala-Thr and AspN-Glu Ala, (Thr,Asp,Glu) and (Thr,AspN,Glu) were found in partial hydrolysates

hydrazide and acetyl-hydrazide *T*-20 is, therefore, taken to be AcetylGly Asp Val Glu Lys and to represent the *N*-terminal portion of cytochrome *c* Thus, cytochrome *c* can be added to the growing list of proteins and polypeptides characterized by an acetylated *N*-terminal amino-acid residue, namely, the proteins of tobacco mosaic[10], cucumber 4 (ref 11) and turnip yellow mosaic virus[12], porcine α-melanocyte-stimulating hormone[13], and bovine fibrinogen[14].

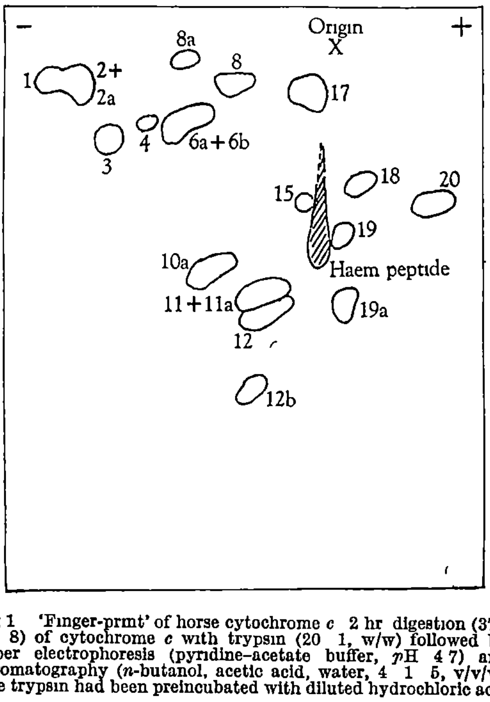

Fig 1 'Finger-print' of horse cytochrome *c* 2 hr digestion (37°, *p*H 8) of cytochrome *c* with trypsin (20 1, w/w) followed by paper electrophoresis (pyridine-acetate buffer, *p*H 4 7) and chromatography (*n*-butanol, acetic acid, water, 4 1 5, v/v/v) The trypsin had been preincubated with diluted hydrochloric acid

When trypsin virtually free of chymotryptic activity was used for the digestion of horse cytochrome *c*, all the fragments arising in good yield contained *C*-terminal lysine or arginine, except for one (*T*-18) the *C*-terminal residue of which, as determined by hydrazinolysis, proved to be glutamic acid Glutamic acid had previously been reported by Titani *et al* [15] to be in the *C*-terminal position in horse cytochrome *c*, a finding that we could readily confirm This obviously suggests that *T*-18, the structure of which has been determined to be Ala Thr AspN Glu, is derived from the *C*-terminus of the polypeptide chain of horse cytochrome *c*

While this work was in progress, we learned from Prof E. L Smith that an investigation of the chymotryptic peptides of cytochrome *c* was going on in his laboratory It is a pleasure to acknowledge the co-operative exchange of information which has led to simultaneous and joint publication of results Full details of this work will be published in *Monatshefte fur Chemie* We wish to thank the Rockefeller Foundation for a grant

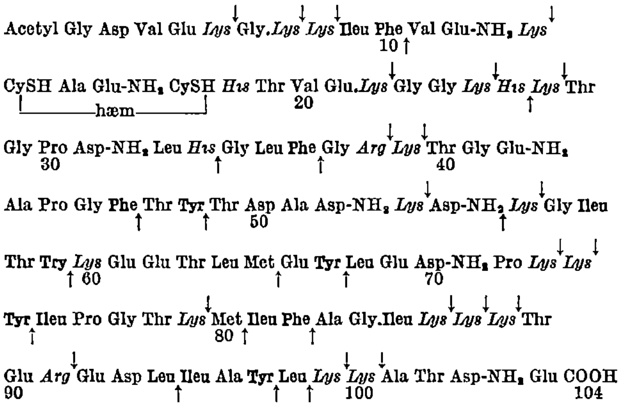
The Complete Amino-acid Sequence

FROM the work reported in the two preceding communications, it became possible to derive a unique amino-acid sequence for horse heart cytochrome *c* This sequence of 104 amino-acid residues, together with the major points of hydrolysis by chymotrypsin and trypsin, is given in Fig 1



Acetyl Gly Asp Val Glu *Lys* Gly.*Lys* *Lys* **Ileu** **Phe** Val Glu-NH₂ *Lys*

Fig 1 Amino-acid sequences of horse heart cytochrome *c* The arrows above and below the line indicate the points of hydrolysis by trypsin and chymotrypsin, respectively The basic residues are in italics, the hydrophobic residues are in bold-faced type

In the following discussion the numbers used to identify the peptides recovered from cytochrome *c* after digestion with chymotrypsin and trypsin will be preceded by the letters *C* and *T*, respectively The assignment of the sequence, as shown in Fig 1, is based on the 13 largest peptides obtained from the chymotryptic digest[1] and the 20 peptides separated from the tryptic digest[2] as follows

Peptides *C*-XIX*a* and *T*-20 both contain the *N*-terminal sequence of the protein, since the *N*-terminal α-amino group of both these peptides is acetylated Peptides *T*-20, *T*-2 and *T*-4 are portions of the amino-acid sequence of *C*-XIX*a*, whereas *T*-12, Ileu Phe - Val Glu-NH$_2$ Lys, contains the *C*-terminal two residues of *C*-XIX*a*, Ileu Phe and three additional residues Indeed, the only other peptide from the chymotryptic digest containing an Ileu Phe sequence is the dipeptide *C*-XIV*a*, obtained in 53 per cent yield, if *C*-XIV*a* were to represent the *N*-terminal portion of *T*-12 it would have to be preceded by a residue which affords a bond highly sensitive to both chymotrypsin and trypsin, which is an unlikely possibility Moreover, *C*-XIV*a* was afterwards located in the interior of *T*-12*b* in the sequence Met Ileu Phe, which explains the release of Ileu Phe in good yield by chymotrypsin

The protein contains three valine residues, all of which are present in a Val Glu Lys sequence Two of these sequences are in the hæm peptides obtained from chymotryptic and peptic digests (ref 1 and preceding communication), whereas the third is in the *N*-terminal sequence present in *C*-XIX*a* Since *T*-12 continues *C*-XIX*a*, the latter is necessarily followed by the hæm peptide resulting from digestion with chymotrypsin, which like the hæm peptide from peptic digests has the *N*-terminal sequence Val Glu-NH$_2$ Lys Of the three Val Glu Lys sequences, the *N*-terminal sequence of the hæm peptide is the only one which contains a glutaminyl rather than a glutamyl residue, further strengthening this conclusion It should be noted that peptide *T*-6*a* with the unique sequence Gly Gly Lys is part of the *C*-terminal portion of the chymotryptic hæm peptide The above argument thus establishes the sequence of the protein from the *N*-terminal end to residue 26
